The original stock should always be strong and healthy. Named varieties are in many cases propagated by side shoots and by cuttings of well ripened shoots. Seeds generally give new and interesting forms. If thinning, as described above, is carried out, plenty of material will be available as cuttings. These should be inserted in pots, pans, or even boxes containing sandy soil, and placed in a frame or a cool greenhouse. When rooted, the cuttings will provide plants for next year. The raising of the plants from cuttings is probably the best method of propagation and is employed by almost all growers and raisers. When well established they should either be planted out where they are finally to remain and bloom, or else placed in a larger pot in the conservatory. They make ideal plants for the latter when other coloured flowers are rather scarce.

A CHARMING BORDER OF PHLOXES ADMIRABLY SUITED FOR SUCH A CORNER.

When planting out, some sort of colour scheme should be borne in mind, and the heights of the different varieties must not be forgotten. The colours should also be taken into account, such as reds (which are most frequent), purples, whites, pinks and salmons. From a horticultural point of view, they are generally thrown into five or six groups, such as the annual phloxes, the perennial, the summer phloxes of nurseries and gardens, the moss pinks, so useful in forming carpets, dwarf phloxes, for which the front of the border should be reserved, and finally, those useful in alpine and rock gardening. Their planting should not be too formal, although sometimes they are specially desirable when colour display is sought for in connection with a formal or semi-formal design as on a terrace. The clumps, however, on the other hand, should not be allowed to become large and straggly, as the flowers on such plants are never first-rate, and a few good trusses make for a much finer effect than a multitude of stunted ones. When staking, too many shoots should not be tied to one stake, and it is not

Digitized by Google

THE DWARF WHITE PHLOX LA NEIGE.

Apart from its value as a decorative plant in the garden, it is excellent as a cut flower when placed in a vase, as its fragrant and bright coloured blooms are greatly appreciated in the house. The fragrance of the phlox is generally found to be sweeter when one is having a stroll through the garden at dusk, or even after darkness has just descended. It is strange why the scent of phlox, like that of so many other plants should be more noticeable at night. Perhaps it may not be due so much to the plant as to the person, whose olfactory organs may function better at night.

There are scores of excellent varieties in commerce, each with its own special appeal to the onlooker or intending purchaser, and everyone should be able to have their slightest whim satisfied. It would only be invidious, then, to attempt a selection, and I will not try to do so. Sufficient is it to say that, as a group, they rank among the most satisfactory of garden plants. Their neat habit, trusses of bright and gaily coloured flowers, and their easy cultivation and propagation should make them universal favourites. G. C. TAYLOR.

necessary to have long stakes towering above the plants. The main object in staking is simply to prevent the shoots from being blown down by wind and rain.

CAPE PELARGONIUMS

A GROUP OF VERY ATTRACTIVE FORMS AND HYBRIDS WHICH SHOULD HAVE AN INTENSE INTEREST AND FASCINATION FOR THE REAL PLANT LOVER. THEY ARE A VALUABLE ASSET TO THE CONSERVATORY.

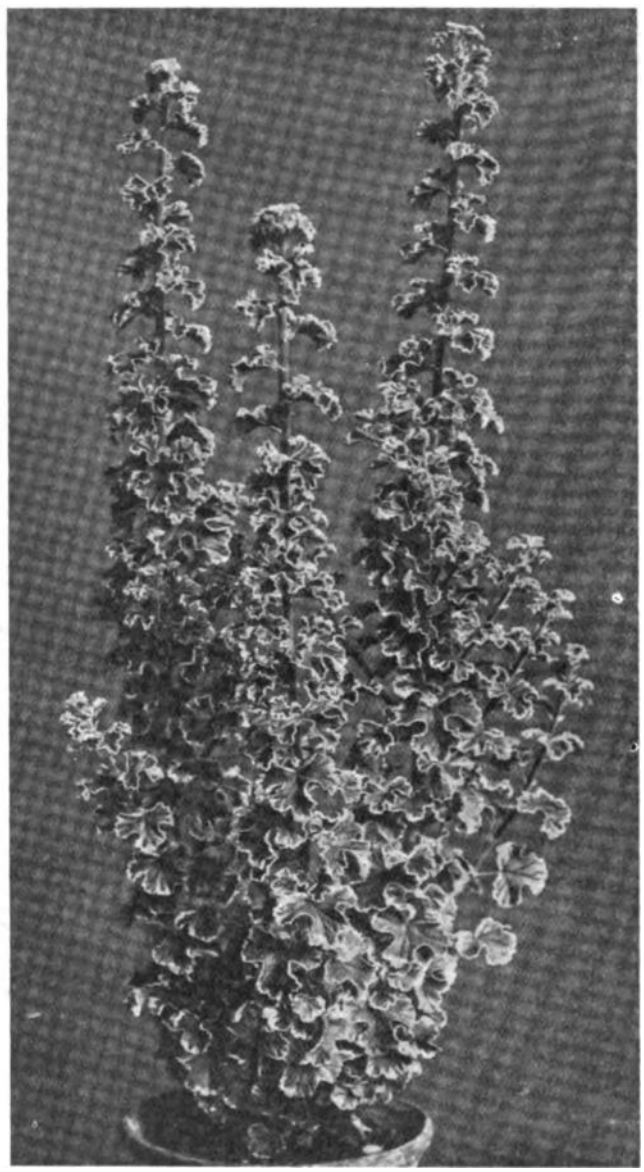
IT is recorded that the first of the Cape or scented-leaved pelargoniums reached this country from South Africa in the year 1632, in the form of Pelargonium triste, and during the period of nearly three centuries that have followed, numbers of species and varieties have been arriving at intervals, many coming to England during the activities of the Naval forces at the Cape in the latter years of the eighteenth century. Naval and military travellers have greatly added to the plant riches of Great Britain, and in this group we, no doubt, can trace many of the varieties to this source. At Aldenham we have the pleasure of over 150 species and varieties, many of which are original species, while a number are improved forms of hybrid origin that have been raised by devoted admirers in various parts of the country. It is strange how the fashion of plants changes, for, whereas, in the Victorian era, "scented leaves" were very great favourites, there came a day when they were, with few exceptions, only to be found in the little homes of faithful cottagers. Now, once again, they are coming to the fore, trusted old friends, returned to favour, until it seems that a boom period is likely to occur; but, alas! how many of this fine family may have disappeared altogether during the period of their retirement. Why they should have been so neglected seems passing strange, for, while they are unquestionably most interesting, beautiful and fragrant, with numerous uses, they demand but little

PELARGONIUM PRINCE OF ORANGE.

Digitized by Google

troublesome attention. Provided they are afforded shelter from frost during the winter period—the low limit of the temperature for them then is only 45° Fahr. for the tuberous-rooted forms and 40° Fahr. for the evergreen sorts—and the necessary cultural attention applicable to them, they thrive merrily on.

Some of them are tuberous-rooted, some greenhouse herbaceous, but the large proportion are evergreen shrubs in character, and we need only consider the first and the last groups for general purposes in these notes. The soil for both is the same compost of four parts good sandy loam, one part leaf-mould, one part spent manure, and a sufficiency of sand to keep the whole porous. Some are more difficult as to soil conditions, requiring a peaty leaf-mould and sand mixture, but they are few and far between. Watering during the summer months is important, and should be freely carried out from March to September, but at other periods should be considerably lessened for the evergreen sorts, and practically checked for the tuberous. Ventilation should be of the freest character at all times when the weather is suitable, all the year round, and the best temperature for them in the summer is from 55° Fahr. to 65° Fahr., so that efforts should be made in very hot spells to keep them cooler than the atmosphere generally will allow. A little stimulating liquid, such as weak manure water, and an occasional dusting with Clay's Fertiliser, are of great benefit for the evergreen forms, and when they have finished flowering the growths should be lightly pruned back. Tuberous rooted forms to develop their best efforts should be repotted each year after flowering, preferably in the spring, and increase of the stock can then be attained by division into suitable sized portions, which should then be potted up in receptacles of proper size to hold them, making fairly firm when so doing. The evergreen forms can be increased by cuttings. When the annual trimming takes place, the best of the side growths then removed should be selected and, removing most of the leaves, other than a few at the point, the growth should be carefully and cleanly cut through just below a joint. Insert these cuttings singly in 2in. pots, into a suitable sandy compost, only selecting the very healthiest, and making them not more than 3ins. long when finally trimmed. The cuttings may be struck either in a greenhouse or a closed cold frame, and by inserting singly, the cutting can then be potted on immediately the roots are formed, without risk of disturbance to the newly formed roots. When this potting on is finished, in order to promote sturdy healthy growth it is well to nip out the points of the growth and to grow the young plants on, close up to the glass of the house or frame in a temperature of about 45° Fahr. If the plants are required as standards, and such are great favourites with many, this removal of the point should not be done, but the growths should be restricted to one, to which give every encouragement, removing side growths as height is attained, until the plant is as tall as desired, when the point also can be checked as the head of the plant is formed. Pyramids also can be made after this fashion, stopping back the side shoots instead of removing, as the main growth progresses, thus shaping up the plant as it develops. When thus shaped, the plants are ideal for summer bedding schemes; in fact, at Aldenham we have had a long border of the bedding scheme completely filled with only "scenteds," of various sizes and shapes, from tiny plants out of 5in. pots to standards 6ft. tall. Many of the species, whatever shape is required, need the "stopping" treatment, to prevent the formation of ugly plants with too rampant growths.



ONE OF THE MANY FORMS OF BASKET GERANIUMS.

As furnishing for a greenhouse, there are few more charming plants during the summer months than the Cape pelargoniums, and we employ them largely for this work, completely filling a span-roof glasshouse, and often overflowing into another nowadays. Carefully arranged on the benches, having regard to colour of flowers so that they do not clash in their various shades of red, they form a most interesting group, and one that always has a great charm and fascination for our many visitors, for, arranged thus, one is afforded the opportunity of studying them and noticing the wonderful contrasts and variations of leaf shapes, and flowering habits and colours. When used in the bedding scheme, it should be noted that the plants can be left in their pots and just plunged into the soil of the beds, a decided advantage in the saving of time and labour, not only when planting, but also when the period arrives when it is necessary to afford them shelter against frosts, and the bedding scheme falls to be dismantled.

Attempts may be made, by those who have facilities, to raise new and improved hybrid forms. The term "improved" is used in order to impress on the tyro that only to raise plants of equal and lesser merit is a futile and useless business with any plants such as these, for the constant aim must be towards obtaining something better than already exists in the case of hybrids, for a race of mongrels lacking merit will soon tire even their, at first, enchanted raisers. Seed of the pelargoniums may be sown in the usual manner in March, and raised in gentle heat, placing the seedlings up close to glass when through, and attending carefully to the watering, for they have a tendency to damp off in the young stage. Pot on when

Digitized by Google

necessary until such time as the young plants in 48 pots can be placed in the open without risk, to grow sturdily along with a view to flowering the following year, when selection should be made and only those allowed that show an improvement over existing varieties or a new break in character or habit.

It is hardly necessary to attempt a selection of varieties to grow, as they all have their differing interests, but any of the "Unique" hybrid forms are excellent, such as Purple Unique, Rollinson's Unique, White Unique, Scarlet Unique, Shelton Unique; while other hybrid forms are Lady Scarborough, Mme. Nonin, M. Nonin, Mrs. Kingsley, Pretty Polly, Shottesham Pet, Shrubland Pet, Shrubland Rose, Lady Plymouth, Pheasant's Foot, Sandbeck Beauty, Westonbirt, Godfrey's Bride, etc. Of the natural species there are many very interesting forms, such as P. Schottii, with its distinct grey foliage; P. crispum, with small green curly leaves; and the Aldenham variety of this, P. c. variegatum, one of the best variegated plants we have; P. Blandfordianum, a free pale pink flowering variety of good grey foliage; P. ardens, with fiery red flowers, marked at the base of the petals with darker tone; P. pinnatum, with very decorative large finely cut foliage; P. artemisifolium, white flowered and with foliage like the old Wormwood; and so one might run on; but the gathering together of the many other pretty and interesting forms and hybrids may be left to the real plant lover, for whom the group must have a fascination. Incidentally, it has taken nearly thirty years to form our collection, and yet interest in them does not lessen, as each year we make valuable additions.

EDWIN BECKETT.

ROCK GARDEN PLANTS

THE INFLUENCE OF MUTUAL COMPANIONSHIP.

PEOPLE with tidy minds and gardens of irreproachable neatness are sometimes visibly distressed when they are confronted with what appears to them to be a violation of the order of things. A weed or two may be excused, for such accidents are inevitable: the common lot of man since the thorns and thistles of Eden. But why do we allow some plants to indulge in unrestrained conflict one with another, to jostle in an ungoverned crowd, which manifestly must result in a mediocrity in all individuals thus engaged and possibly in the entire elimination of the weaker? A goodly portion of our rock garden presents this obvious lack of discipline, isolated plants consisting for the most part of the newly introduced or those few—very few—individuals which are too exclusive to associate with others.

There are at least two good reasons why we permit and oft-times encourage this overcrowding, as it is sometimes called. In the first place, the soil in many parts is so gritty and sharply drained that it will not support anything less tenacious of life than a house-leek until it is covered with a mat of growth. This latter, by checking evaporation and keeping the soil cool and uniformly moist, renders the root-hold quite congenial to many plants which would in other circumstances certainly languish. Then there are many plants, perhaps the majority, which are never really happy unless they are growing in close company with others. In their case it may not only be a matter of preserving that uniformity of moisture referred to. There seems to be what is vaguely termed root-association, a factor of no little importance in the well-being of some plants, and I would not like to assert that there is no such thing as temperament among plants, some positively suffering from a chronic nostalgia, or loneliness, which a label alone for company will never alleviate.

PRIMULA JULIÆ, A BOON COMPANION TO GENTIANA FARRERI.

If it is not always profitable to copy Nature in the building and upkeep of the average rock garden, Nature does always proclaim the virtues of that mutual companionship between plants to which I have just alluded. The struggle for existence is popularly supposed to mean the destruction of the weak and the survival of the strong; but the process, infinitely slow, means also that it gives to all engaged in it a zest for life that would, in the absence of that factor, be much less manifest, if not quiescent. The feeblest are rendered not more feeble but stronger by having to contend with others for a place in the sun.

To put the matter in another way, one of Nature's most finished products is the sod, whether it is the sod of an alpine meadow, a Devonshire hedge-bank or a Welsh moor. Any naked soil she hastens to cloak with a dense throng of growing things, for, so long as it remains exposed to sun and air, it is as inhospitable to plant life as a desert. And thus we find that in this respect at least one has either to copy Nature and adopt her principles or suffer the consequences which await those who hope to succeed by violating them.

However, the discreet gardener will always salt his judgment with commonsense in deciding how far a plant may be pressed by others, or to what extent companionship will be advantageous to it and its neighbours. The vigorous, such as the thymes, some veronicas, aubrietia and arabis will settle the matter for themselves by quickly covering their allotted space with a mulch of their own foliage. But Gentiana verna and many others of its genus, Dianthus neglectus, Daphne Cneorum, Dryas octopetala, Hutchinsia alpina, most of the silenes, dwarf heaths, alpine phloxes, arenarias and a host of other things delight in rubbing shoulders with their neighbours, if they do not actually yearn for such companionship. Indeed I think you may take it to be a sound rule that all those alpine and other plants which grow naturally in turf, or which cover the ground in dense masses, should always be grown in close association with their own kind or, preferably, some other herbs of suitable stature and kindred nature.

I have referred to mediocrity, or that falling off in quality which may be the outcome of allowing plants too much licence in their ambition to grab their neighbours' quarters; but it certainly

Digitized by Google

does not always follow that close companionship leads to mediocrity in the individual or the general effect. I can, indeed, regard many of our most overgrown, congested and disorderly ledges not only without concern but with the deepest satisfaction and delight. Of course, it may be hopelessly wrong and all that, and it may savour of neglect (a very estimable virtue sometimes), but there it is.

Take, by way of illustration, a hummocky corner planted years ago with Lithospermum prostratum, Hypericum Coris, the false Veronica Bidwillii, some creeping thymes and one or two satureias. All these are now interwoven one with another in the direst confusion, or the happiest freedom, which you will. There is never any lack of interest the season through, and wild horses will not persuade me that a cheerful conglomerate of this kind which never grows a weed or asks any attention should be ruthlessly dismembered and once more lined-up for a fresh start with military precision.

A few shady steps have been given over entirely to two shades of green, the emerald of Acæna Buchanani and the glossy lettuce-green of Helxine Solierolii. The two plants, which are inextricably mixed, ensure a pleasant and entirely weedless verdure the year round, and while the acæna, being practically hardy, gives the helxine just as much protection as it needs, it affords it a timely check in summer. Another acæna, the bronzy microphylla, is doing good service in another way. For years a bush of Daphne Cneorum, flopping over a stone, was obviously ill at ease. It flowered fairly well, but its leafage was poor and it was ugly and leggy. Then the approaching acæna came closer. It got among the daphne. swaddled up its thin, unhappy legs,

THE LOVELY ARENARIA MONTANA GRANDIFLORA MAY BE GROWN AMONG OTHER ROCK PLANTS WITH ADVANTAGE.

and from that day the shrub grew away with a new vigour and it is now one of the best specimens in the garden.

Helichrysum trinerve, which was invited to clothe a rough slope, was not a success, mainly because, having no anchorage for its trailing stems, they were the toys of every wind. But no sooner had Lysimachia Nummularia (the large-flowered form) joined it than it settled down to a peaceful life, and the result is we can not only enjoy the beauty of the helichrysum, but the Creeping Jenny comes into flower when it is over and continues well into autumn. Both plants are thus manifestly the better for the mutual co-operation. Dryas octopetala, already mentioned, we failed to satisfy for years, that is, until the plants became nearly smothered by some creeping veronicas, thymes and a little bush of Hypericum balearicum, since when it has never looked back. Another example of this is afforded by a new bed of Gentiana Farreri, which has on one side several lusty clumps of Primula Juliæ. The gentians nearest the latter are not only much stronger than any of the others, but their boldest and best shoots are those which are almost covered by the leaves of the primula.

There are some plants, of course, which, while they may be grown with advantage among others, cannot be said to afford the latter any benefit. The lovely Arenaria montana grandiflora, serves as an example. Our most successful masses of this charming plant appeared as self-sown seedlings among some rocks about which Cotoneaster congesta and Erica carnea growing together make a dense carpet of dark and light green. Here the sandwort develops into a climber of some pretensions, and while the shrubs are certainly none the worse for bearing such a singularly beautiful burden, their foliage gives the latter the best of all possible backgrounds and a congenial support.

Admitting that there are plants too aggressive to be permitted a free range among choicer things, there are occasions when the ways of the transgressors must be pardoned. I confess to being unable to do away with a large mound of armeria which has become enmeshed by the violet-studded tentacles of Linaria æquitriloba, to which the former appears to be quite indifferent. Then there is Raoulia australis. A showery summer so stimulates this lowly mite that it streams in a grey-white spate that respects nothing which it is able to overflow. Now peppered with

DRYAS OCTOPETALA DELIGHTS IN RUBBING SHOULDERS WITH ITS NEIGHBOURS.

Digitized by Google

its golden knobs, R. australis has just invaded a patch of Sedum origanum, so that the blood red foliage and flower stems of the latter are standing ankle deep in a pool of silver. The stonecrop may suffer and the little usurper may extinguish some small clumps of encrusted saxifrages which it is rapidly veiling with its gleaming filigree. But rather than snub so delightful a creature by banishing it from the ranks of the invaded, risking in the process the probability of doing as much injury to the rescued as to the aggressor, we let raoulia have its way. Winter will visit it with all the chastening it deserves, and, as for the saxifrages and stonecrop, it is a simple matter to give these a fresh start elsewhere. Viewed from such a standpoint, we can regard with delight rather than consternation the weaving of our tapestry of silver and crimson and gold. Whether it is the right standpoint opinions will differ. A. T. J.

SOME RECENT DEVELOPMENTS OF THE BEARDED IRIS

BY SIR ARTHUR HORT, BT.

(*Continued from page* 530.)

NOW, in what follows I hope I shall not be thought too egotistic if I describe how I have attempted to carry on some of the work of the master to whom I owe both the foundation of my collection of plants and many fruitful lessons. Others have worked on similar lines, and, if I mention my own plants rather than theirs, it is simply because I know my own nursery and the history of the infants reared in it. I am familiar with some of the *results* reached by distinguished growers like Mr. Bliss, Mr. Yeld, Mr. Dykes, M. Vilmorin, M. Denis, but, except perhaps here and there, I do not know how their results were reached.

Let us take a few examples, to show how Foster worked and how it is possible to work on his lines. By seeding his new cypriana, sent him from Cyprus, he produced Miss Willmott, a fine creamy white handsomely marked. (He himself, by the way, called this a seedling of Kashmiriana, but experiment seems to have proved that this was a mistake.) This plant, however, is shy-flowering and not a very good doer; moreover, the colour tends to "break," as tulip-growers say, and become faintly streaked with purple. By crossing Miss Willmott with Regan, a very robust child of Trojana and pallida, I produced Bolingbroke, which has all the good points of Miss Willmott, but is taller and more robust and has flowers of purer colour. I have heard it called the best white yet raised, though one Theseus, a casual seedling which turned up in my garden, runs it hard, and so does Kashmir White, a noble seedling of Foster's, which he did not, I think, live to see in flower. Mr. Dykes has just produced a white seedling, which I have not seen and which perhaps beats them all.

Again, from cypriana crossed with pallida, Foster raised several fine things, including Lady Foster, which also did not bloom till after its raiser's death, and Caterina (so called from the Queen of Cyprus), over which our American friends rave; but they complain that it is not robust, and in some of their gardens will not grow at all. Well, from Caterina in my Harrow garden came a whole tribe of seedlings, nearly all of stronger growth than Caterina (which generally has to be tied up) and with flowers not only larger but better built. I can claim no credit for this batch, save that of collecting and sowing the seed, since I had not pollinated the flowers: at that time I did not generally pollinate hybrids, but worked chiefly from wild forms. Some of these daughters of Caterina are getting well known, as Ann Page, Volumnia, Vincentio, Olivia. I have named in all about fifteen of them, all quite distinct, all, in my humble opinion, better than Caterina, and they have the advantage that I have flowers of Caterina type for a lengthened period, as her children bloom at different times. Thus, Olivia does not open till towards the end of June.

Again, from Volumnia, one of these Caterina seedlings, I have Leonato, a grandchild of Caterina: this supplies the frontispiece of Mr. Wallace's List for 1923, and, as he asks 6 guineas for a rhizome of it, I suppose I am not alone in admiring this flower. Again, I have new seedlings growing on of Leonato, a further generation, which may or may not give a further advance: I confess that I hardly expect Leonato to be beaten.

After Foster's death, his widow gave me, with other plants, a scrap of rhizome labelled "Ricardi seedling," namely, a seedling presumably of imported Ricardi, a variety of mesopotamica. This developed into a huge clump with massive red-purple flowers, rather loosely shaped, and bore abundant seed. From this seed, fertilised naturally or artificially, has come another fine race of giants, mostly with stiffer stems than the parent and flowers even larger, but well set up, not floppy. This batch includes Antonio, Eglamour, Shylock, Desdemona and Autolycus—an improved Isoline.

The pollen I used on the Ricardi seedling was chiefly that of vigorous and very hardy germanicas, such as Amas and Purple King, which might be expected to add robustness to the stature and size of the other parent. Pollen of the lovely Lady Foster gave me Desdemona, which seems to be the sturdiest of the batch for English gardens. Trojana, another of Foster's introductions, has a fine, well balanced branching inflorescence, but the stem is weak and the foliage thin and poor. Many hybridisers, such as M. Vilmorin, the raiser of Alcazar, have discovered the value of this plant as a seed-parent or pollen-parent, though, unfortunately, there has been some uncertainty what Trojana is, the name being sometimes given by mistake to a *western* germanica form. The offspring usually have the characteristic much-branched stem, which sets off the flowers. I have known the stem of a Trojana seedling to have ten perfect flowers out on it at once. This plant, by the way, is a puzzle: according to my (pretty careful) labelling it is a seedling of Trojana uncrossed; but, whereas the parent, as I said, has thin weak leaves, the child has the broadest and finest foliage I have ever seen: the branches are produced from spathe-valves sometimes 4ins. across. It is called Hermione. This is what I call a "casual": my deliberate efforts with Trojana have been chiefly with the pollen of Amas: I have a whole regiment of seedlings from this cross, a very strong-growing race of "purple bicolors" with abundant foliage (derived, no doubt, from Amas) and a pleasing range of shades, from Ann Bullen, a rich dark beauty, to Speed, which has almost sky blue standards; others of the batch are Angelo and Mistress Ford.

Pollen of pallida on Trojana produced a plant which I call Regan, and which I cannot distinguish from a thing that I bought as cypriana in the days when I always ordered cypriana on seeing it in a catalogue. I might add a warning that many things masquerade under that name. The true cypriana, given me by Foster from the plant sent him from Cyprus, I fear I have lost, and I do not know where one could be certain of getting it.

In my limited experience these three Orientals—mesopotamica (or Ricardi) cypriana and Trojana—have chiefly contributed to the production of improved garden forms, and I do not doubt that there is much yet to be done with them, especially, I believe, in the way of seeding on to further generations. Unluckily, plants containing blood of mesopotamica or cypriana keep one tiresome characteristic learnt in the higher latitudes from which those species came. I have never known any of them killed by a hard winter, but they are apt to suffer from a mild one followed, as in 1923, by a ferocious spring, because they tend to keep their foliage, instead of dying down decently like the irises of western Europe, and also to try to grow too early; then an April frost damages the foliage and may destroy the flower buds before they emerge. (This is no doubt what has happened with other early-flowering kinds, even the hardiest, in years when they do not flower. Thus, last year even Germania typica failed in my garden, and, as its aspect is south and it is very early, I take this to be the explanation.)

(*To be Continued.*)

FRUIT BOTTLING AT HOME

THE old housewifely art of fruit bottling has come very much to the fore in recent years, due, no doubt, to the necessity for economy and to renewed interest in preserving our own garden fruit for winter use—possibly also to the introduction of the modern "fruit sterilising apparatus."

The bottling of fruit is really quite a simple process, cleanliness and minute attention to detail being the keynotes of success. Whatever the method employed, the underlying principles are the same—(A) Thorough sterilisation—the destruction of any germ in fruit or water productive of mould or fermentation; (B) exclusion of air after sterilisation.

A Fruit Sterilising Outfit, of which there are several reliable kinds on the market, is a useful addition to the kitchen equipment, for it economises time and labour and reduces risk of failure to a minimum. The old-fashioned method of bottling in ordinary jam jars and sealing with fat, parchment covers, etc., is by no means unsuccessful, but it is more laborious, and there is always just the risk of imperfect sealing.

A thermometer, which is supplied with a "fruit sterilising apparatus," is not an absolute necessity for bottling, but the use of one is an aid to success. A dairy or bath thermometer is suitable, but it is advisable to test it before use. Put it in a pan of cold water with the mercury about 3ins. below the surface. When the water boils (212° Fahr.), if the thermometer registers above or below this degree, calculate accordingly when sterilising.

Substitute for Patent Steriliser.—Use an ordinary fish kettle or any pan deep enough (10ins.). A false bottom is indispensable. A meat rack, strips of wood tacked together lattice-fashion, or even a folded teacloth, will answer the purpose. If using a thermometer, to avoid dipping it in and out, make a hole in the lid of the pan and fit into it a piece of rubber or cork with a hole pierced in the middle; this will grip the thermometer and keep it in position.

Bottles with glass caps, rubber bands and metal screw-down rings are largely used, and for hygienic reasons are preferable to those with a metal cap. On the cooling and the contraction of the contents of the jar a partial vacuum is formed within, and this, with the outside air-pressure, fixes the lid tight and seals it hermetically.

GENERAL DIRECTIONS FOR BOTTLING.

Methods vary vastly, but general rules are applicable to all.

(1) Use perfectly clean bottles with wide necks, and pure water.

(2) Fruit must be clean, dry and sound, and should be rather under than over ripe.

(3) If graded as to size and ripeness, space in bottle is economised and fruit is equally sterilised.

(4) Prepare fruit in the usual way, wash and dry, handling and cleansing soft fruits as gently as possible to avoid crushing. Peel, core, halve or quarter apples and pears, and, to preserve colour, drop into slightly salted water as peeled.

(5) *Well fill* bottles, shake the fruit down, pack tightly, but avoid crushing. Two wooden sticks (12ins. long), pointed at one end, are useful in arranging fruit in layers.

(6) Apply heat *very gradually* (see table).

(7) Glass, being a bad conductor, heats unequally and is liable to crack upon exposure to sudden extremes of temperature; hence the use of a false bottom in the steriliser. Never put a hot bottle on a cold surface or leave it in a strong draught, nor let a cold one come into direct contact with hot metal (such as the oven shelf).

(8) *Remove one bottle at a time* from the steriliser or oven and *seal at once*, to exclude air, by which germs gain access to the fruit.

(9) Store in a cool dry place. Strong sunlight is apt to bleach the colour of fruit. Examine bottles occasionally, particularly those covered with paper.

Use of Water or Syrup.—Water preserves the fresh flavour of the fruit better, and sugar can be added when it is used. Fruit bottled in syrup is richer in flavour, but there is greater shrinkage. For a thin syrup dissolve ½lb. of cane sugar in 2 quarts of water, boil for ten minutes, skim, and use when cool. For a thicker and richer syrup, increase quantity of sugar.

Causes of Fruit Rising in Bottles.—(A) Loose packing. (B) Over-heating and heating too rapidly. Fruit must be sterilised, *not* cooked.

Approximate Time and Temperature.—For time and temperature there cannot be a hard-and-fast rule. They depend upon the kind, quality and ripeness of fruit.

Fruit.	*Time.*	*Temperature.*
(1) Soft: Raspberries, Strawberries, Loganberries, etc.	1¼–1½ hrs.	155°–160° Fahr. Keep at this for 5 mins.
(2) Hard: Plums, Damsons, etc.	1½ hrs.	160° Fahr. Keep at this for 5 mins.
(3) Apples and Pears	1½ hrs.	180° Fahr. Keep at this for 5 mins.

Note.—(*a*) During the first hour, bring the water very gradually up to 100°, then gradually during the last thirty minutes up to the required maximum temperature. (*b*) Stone fruits generally crack slightly unless under-ripe.

BOTTLING IN FISH KETTLE OR ORDINARY PAN.

(1) Pack bottles as directed.

(2) Fill with cold water to overflowing.

(3) Put on rubber band and glass cap, and screw down metal ring tightly, then give a half-turn back to allow of expansion within.

(4) Place bottles in pan, do not let them touch, and cover with cold water.

(5) Apply heat very gradually—

(*a*) If using thermometer, proceed according to table.

(*b*) If not using thermometer, more care is required. Heat water very gradually to simmering point and keep it there for twenty to twenty-five minutes. To test, remove one bottle, with a cloth, and gently twist in the hand. If the fruit moves slightly, it is ready. Very tight packing is essential, otherwise this test is no sure proof of sterilisation.

(6) Remove one bottle at a time, and at once screw down the ring tightly.

(7) Leave bottles to get quite cold, and follow directions given.

Note.—If ordinary glass jam jars are used, do not fill so full. Also the surrounding water must only reach to the level of that in the bottle.

METHOD OF BOTTLING SUITABLE FOR SOFT JUICY FRUITS.

(1) Remove the stalks from the fruit—such as raspberries or loganberries; sprinkle with white sugar (or not), and pack as tightly as possible without crushing.

(2) Sterilise in the ordinary way at 160° Fahr. When the fruit has shrunk in its own juice, fill up from another bottle and re-sterilise at 160° for another ten minutes. Seal in the ordinary way.

NOTES FROM CONTRIBUTORS

THE COTTAGE GARDEN.

AS a regular reader of THE GARDEN, I have, with considerable interest read the various articles and studied the designs set forth by expert and practical advisers; but I have noticed that most of the information and instruction given has been more or less for the man of means. The cottage garden in rural districts has been and always will be a source of pride to the owner and a great pleasure to passers-by. Unfortunately, private enterprise to-day is hampered in house-building, and, instead of a variety of designs in cottages, we see, as a consequence, blocks or rows of cottages with much about the same appearance when taking a general view of them. I have no doubt that the schemes set forth are most economical from the Councils' point of view: what cannot be cured must be endured!

I have in my mind a garden city (so-called) of about 400 cottages, wide roads, avenues of trees, which will, indeed, look beautiful

A CHARMING COTTAGE GARDEN.

in a few years' time. The roads and trees are worthy of all praise, but the cottages are all set out in perfectly straight lines, and separated from the roads solely by posts to which has been attached about three strands of wire. They are also separated from each other in precisely the same way. Alas! for poor Mrs. Jones's children when their ball—which, under the circumstances, naturally gets between the wires—breaks Mrs. Smith's prize marigold. The still small voice of Mrs. Smith wafts softly over the breezes and—but we had better leave it at that. I think, with the aid of the Housing Committee, by putting some decent oak palings and gates to each cottage, in an undulating manner, to break the institutional effect of the scheme, the tenants would be encouraged to put forth their best efforts, and the garden city might quickly and easily become a *real* garden city, and not a city minus the garden. These notes are not for the man of means or the professional, but simply for the cottager—a man who cannot afford to employ labour, but who takes a personal interest in his garden. The following notes and photograph will show what a great variety can be got in a small space, in their proper proportions. Readers may criticise and say this or that should be put in large clumps, and I quite agree to that, provided there is plenty of space, so that the effect can be seen from a distance and from an expert's point of view. But my experience of rural life is that the cottager likes a variety, and why should he not have it for lack of space to put big clumps? The accompanying photograph is of a cottage garden, the size of which is 45ft. long by 30ft. wide. The herbaceous border runs the full length and is 6ft. wide. The background is planted with rambler roses trained on wire netting, which also acts as a screen to the vegetable garden. The front has a grass border 1ft. wide. A gravel path leads up to the rustic summer-house, the size of which is 5ft. long, 3½ft. wide and 6ft. high, with climbing roses each side. The rockery is banked against the wall and is planted with aubrietias, alyssums, Sunbeam poppies, ferns, fuchsias, saxifrages, veronicas, violas and irises. The artificial pond has a cement bottom and is 12ft. long, 3ft. wide at its widest point, and spanned by a rustic bridge 6ft. long by 2½ft. wide, with an escallonia trained across it. Round the edge of the pond are planted irises, violas, aubrietias, pinks, veronicas and rock roses. On the right of the pond is planted a pampas grass, and on the left red-hot pokers in the grass. Near the pampas grass is a mound on which is planted, quite in the centre, a broom, at each of four corners a cupressus, and filled in with polyantha roses (Orleans) and Mrs. Sinkins pinks. The small mound in front of the pond is planted with a gypsophila. The rose-beds are planted with roses of various colours, mostly hybrid teas. I have not restricted the herbaceous plants to any particular variety or colour, as that would be getting away from the idea in mind. Real lovers of the English garden admire the individual flowers themselves rather than the blending and harmonising of colour. Planted between the herbaceous plants and on the rockery are crocuses, snowdrops, chionodoxas, tulips, hyacinths and narcissi for spring flowering.

Of course, this is only one idea, but an original one, and it is the original combined with the practical which would make a welcome variety in place of the rather monotonous sameness we behold in our garden cities.—P. E. C.

THE DYER'S GREENWEED.

GENISTA TINCTORIA, recognised as a summer-flowering native shrub of lowly, straggling habit on heaths and commons, is not particularly attractive. But under cultivation it is greatly improved, the flowering spikes being not only longer but branched so as to form well furnished panicles of yellow. Suitable as this is for associating with heaths and such like, its double form (G. t. flore pleno) is a really good rock garden plant. This is, moreover, especially desirable since it does not come into flower until most of the dwarf blooms are over, and its foliage, which forms a dense mat some 4ins. thick, retains its rich green for the greater part of the year. At the time of writing (early July) a large patch of this double variety, growing in poor soil on the top of a very dry retaining wall, is a gorgeous mass of golden yellow, a better colour, by the way, than that of the type or other form of the species. It is interesting to note that the flower-spikes of this broom, having shed their blossoms, become so hardened at the tips that by the time winter comes along they assume what is practically a formidable array of spines, presumably designed to bristle defiance at the prowling rabbit or other browsing animal.

The earliest to flower of the tinctoria group is G. t. mantica. We grow this among heather and other plants in open woodland where it makes a spreading bush about 2ft. high, bearing from May onwards a succession of flower-spikes in a somewhat feeble yellow (for a broom) yet one that is by no means ineffective against the dark green foliage.

The tall-growing variety known as elatior has a stiff, erect habit and may be anything from 2ft. to 6ft. in height. The rather fine flower panicles are raised aloft at the extremities of the upright branches, and when these do not blossom until the later summer, which is often the case, they afford a very welcome touch of just the right note of flaming yellow to harmonise with the first hints of autumn. Although the brooms of the tinctoria set generally will doubtless prosper in the poorest of soil, I am inclined to think that they would repay one for better living and moister conditions than are usually granted them. This is especially true of var. elatior, which if it cannot make sufficient growth during summer may not break into flower until the autumn rains come along.—N. WALES.

NEW ZEALAND PLANTS IN SCOTLAND.

IN these days when so many products of our colonies are being seen and admired at Wembley, it may be a consolation to those of us who have to remain at home to know of others which are more attainable. In the marvellous group of islands known to us as New Zealand, our plants for many years have been acclimatised with the greatest success, and recently plants from there have come to adorn our gardens.

Of these, perhaps the most easily grown and the most decorative is the Senecio Greyii, a shore plant which grows best in the neighbourhood of the sea. Once established its large grey leaves are beautiful all the year round, its buds are like silver balls, and its flowers appear in large panicles—from five to forty in a bunch, of a clear yellow colour contrasting exquisitely with the foliage.

Digitized by Google

From the window where I write I can see three clumps of this fine shrub, two in the sunshine growing to the top of a fence 5ft. high, the other luxuriant in very poor soil under the shade and drip of a large chestnut tree. Given a maritime district it seems to flourish anyhow and anywhere, and it grows very readily from cuttings. After ten years' experience I can heartily endorse Sir Herbert Maxwell's recommendation of it in his recent "Notes from the Garden."

Another beautiful grey plant is Geranium Traversii, which adds a charm all its own to the rock garden. It has a fine glaucous foliage of a trailing habit, and pink flowers larger and brighter than the G. argentum. Old plants cannot survive severe winters, but they seed freely, and the seedlings are very hardy.

Veronicas from New Zealand may also be grown here in great variety. In my own small garden I have quite a number of them. V. Hulkeana, which is said to be somewhat tender, I grow against a wall where its long sprays of lavender flowers were beautiful at the end of May. The hybrid V. Fairfieldii, which flowered about the same time, while also very pretty is not to be compared with Hulkeana. Early in June V. Catarractæ was smothered in white blooms each with a narrow line of pink, and V. Hookeriana was in flower at the same time, its flowers similar to those of V. Catarractæ, its leaves a little broader and larger. V. pinguifolia and V. monticola, both suitable for the rock garden, produced a profusion of white flowers in June, also V. Bidwillii, the smallest of all and fit to mingle with the choicest alpines. In July V. pimeleoides, only 6ins. high, is beautiful, with blue-green foliage and covered with lavender flowers. At the opposite extreme is V. speciosa, which grows in bushes 3ft. or 4ft. high and thrives even in the shade and with a northern exposure. This fine shrub with large leaves and dark purple flowers is now—in July—flowering freely. Other late-flowering varieties are V. parviflora, which has delicate spikes of very pale lavender, V. salicornoides and V. cupressoides, which all thrive here and flower well.

Of hybrids now coming into bloom V. Autumn Glory is the most notable. This will continue to flower on into the winter months. In another garden near here, but more sheltered and with a better exposure many other New Zealand plants have made themselves quite at home. Olearia ilicifolia, O. myrsinoides, and O. macrodonta are all there, and—on a south wall—a number of fine plants of Clianthus puniceus, both crimson and white, make a splendid show this spring in spite of the severe winter. A remarkable hedge of O. Haastii and New Zealand flax—Phormium tenax—the latter throwing out great flowering spikes, is also to be seen there at present among many other wonders from overseas for which one may search in vain through the Great Exhibition.—H. W. L.

CORRESPONDENCE

CALLISTEMON SALIGNUS.

SIR,—I am sending you a photograph of Callistemon salignus, or bottle-brush plant, which has just recently been taken on my lawn.

It blooms every year, and is kept all the year round in a cool greenhouse. I thought perhaps it might be of interest to your readers, since it is not without its unique points and is somewhat of a rarity in these parts.—SAMUEL H. LANE, *Isleworth*.

ANOTHER APPRECIATION.

SIR,—I read with interest the editorial articles of June 14th and July 5th. Being very fond of gardening in imagination as well as in practice I am a subscriber to THE GARDEN and two other gardening papers, and I have sometimes tried to formulate the distinctive characters of the three. It seems to me that THE GARDEN helps a beginner (and that a more advanced gardener would be helped too) to get good general views of gardening possibilities. You give an article on some genus. Well, few of us can grow all its members. But perhaps we grow one, or are encouraged to grow one by your article, and then our specimen stands to us, not as an isolated plant valuable merely for its beauty, but as related to the others of its genus of which you have told us and for which we probably long. Then there are such articles on garden practice as those which have frequently appeared on seed-raising of perennials and alpines. One, on August 18th last, has a most useful table, "When and How to Sow."

There is, I imagine, a public who, like myself, are beginners and amateurs, and we want to be helped along the less commonplace ways of gardening; and we want also that kind of general knowledge which will enable us to go into a fine garden and enjoy it with understanding.—W. R. JOHNSON.

THE CHARM OF A SMALL GARDEN.

SIR,—Permit me as an old reader and an occasional contributor to THE GARDEN to express my great pleasure and gratification upon reading the editorial "written round a correspondent's answer to a short note of a week or two ago entitled "Encouragement." Certainly the introductory page of the issue July 5th (page 460) is most encouraging, and I feel sure will give great pleasure to very many, like myself, who are workers in a small garden. There is certainly great beauty in "simple gardening," equally so to the most extensive, pretentious or ornate forms of gardening. And though we possessors of tiny gardens cannot boast of our orchid houses or extensive rock or alpine gardens, we are enabled to grow to considerable perfection the "poor man's orchids," and I venture to say they are among the most glorious flowering plants in cultivation, and they cost nothing! Upon my border at the present moment there is one of the finest and most noble of foliage plants upwards of 5ft. 6ins. in height, and I think Mr. George Garner will call this one of the simplest forms of gardening, for the plant is only the common iris, the water-flag of our riverside. Then, we cannot form great rock and alpine gardens or alpine meadows in our modest borders, but we can grow some of the most glorious of plants in our borders with equal success to the gardener who has his broad acres and staff of helpers. Not only so, but the small garden of just a few square feet is usually tended by the amateur gardener, and therefore has the great advantage of that "personal touch" that means so much in all gardening either great or small. His plants become to him as personal friends, and as time goes along the most modest of flowers, even the simplest of garden flowering plants like the daisy, talk to us and we to them and, like Francis Thompson, we also are enabled to see "the bitter in the sweet and the sweet in the bitter" as we labour year by year in our "simple gardens." Oh! I can assure every reader of THE GARDEN that there is great charm and pleasure in the study and contemplation of the smallest of Nature's treasures as we work on our tiny plots. My own experimental plot is not more than 44 square yards in

THE "BOTTLE-BRUSH" PLANT.

Digitized by Google

extent, yet even here this small space has enabled me to carry out many forms of gardening and to contemplate the inner meaning of flowers and gardens. There are no more potent factors in the world for good than flowers and music, "and by the aid of gardens and good music," I am assured by the governor of one of our great penal establishments that he can reach the hearts of men who are considered beyond the pale of human society, and I have seen the same for myself, therefore one is assured that the charm of a small garden is real and abiding, and I gladly welcome the page upon "Simple Gardening." The charm of a small garden is this, there is no finality. Of necessity it is ever changing, and by the time the borders are planted and finished from end to end the plants have matured and been photographed in endless stages of growth. One may with pleasure and advantage commence again and rebuild our rock borders, introduce plants that we have not hitherto grown, and so the changes may be rung in endless ways, and our garden education is gradually evolved from the simple—shall I say to the beautiful. And this gradual knowledge and garden craftsmanship is largely the result of our wonderful British garden journals and the valuable information that one finds just of use as one refers to them as guides or text books. Need I say more than this: That for years we have taken four garden papers, and THE GARDEN for upwards of twenty years has been to me as a personal guide and friend, and with the new issues and extra features, not overlooking the exquisite and superb quality of the illustrations, I shall feel an added interest, and most sincerely wish the Editor and all those concerned in its production great success in the publication of THE GARDEN.

One final word. Have you noticed that the present issue is No. 2751? and through all the years week by week gardening has been the subject written upon, and one wonders that the topic has not "run dry." Truly, gardening is a hardy perennial, ever new, and that is the especial charm in either gardening or garden journalism, they are ever new and our age is rejuvenated and in the garden one becomes a youth again. Some of my friends who have only small or simple country cottage gardens are young at eighty years and over. I venture to think there is no other hobby on earth that is more adaptable to the conditions of every type of man, be he rich or poor, old or young, learned or simple.—JAMES PARKINSON.

WISLEY.

SIR,—It is possible to agree with part of your article on this subject without in any way adversely criticising the directorate.

As I understand it, Wisley is run by a committee. Now, the best work in any art cannot be done by a committee unless that committee is dominated by one personality, which is hardly likely to be the case with a committee of such ability as the R.H.S., and the result must be compromise.

When two or three great minds endeavour to co-operate on a subject in which they are intensely enthusiastic, the compromise cannot be so good as if each were acting independently. Taking your paragraphs:

(1) Everyone will agree with this; but the trouble is, as your leader of July 26th says, the definition of what is the most beautiful garden.

It seems to me, and to those with whom I sympathise, that a most beautiful garden must be one in which a complete and perfect "design" is worked out in its entirety and to the last detail.

If I may drag in another quotation, "From the nature of the ground in its original state—partly wooded, partly bare field—and from its having been brought into cultivation and some sort of shape before it was known where the house now upon it would exactly stand, the garden has less general unity of design than I should have wished" (preface to "Colour in the Flower Garden"). If this is the case with Munstead Wood, it is very much more so with Wisley.

The R.H.S. took over the garden in existence, by this means realising in a few years a result partly as good as would have been obtained in twenty, but not entirely. The garden had been laid out as a private garden with the anticipation of such expenditure as could be laid out on a hobby, and to convert that into a National Undertaking is a big job. They were handicapped also by the fact that the ground was a gift, and no radical or sweeping change could be made at once; neither did the finances of the Society at that time permit it.

A FINE CLUMP OF LILIUM GIGANTEUM.

What has been attempted can in some measure be gauged by the difference in the first buildings and the present building which house the laboratories and offices.

But there is another difficulty. Doubtless the majority of the committee are in sympathy with the trend of modern opinion in garden design, but there is a certain lingering of the old idea of the landscape gardeners that a garden is not to be treated as a garden but as a sort of imitation of some *natural* effect or effects.

There are at Wisley some herbaceous borders; they are replenished occasionally by stock from "trials," and their design, wriggling round a meadow terminated by one of the most awful "villas," leaves much to be hoped for. The arrangement of the plants is either accidental or the result of many opinions acting in discord.

I suggest scrapping the lot, laying the borders out long and square, double with grass or stone walks between, with yew hedges for boundaries, and bays in the grass for seats, with terminals, vistas and spaces for one or two really good pieces of sculpture. Then give each border, or pair of borders to one of the more eminent designers among the V.M.H.'s with the utmost liberty to design a border which, in colour and form, should be an example of British gardening: invite, if desired, contributions of the necessary plants from Fellows of the R.H.S.; and import, if need be, loam and calcareous soil—of peat and sand we have plenty.

We are at the moment particularly fortunate in possessing garden designers whose work is the envy of the world; but alas! there are few public gardens where it is to be seen, and a general invitation could not be admitted to private gardens so near London.

Wisley should, undoubtedly, be a place where gardeners can see what is the best plant of its kind and how to grow it.—H. FALKNER.

LILIUM GIGANTEUM.

SIR,—I am sending you a photograph of a clump of Lilium giganteum as nine bulbs flowered at once in the same clump, in case you would care to publish a reproduction in your paper. The photograph, of course, does not give one any idea how beautiful they were. They are grown in the home wood at Merton Hall, near Thetford, in Norfolk.—(Lady) ETHEL EDGAR.

GOOSEBERRY MILDEW.

SIR,—I notice in the answers to correspondents, July 19th issue, the advice given to burn the bushes. This disease no longer needs to be notified in Scotland, and if you cannot cure you can at least keep it in check. There are several methods which have been tried by the horticultural departments of the Scottish colleges of agriculture.

The first point to be observed is winter pruning; the points of all young shoots should be taken off and burned. You can see the mildew as a chocolate film on the young grey bark. Some people say spray with a caustic winter spray, others that this is useless. I am inclined to think dusting with a mixture of slaked lime and flowers of sulphur will do good, but will give it a further trial this winter.

Summer spraying with ½oz. of ammonium polysulphide does very well in some cases; but the fashionable summer spray is now sodium carbonate, 1lb. dissolved in 4 or 5 gallons of water and the spraying begun just after the fruit is formed; this is simple and no harm can be done with a weekly spraying, though other authorities think two or three times should be sufficient.

It allows the crop to be marketed as green gooseberries, as the white fungus, if washed off, does not hurt cooked fruit.

The trouble about replacing the bushes is that few nurseries have a stock of clean plants. I hope to try the effect of hot lime on the ground during winter; it cannot do any harm and may prove useful. But I was informed by one authority that it has never been proved that the fungus lives in the ground.

Is the disease known on chalk soil or where chalking is done regularly? Here the soil has very little lime in it and periodical dressings are needed to maintain the necessary lime content. Unless this is regularly done the soil becomes decidedly acid.—WILLIAM LOW, *Montrose*.

[The advice given to our correspondent was applicable to England, where our correspondent resides.—ED.]

SIMPLE GARDENING

PLANTING STRAWBERRIES.

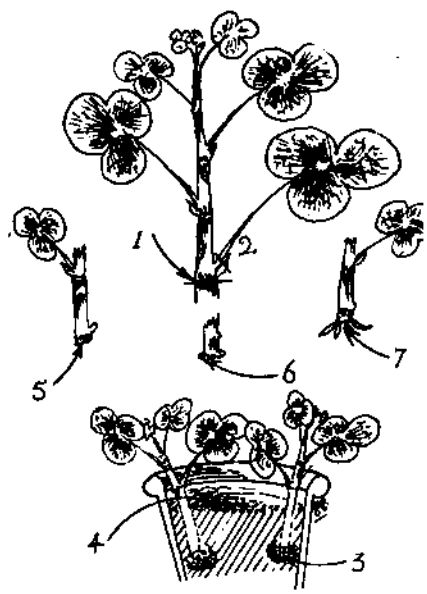
THE early planting out of strawberries results in the security of the plants against severe weather in the winter. This is a fact that applies in the case of heavy, as well as light, soils. In both instances numerous roots are produced throughout the autumn while the soil is warm. In naturally heavy ground a plant, possessing only a few roots, receives a severe check. In naturally light ground this early production of healthy roots helps the young plants to form plump crowns before the hard weather comes. A weakly plant in a sandy soil will not make up for valuable lost time in the spring. The soil, in every instance, should be very deeply dug or trenched, two spits deep. Soil already rich in humus—that which has been manured liberally with organic manures for the preceding crops—does not need any more prior to planting the strawberries, but all ordinary soils should be manured at this stage. After the strawberries are planted a surface dressing of basic slag, at the rate of 4oz. per square yard, will be very beneficial; it should be lightly pointed in and the whole work finished by adding a surface mulch of littery manure. In many gardens much space is wasted by planting too far apart. I like to plant in pairs 7ins. apart, 18ins. dividing each pair in the row and 20ins. from row to row. After the first year of cropping one plant of each pair may be discarded.

WHEN GRAPES ARE COLOURING.

When the berries reach the colouring stage they require different treatment from that necessary previously and up to this stage. The berries swell in three stages, first, directly fertilisation is complete; second, as soon as the stones have hardened, and lastly, when the colouring begins. The Black Hamburg and Foster's Seedling varieties are, approximately, eighteen days in the stone-hardening process; Alicante, Gros Colmar and Muscat of Alexandria with other late sorts, twenty-four days. While the stones are hardening there is no perceptible swelling of the berries, but directly the stones are hard the swelling begins. From the first appearance of colour in the berries twenty-four days should be allowed for the complete process in the case of early sorts and thirty days in the case of late ones, and, of the latter Alicante may be named as a variety in point. Before colouring commences, and especially while the stones are hardening, there is always a danger of the berries being scalded and, up to this stage, more atmospheric moisture is required with less ventilation. After colouring begins there is not much danger of scalding and less atmospheric moisture is required with more liberal ventilation. Ventilate judiciously through the front ventilators as well as through the top ones and, furthermore, a small opening at the top of the house through the night will be beneficial. Black grapes colour best and retain that dark blue-black appearance longer under a canopy of healthy leaves; the white varieties need sunshine and light to ensure that golden amber colour so much desired by every cultivator.

PROPAGATING SUMMER BEDDING PLANTS.

It is not possible to describe, in detail, the work connected with the propagation of all kinds of plants used for this purpose.



Only a few are referred to and these will be a guide to the methods necessary in striking others. Zonal pelargoniums, commonly called geraniums, are propagated as shown in the accompanying sketches. Short-jointed branches, not very sappy, are the best to select. This fact also applies to fuchsias, heliotrope, petunias, salvias and similar plants. Small cuttings, such as those of lobelia, are easily rooted in boxes; so, indeed, are all cuttings. The compost should be sandy and a cold frame used. No. 1, shows where to cut off the stem—through a joint; No. 2, leaf at that joint to be removed; No. 3, sand at the base of the cutting; No. 4, sand on the surface of the soil; No. 5, the base of the cutting when inserted; No. 6, the callus forming; No. 7, the roots beginning to grow. Careful watering is essential and shade in the case of tender cuttings.

CABBAGES AND ONIONS FOR SPRING.

The true value of these two crops can only be appreciated by cultivators after the passing of a severe winter. Even when crops, generally including, of course, the stored roots, are good or normal, the spring cabbage bed is very closely examined both by the owner and his neighbours. The present is a suitable time to make preparations for having such beds by sowing seeds of good varieties. Very early—July—sowings often result in the "bolting" of the plants; in the northern counties the latter part of July is not too early, but it is in the southern. But it is a fact that the strains now sold by our seedsmen are very pure and lessen the risk of "bolting" to a minimum. Now, I would urge readers to take a little trouble with the raising of the seedlings and their treatment during this autumn. The seeds should be sown in soil not previously cropped with these and similar plants, at least for several years past. The seeds should be sown thinly and the resultant plants transplanted before they become drawn. The ground for the final planting should be good, yet firm and well surfaced with old soot. Harbinger, Flower of Spring, Enfield Market and Wheeler's Imperial are typical varieties to grow. Of onions, Leviathan, Giant Rocca and White Mammoth are suitable.

OLD AND NEW LAWNS.

I am referring to the old lawns first because more work will be done on them, at this season, than on new ones. Where the soil was in good condition the grass has needed cutting every week throughout the summer, and that troublesome pest, moss, is already beginning to spread again. With the aid of a sharp-toothed iron rake all the moss possible should be removed and, twice weekly, afterwards the lawn should be vigorously brushed to help in the destruction of all bits that might grow again. Avoid rolling the lawn for several weeks as the firming of the ground tends to new growth of moss. The soil is warm now and new grass seeds will germinate rapidly and soon cover bare patches with young grasses. All that is necessary in preparing the ground, is vigorously to rake the surface, removing the roots of daisies and coarse weeds, and then sow the seeds thickly and evenly. Instead of raking them in, cover with a thin layer of sifted soil, roll and place a net on to prevent birds eating the seeds. New lawns may be obtained in the same way. The ground must be retained in a firm condition not dug deeply. The resultant young grasses should be cut once only this year—in early October, with a sharp scythe.

GEORGE GARNER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Brussels Sprouts.—In some gardens seeds are sown during the early part of the present month, with the object of securing an early supply of buttons next year. Sow the seeds thinly in lines 1ft. apart, and when the seedlings are large enough a portion should be pricked out in a nursery bed, the remainder being left undisturbed till the spring.

Cauliflowers.—Towards the end of the month a sowing of cauliflowers should be made, but to be safe I make three sowings: one at the middle of August, and then two more at fortnightly intervals. This is an important crop, because the cauliflowers are fit for the kitchen at a time when vegetables are none too plentiful. Select a sheltered spot, preferably an open sunny border which is well drained during the winter months. Thin sowing is essential, as strong sturdy plants are less liable to damp off through the winter months. When the plants are large enough, prick off a quantity in a cold frame, but the lights will only be required during frosty weather. Magnum Bonum and First Crop are both reliable.

Runner Beans.—During dry weather these are benefited by an occasional thorough soaking of water, and a spray overhead each evening. A light mulching of long manure is also beneficial. The pods should be picked directly they are ready; if allowed to remain the plants soon cease to be profitable.

VEGETABLES UNDER GLASS.

Cucumbers.—Where accommodation is available, and the requisite heat can be maintained, cucumber seeds may be sown to produce a winter supply. Keep the plants sturdy, free from mildew, and never allow them to become dry or pot-bound. In the meantime, collect the fermenting material, viz., manure and leaves, and when it has been turned several times it may be taken into the house and made into a hot-bed. Allow the rank heat to escape, and then place mounds of fibrous loam at intervals of 3ft. When the plants are put out, tie the growths to the wires, and frequently stop the young shoots. Plants in bearing should be assisted with liquid manure and a light top-dressing of soil. Avoid over-cropping, and cut the fruits before they begin to impoverish the plants. Mildew can be held in check by a sprinkling of sulphur; while the house or frame should be vaporised at intervals if white fly is present.

THE FLOWER GARDEN.

Antirrhinums.—These charming plants play an important part in the flower garden, and are fine both for beds and borders. Although they are often raised under glass in January, excellent results are obtained by sowing at the present time, when, moreover, they flower earlier. Sow the seeds thinly in lines 1ft. apart, and when the seedlings are large enough prick them out on a well drained border where they will pass the winter. In districts where this method has proved a failure, a cold frame will be necessary, but the lights will only be needed during severe weather.

Nymphæas.—To keep the pools clean and the plants healthy, all decaying leaves and old flowers should be removed about once each week. Weeds should also receive attention, and for small areas an iron rake or old birch broom will be found convenient for collecting them from the water. If black fly is present, a weak solution of insecticide should be sprayed over the leaves.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Peas.—The early kinds, Little Marvel and Pilot, have borne fairly good crops, but as each year passes one cannot fail to observe that the latter variety is pre-eminently the pea best suited—both as a first-early and as a cropper for Scottish gardens. As soon as the crops are over the pea straws should be cleared away and burned.

THE FLOWER GARDEN.

Centaurea candidissima.—This somewhat old-fashioned plant is very useful for bedding purposes, especially if anyone still goes in for the ribbon border style of bedding, as its silvery white foliage shows up with marked effect, even intermixed with begonias or brown calceolarias in beds it is quite suitable. To obtain plants for next year, seed should be sown now in a box filled with a medium fine soil. When the seedlings are large enough to handle, they should be potted singly into 3in. pots and wintered in a peach-house or other structure from which frost can be excluded.

Chrysanthemums.—These plants should be looked over and kept well tied to the stakes, as winds and heavy rains are liable to damage them.

Cuttings.—If reserve stock has not been kept from which to procure cuttings, every opportunity should be taken from now onwards to secure a few from such bedding plants as alyssum, lobelia and nasturtiums.

Roses.—The climbing varieties have as usual grown well and produced many long and vigorous new stems, these require to be occasionally tied in to prevent them from being broken and blown about.

Sweet Williams.—Seedlings should be set out about 6ins. distant from each other in lines 1ft. apart. Those who are fortunate enough to possess the old dark crimson double-flowered sweet william should secure cuttings now and insert them in sandy soil in a cold frame. Seedlings of double daisies should be set out at similar distances. Seedling foxgloves should also be set out and if one has ground to spare they should be allowed a distance of 9ins. from plant to plant in the lines.

THE HARDY FRUIT GARDEN.

Wall Trees.—Apricot, pear and plum and indeed all fruit trees growing against walls should be copiously supplied with water—and occasionally with liquid manure—at the roots.

FRUITS UNDER GLASS.

Melons.—The pleasant aroma in the melon house is a good indication that the fruits are near the ripening stage. The cultural conditions therefore should be somewhat changed, the ventilators being left open night and day, and the damping of stages and pathways discontinued, while the roots should only receive sufficient water to keep the plants in a turgid condition. Each fruit should part readily from the stem when ready for use.

Peaches.—As soon as the fruits are cleared from the intermediate house, resume the syringing of the trees, and make sure that the borders are sufficiently moist, as at no time should peach and nectarine roots suffer for want of water. If red spider gained a footing during the ripening period of the fruits, the trees should be well sprayed with Abol. The strength to use is indicated on each tin—but if ½oz. of nicotine is added to each gallon the insecticide will prove more effectual.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Veltheimia viridifolia.—Where stocks of this plant exist, the bulbs should now be started into growth. If in bad condition at the root, they should be shaken out and re-potted in fresh compost. Single bulbs will do quite well in 5in. pots. By allowing the bulbs to increase without dividing them, fine large specimens in 7in. or 8in. pots may be obtained, and when well flowered are very handsome. Such specimens, if in good health, will often go for several years without re-potting. Dry bulbs can generally be purchased at this time; a stock can also be raised from seed, and if well grown should flower the third year from seed sowing. This plant, with its reddish spotted lachenalia-like flowers, although not showy, has a certain charm which always appeals to lovers of choice plants. V. glauca, with beautiful glaucous undulated leaves, is also worth growing. They are both natives of South Africa and, like most South African bulbous plants, only require a cold frame or a cool greenhouse. Newly re-potted plants should be given very little water at the root until they have made a quantity of fresh roots.

Aristea corymbosa.—This beautiful blue-flowered plant is a native of South Africa, and although it belongs to the iris family it has a hard woody stem, with fan-shaped clusters of leaves. It is by no means an easy plant to propagate, but may be increased by means of cuttings inserted in pots of sandy peat some time during August. The cuttings should be detached with a little of the woody stem attached to the base. The cutting pots should be stood under a bell-glass in a cool greenhouse and the plants given the same treatment as greenhouse heaths.

Cyclamen seed for flowering next year should now be sown thinly in pots or pans, using a fairly light compost for this purpose. The seed pots should be stood in a house with an intermediate temperature, and, after watering, a piece of glass should be placed over the pots, keeping them shaded until germination takes place. As the latter is generally somewhat irregular, the most forward plants should be carefully taken out, without unduly disturbing the remaining plants or seed. For this reason, also, thin sowing as already advised is very important. The young seedlings should be pricked off into pans or pots, according to the quantity required, using a light rich compost, to which some old mortar rubble may with advantage be added. They should be wintered in an intermediate house, keeping them well up to the roof glass. If forward enough, they may be, in late autumn, potted on singly into thumb pots. Cyclamens which are well established in their flowering pots will now benefit by frequent applications of dilute liquid manure and soot water; a good guano is also a safe and good all-round fertiliser. Later batches as they require it should be placed in their flowering pots; 5in. pots being of suitable size.

Freesias should be potted up this month, as early potting is very essential for success. As they are free-rooting plants, a good compost should be used; this may consist of 3 parts good mellow loam, with the addition of some leaf-soil or old mushroom-bed manure. Five or six inch pots should be used, placing twelve to fifteen corms in a pot. The pots should be stood in a cool frame and kept shaded until growth appears. They should not be covered with ashes, as is sometimes advised, although they may be plunged to the rim in ashes or fibre. Cool treatment with plenty of light and air is very important.

Royal Botanic Gardens, Kew. J. COUTTS.

Digitized by Google

ANSWERS TO CORRESPONDENTS

THE FLOWER GARDEN.

Verbena venosa (K. E. T., Warwick).—The roots of this beautiful verbena are perennial, but they so frequently succumb to the wet and changeable weather during our winters it is usual to treat the plant as an annual, seeds being readily obtained. Sow the seeds in a heated greenhouse during the second half of February or early in March. Another method is to lift and store the roots in a frost-proof frame, keeping the soil just sufficiently damp to prevent the roots shrivelling.

Pink-coloured Flowers for a Border (J. M.).—The following kinds and varieties of flowers would fill the gap referred to by our correspondent: Anemone japonica, A. rubra; Aster Lil Fardell; Chrysanthemum James Bateman, C. Kitty; Phlox conspicua; pink antirrhinums, including the variety Nelrose; Phlox Clara Benz; P. Meteor and P. Selma, with Antirrhinum Nelrose, would make fine effective groups, alternating with the blue flowers in the border. The anchusa thrives in a deep loam in a sunny position. It would be advisable to surround the roots in winter with old dry ashes. Also, the boards may be used. Grow Malva moschata.

Water Lily Pond (E. E. S.).—If our correspondent is able to move the tubs, transfer them under the dense shade of trees where they can be frequently saturated with water. Wet leaves would be useful round the tubs, providing they did not heat. Assuming that it is not possible to move the plants, pack wet tiffany or cloth round the tubs and during the day cover the tops of the plants with tiffany or frigidoma. Place short thick stakes standing perhaps 1ft. or more from the soil to prevent the covering crushing the leaves and flowers unduly. Drench the covering several times daily with water. Remove the covering at night and during rain if of some hours' duration.

Violas Dying (D. H.).—The soil in which the violas are growing is very sour and would be much improved if a dressing of lime, at the rate of 6 oz. per square yard, was applied in the autumn, not for violas only, but also for general crops. The plants of violas have perished through a root fungus which has been much favoured by the present condition of the soil. Treat the latter as advised above.

Plants to Flower with Delphiniums (Mrs. R. T. P.).—The following kinds of plants will be found suitable for such borders. All the plants, whether raised from seeds sown this summer or from the division of roots, will need planting during the autumn: Canterbury bells, Centaurea montana, columbines, flag iris, hemerocallis, lilies, peonias, pentstemons, pinks, antirrhinums (especially A. Nelrose), Oriental poppies, pyrethrums, sweet peas (the latter sown in the autumn), carnations, cornflowers, campanulas, gladioli (the corms of these being planted in March) and montbretias.

Failure of English Irises (E. S. C.).—It is difficult to account for the failure of our correspondent's English irises. The failure this year might be accounted for by the exceptional time they took before they flowered, owing to the cold spring, so that the flowers came out when the foliage had begun to turn colour and they in turn were affected. The failure of the roots points to something in the soil eating them, or to there being something in it which poisons them. The manure our correspondent dug in might have been good for nothing, hence the poverty of the soil would still remain. Plant them in fresh ground another year.

Nelumbiums (W. R. J.).—If our correspondent employs large tubs for these liquid or artificial manure should be liberally used. Nelumbiums are really suitable for large ponds, as the rhizomes may run 30ft. or 40ft. in a year. The lotus, is such a gross feeder, that, sometimes, when grown in tubs the plants are starved into rest at an early date and the leaves turn a sickly yellow and present a sorry appearance. An excellent method of growing them under artificial conditions is to excavate a hole 5ft. or 6ft. in diameter and 2½ft. deep, with slightly sloping sides. A form should be placed inside the excavation, leaving about 4ins. clear for concrete. This makes an ideal pool for either nelumbiums or water lilies, being both water-tight and frost-proof.

Peonies Not Satisfactory (W. B.).—The specimen shoots sent for examination show more clearly than ever that frosts injured the young shoots, and also that the plants are not making healthy roots in the soil. The latter is deficient in nutriment for these plants. It would be advisable to prepare another site and transfer all the healthy plants to it. Peonies have not many insect enemies, and the grubs enclosed are not the cause of the trouble, but the condition of the plants attracted them. The tiny maggots are of the species cecidomyia, generally found in grasses.

Standard Heliotropes (Miss G. P.-D.)—Probably the specimens now being cultivated are too old and stunted through the roots being confined in such small pots. It is advisable to propagate young plants every year, to grow the single stem to the required height, then stop to encourage branching. Stake at an early stage of growth. Re-pot as required to avoid stunted growth. The old specimens should be re-potted into larger pots, not reduced to enable re-potting into smaller ones. Use a good compost. Winter in a greenhouse temperature and water sufficiently to keep growth just active throughout the winter.

Bulbs (J. W. B.).—Impossible to say definitely what the bulbs are, but they are probably some scilla species. Without knowing where they come from, one cannot tell whether they are hardy or not.

TREES AND SHRUBS.

Grubbing Thorn Bushes (C. E. C.).—Steam tractors are used to haul out trees by the roots. Whether this method would be as cheap in our correspondent's case as grubbing them out by hand will depend largely on local circumstances. The best way will be to consult a local timber merchant or tractor contractor, and get a rough estimate of the cost. Compare this with the probable cost of grubbing by hand. Unless the area is a large one, we should recommend the latter method, as it would certainly be more efficient, if there is not much difference in the estimated cost.

Dodonæa viscosa (Mrs. H. J. E.).—This plant grows up to about 20ft. It is a slow-growing shrub, native in New Zealand. The leaves are narrow, 1in. to 3ins. long, and pale green. It prefers a coastal position and is very suitable for seaside planting. In cultivation it enjoys a medium soil, and should be propagated by means of seeds.

Dwarf Conifers from Cuttings (C. C. M.)—The average cuttings made of short twiggy growths will be from 1in. to 2ins. long with a thin "heel" of the previous year's wood attached at the base. Insert the cuttings during August or September in pots containing sandy soil, cover with bell-glasses, and stand them in a cold frame or cool greenhouse and shade from sun. When a large number of cuttings are to be rooted, make up a bed of sandy soil in a sheltered shady spot outside, and insert the cuttings in groups according to the size of the hand-lights or cloches that are to cover them.

Plagianthus Lyallii (A. C. B.).—This beautiful New Zealand shrub seems more subject than most exotics to the sudden collapse of a twig or branch; sometimes even the whole bush withers. In the first place, it is not absolutely hardy, and, growing in unfamiliar conditions, is more liable to disease. The least damage to the bark from chafing by the wind we have known to start the coral spot disease. In another case, a plant growing against a west wall lost one of its largest branches through injury where fastened to the wall for support. There is no difficulty in layering the branches successfully, but rooting takes two years. A fair percentage of cuttings made of the half-ripe wood during late summer should root in sand in a close propagating case.

Specimen Tree for Grass Path (W.E.N.)—For such a position one of the double Japanese cherries would be very suitable. The trees are comparatively slow in growth and very free flowering. The blooms are more lasting in beauty than the single-flowered fruiting cherry. The latter would also soon outgrow the position. The variety Hizakura, with double deep rose blossoms, is one of the best sorts.

THE ROCK GARDEN.

Silvery-leaved Rock and Border Plants (Mrs. W., Berkhamsted).—Acantholimon androsaceum; Achillea argentea, A. ageratifolia, A. Kellereri, A. Wilczekii, A. umbellata; Alchemilla alpina; Alyssum argenteum; Anaphalis margaritacea, A. cinnomomea; Androsace lanuginosa, A. sarmentosa; Antennaria dioica; Anthemis Biebersteiniana, A. montana; Anthyllis montana; Artemisia lanata, A. Baumgartenii, A. pedemontana, A. vallesiaca, A. sericea, A. Mutellina, A. Stelleriana; Asperula arcadiensis; Aster sericeus; Carlina acanthifolia; Centaurea dealbata; Cerastium Biebersteinii, C. tomentosum; Chrysanthemum Aucherianum, C. deustum; Convolvulus althæoides, C. incanus, C. spithamæus; Dianthus cæsius, D. plumarius; Eriogonum racemosum; Erodium chrysanthum, E. amanum, E. supracanum; Geranium argenteum, G. cinereum; Helichrysum plicatum, H. angustifolium, H. Stœchas; Hieracium villosum, H. gymnocephalum, H. pannosum; Iris fœtidissima variegata; Leontopodium alpinum; Lithospermum canescens; Marrubium sericeum; Omphalodes Luciliæ; Veronica telephioides; Onosma albo-roseum, O. Bourgæi; Origanum Dictamnus; Othonnopsis cheirifolia; Oxalis enneaphylla, O. adenophylla; Paronychia argentea; Potentilla argentea, P. Anserina, P. argyrophylla, P. nitida, P. speciosa; Ranunculus amplexicaulis; Salix lanata; Scabiosa Pterocephala; Sedum dasyphyllum, S. Ewersii, S. roseum; Sempervivum arachnoideum; Stachys lanata; Teucrium Polium, T. montanum; Veronica incana; Wahlenbergia Pumilio; Saxifraga lantoscana, S. Aizoon, S. Cotyledon, S. Burseriana, S. cochlearis, S. longifolia; Romneya Coulteri; Veronica pinguifolia.

THE GREENHOUSE.

Plants to Grow in a Small House in Winter (A. K. M.).—Sweet peas would do well for furnishing the back wall in spring. the seeds should be sown in small pots late in September, two seeds in a pot. The young plants may be kept in a cold frame till January, then shifted to the large pots. Flowers will open about May 5th. Scillas.

Digitized by Google

crocuses and irises would answer for the box. The Spanish iris would flower early in spring. Pot early and use for all a good porous soil. A few winter-flowering wallflowers would be useful; procure young plants now, pot or box them, retain outside till November, then place under glass. The faded leaves only of hollyhocks should be cleared away after flowering, and any loose surface soil, then place 1 peck of dry ashes round each plant close up to base of leaves. Set traps to catch the mice.

THE ROSE GARDEN.

Leaf-curl in Roses (Miss N.).—As regards the curl on the leaf of the rose specimen sent, it appears to be due to the ravages of caterpillars. We should suggest that spraying should be carried out throughout the summer. A paraffin and sulphur lotion might be found useful in this case, or even Bordeaux mixture. If the attack is limited, hand-picking of the leaves might be resorted to. Soapy or sooty water might also quite well be applied.

MISCELLANEOUS.

Various Questions (M. M. B.).—The only effective way to get rid of the nettle roots is to dig them out—every bit that can be found. If our correspondent wishes to have the bank covered with a carpet of foliage simply, then plant Cerastium tomentosum. A good glaucous grass is Elymus arenarius. Funkias would also succeed. Bamboos thrive best on the banks of streams; they like moisture, but not stagnant conditions. The plants would do well near the stream—about 2ft. above water level. Spiræas should also be tried. Trout would be the best fish to place in the stream, but neither these nor any other fish would live if the stream nearly dried up at times. The Madonna lily does not like disturbance in the soil, nor its bulbs being planted deeply; ordinary garden loam is suitable. Pears may be tried on the bank, but the soil should be well trenched and prepared.

Gas Lime (D. C.).—If our correspondent is not able to procure gas-lime, the soil should be sterilised with a solution of formalin. One pound of formalin to 12 gallons of water and apply at the rate of 1 gallon to 2 square yds. of ground. If applied forthwith, leave the ground uncropped for two months—till the end of September.

Names of Plants.—(H. F.).—Cistus cyprius.——(W. L. T.).—1, Genista tinctoria; 2, Campanula pusilla; 3, C. p. alba; 4, Veronica orientalis; 5, Sedum reflexum. ——(A. G. P.).—Teucrium fruticans.——(Col. J. H. H.).—1, Lysimachia vulgaris; 2, Ilex Aquifolium ferox.

POTTING NERINES

OUR first advice upon this subject is never to re-pot at all if it can possibly be avoided, but a time comes when this must be done and a similar necessity arises when new bulbs are procured. In both cases, the period when this is done is of vital importance and the best time is when they are at their most dormant stage and just *before* new root and foliage growth commences. This is during August and no time should be lost in dealing with the whole of the plants that need this attention.

Second only in importance to the date of potting comes the soil and this should consist of strong, rich loam, to which a generous addition of coarse silver sand has been made, with a very moderate amount of leaf-mould. In no case must the pots be large, the 4½in. being sufficient for a single bulb, while three may go to the 6in. New bulbs should be potted as soon as possible after receipt and a great point about the new hybrids is that—if culture is correct—they will flower annually. Flowering takes place during September and October and the flowers are remarkable for the extended period over which they remain in good condition.

Synonymous with flowering is the production of the leaf growth and, all through the winter, the soil should be kept evenly moist and the plants in a good light as near as possible to the glass. Do not water until new growth does appear and remember that old established bulbs, that have been in the pots for three or four years, must be freely fed all through the growing season with liquid manure, continuing this until May when the foliage begins to fade. After this time, gradually reduce the supplies until the plants are completely at rest and then place on a shelf as close to the glass as it is possible to get them and allow to bake quite unshaded, until flowering time returns. Regular flowering is entirely a question of winter growth and this summer baking; therefore success cannot be achieved where due attention is not paid to these important items.

When potting, it is not at all necessary to split up the clumps of bulbs into single examples, for the whole mass can be transferred to a slightly larger pot and filled in all round with new soil. Pick away a little of the old soil and do not give too large a new pot or you may check flowering. Make the soil quite firm and do not water until new growth begins.

Nerines seed very freely when hand fertilised and raising seedlings is most fascinating work, especially where one has several varieties and some cross fertilising has been done. Seedlings are quite easy to raise, especially if they are sown immediately the seed is ripe, and by careful culture, flowering plants may be secured in three years. BULBIST.

TRADE NOTE

A NEW LABEL.

We have received from Messrs. W. Darlington and Sons, Limited, London Fields Station, Hackney, E.8, a new label for the nurseryman. In appearance it is just like the ordinary tie-on label as used by nurserymen, but it is claimed that this new label resists the action of rain and sun and that it is waterproof through and through. If this label lives up to its reputation it should prove a boon to both nurserymen and their customers.

Wisley Trials.—The following awards have been made to Currants by the Council of the Royal Horticultural Society, after trial at Wisley: Award of merit—Florence (black), sent by Sir Charles Nall-Cain; Invincible, Giant Prolific (black), sent by Messrs. Storrie and Storrie, Glencarse, Perthshire; "Big Red Dutch" (red), sent by Messrs. B. Ruys, Dedemsvaart, Holland. Highly commended: Orr's Seedling (black) sent by Mr. William Orr, Carnforth; Long Bunch White (white), sent by Messrs. B. Ruys, Dedemsvaart, Holland.

The Glasgow Show.—Present indications point to the forthcoming Horticultural Show in the Kelvin Hall, Glasgow, from September 2nd to 5th next, being one of the most popular and attractive ever held in Scotland. The Show will again be run under the joint auspices of the Glasgow Corporation and the Glasgow and West of Scotland Horticultural Society and apart from numerous cups, trophies and medals, a sum of £1,500 will be awarded in prizes. Substitutes for stone for rock gardens will be allowed, while water will be supplied if desired. Cut flowers of aquatic plants may be used. There are over 400 classes in all in the Schedule of Prizes. Entries close on August 23rd. A large space in the hall has been reserved for trade exhibits and already a good amount of this has been booked. Applications by firms for space should be made to Mr. C. P. Hainsworth, General Manager, The Kelvin Hall, Glasgow. The Show will be opened by Her Royal Highness the Duchess of York.

A Show for Amateurs in London, 1925.—The Council of the Royal Horticultural Society is making arrangements for holding, on June 30th, 1925, in the Royal Horticultural Society's Hall in Vincent Square, Westminster, S.W.1, a special show for amateur growers. Special classes for cut roses, delphiniums, sweet peas, gladioli, carnations, hardy pinks, herbaceous plants and violas will be included. There will also be classes for greenhouse plants in pots, orchids and ferns. Amateur exhibits from all over the United Kingdom will be welcomed and the classes will be arranged to suit the owners of small as well as of large gardens. Schedules giving full information concerning this show are now in preparation and, in a few weeks' time, will be obtainable on application to the Secretary, Royal Horticultural Society, Vincent Square, Westminster, S.W.1.

A Useful Invention.—We have received from Mr. C. J. Beckett of Fulbourne, Cambridge, a very useful appliance which he has invented. It will enable a gardener to attach an ordinary pair of pruning shears to a light pole, broom or hoe handle and cut off shoots from bushes and trees many feet higher than he can reach by hand. Practically every cultivator who has pruning to do will find the tool a boon. The action is somewhat similar to that of the "Tree-pruner," as two plates are screwed together to hold tightly one handle of the pair of pruners, instead of a socket; pruners of various sizes and forms may be fitted. The other handle of the pruner is worked by a long wire to which is fastened a wooden handle. There is a slight weakness here as neither the wire nor the wooden handle is strong enough to enable the operator to lever the handle of the shears with ease when engaged in cutting off matured shoots. But this weakness can be remedied by the operator himself, if found to be a defect, by attaching a stronger wire and handle, respectively.

A CORRECTION.

In our issue of August 2nd, by an unfortunate typographical error, the wrong titles were given to the illustrations of the article on "Hardy British Ferns," by Mr. W. Logan. The correct titles are: On page 532, "Polystichum a. d. p. densum robustum Perry"; on page 533, top, "P. a. d. plumosum densum Perry's No. 4; bottom, "Scolopendrium v. crispum plumosum Perry." We much regret this mistake.

THE COTTAGE WITH ITS YELLOW ATTENDANTS, AT GRAVETYE MANOR.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

OUR BULB NUMBER

I APPROACH this Editorial with considerable misgiving; as it is a Bulb Number, I ought to write upon bulbs, and I know little about the intricacies of these fascinating plants. I feel like the journalist who has to prepare a Christmas number with the temperature over 70°. I had my chance the other day during the hailstorm to write a most cheering article upon how bulbs with snow above them are only waiting for the first fine day to spring into growth, but, like so many real chances, this one was missed, and now I have to think ahead and imagine bulbs being planted, bulbs lying dormant underground, bulbs pushing their noses through the soil, and bulbs in their first burst of flower after many weary months of waiting. After all, they are worth waiting for. What could be more beautiful than a meadow filled with the first daffodils swaying in the wind and dancing because Spring is approaching; or a bed of sturdy tulips on a May evening; or all the hundred and one charming plants which are included in the word "Bulb"?

I have read all the articles in this issue as an ordinary reader, a most gratifying sensation, and have found them intensely interesting and useful upon the subject of bulbs. And now—well, if I write a dissertation upon bulbs, I lay myself open to attack from every side, and I am very vulnerable on the bulbous question; so let me approach the subject from another angle, that of bulb catalogues and of the people who buy bulbs. Here I feel myself upon surer ground, for bulb catalogues are always interesting and many of them are full of information unobtainable elsewhere. I have not seen the 1924–25 series of catalogues, but there is little doubt that they will be equal to, if not better than, the previous high standard which most firms have attained. Probably in bulbs more than in anything else there is a distinct cleavage between layman and specialist; the layman buys his bulbs in bulk, and as long as what he buys as a daffodil comes up as a daffodil he is satisfied; but the specialist examines every point down to the minutest detail: there is no specialist like him, and specialist in this case is synonymous with enthusiast.

I am very much of the layman. I am agreeably interested to hear that a Poetaz Narcissus is the result of a marriage between Poeticus and Tazetta; they have such charming names; but I am little the wiser. In bulb time at Vincent Square I have to tread very warily. When I get into difficulties I enquire discreetly of some kind-looking specialist for information and then claim it as my own with as bold a face as possible.

However, this is all by the way; it is only to show how very ignorant even a gardener can be in some branch of this gigantic subject. Some complaints have reached me that bulb catalogues are too obviously written for the specialist; but it must be remembered that the bulb merchant has to satisfy everybody. He has no idea to which category you belong, and, after all, you may go to bed a layman and, being sleepless for an hour or so, read from cover to cover Mr. Jacob's new book on "Hardy Bulbs for the Amateur," which *Country Life* is bringing out, and so wake up in the morning a budding specialist. Such things often happen, and it is for such as these that those who sell bulbs have to cater. Is there not a proverb about the early bird? Most catalogues mention collections of unnamed bulbs sold at a fixed sum, and these are for the layman. He may not buy individual varieties, but at least he can read, mark, learn and inwardly digest.

At least, I have learned one valuable lesson regarding bulbs, and that is, "First come, first served." Buy your bulbs early, and have in your mind's eye the exact position where the bulbs are to be planted. Plant at the correct season, and then you can hibernate until the first one arrives at flowering stage. After walking gingerly around the subject I can say no more. THE GARDEN hopes that the next bulb season will be a successful one, be you a layman or a specialist: I am sure it will be after reading the words of wisdom in the following pages.

THE CULTIVATION OF FLOWERING BULBS

BY J. DUNCAN PEARSON.

THE Editor has asked me to write a few notes for amateurs on the growing of bulbs. This I will do to the best of my ability, but would preface the instruction by saying that no information that I or any other writer can give will be of much service unless the amateur will make full use of his own observation, and be ready to turn even failures into good account for future guidance. A writer on photography once said, "let all your chemicals be mixed with common sense." This remark might equally well be applied to gardening, for if gardeners merely follow the advice of writers on gardening, without considering the weather, condition of soil, or their own particular position of latitude, they are certain to go wrong sooner or later.

In trying to give advice about growing bulbs one is faced with a difficulty, namely the greater number of amateurs do not want to *grow* bulbs, but only to flower them successfully.

HERALDS OF SPRING THROUGHOUT MEADOWS AND WOODLAND ALIKE.

For instance, they have a nice bed of hyacinths or tulips, but cannot afford to leave these undisturbed until they ripen off, as the bed will be required for summer bedding of some kind. Trade growers on the other hand make the *bulb* of first importance, the bloom a rather secondary matter. Bulbs lifted before they have gone to rest will never equal properly ripened ones, but if lifted when out of flower and laid in the soil in trenches they will generally make fairly good bulbs for the next season—if not good enough for bedding they often come in very useful for cut flowers if planted in the kitchen garden.

HYACINTHS.—To secure the best results the bed should be well dug, and roughly raked, then place the bulbs in position (about 6ins. apart) and plant with a trowel, taking care to put them at an even depth of 5½ins. (4ins. of soil above the bulb). Then rake again to make tidy. If severe weather sets in during the winter a light dressing of short stable manure may be applied with advantage; it will protect the bulbs and give them a little extra "push" when the flowering time comes round. Hyacinths require such very special cultivation that one must not expect much from them a second year, but they are worth keeping for odd corners of the garden.

TULIPS.—Same preparation as for hyacinths, but dig in some bone flour when planting, and if the soil be poor give a dressing of stable manure during the winter. Tulips are rather greedy feeders and like rich soil, but it is never wise to dig in fresh manure with any bulbous subject. If the bulbs can be left until the foliage has turned yellow or brown, they should then be lifted and stored in shallow boxes in a rather warm room or shed, but not exposed to the sun. On some soils tulips may be left in the ground for two or three years, but in nine cases out of ten the artificial ripening is of much benefit. If the beds must be cleared before the bulbs have gone to rest, lift them and lay them in as mentioned at the beginning of this article; taking them up when tops are dead and replanting them in October or November. October is the better time as the soil is more likely to be in good condition than it may be later on. The bedding varieties of tulips are most suitable for mass bedding. Darwin and other May-flowering kinds are more suitable for dotting between other spring flowers, such as myosotis, arabis, etc., or for planting in clumps in the herbaceous border. Plant 4ins. or 5ins. deep and 5ins. apart.

CROCUSES.—These are very hardy bulbs and no particular preparation is really necessary. They may be planted nearly any time between September and December; cover with 2ins. of soil and place them about 3ins. apart. Crocuses look their best when dotted about among low-growing perennial plants, the green of the perennials setting off their vivid colo urs to advantage. They may also be planted as edgings to taller-growing bulbs, or in bold clumps; but I strongly advise the first style of planting.

BULBOUS IRISES.—These include the English Iris, the Spanish, the Dutch, and the little gem Iris reticulata. All these should be planted earlier than most bulbs, about mid-September is a good time. English iris will succeed best on rather stiff, cool soil, the others require a lighter soil to be seen at their best. Reticulata is a very early-flowering species and is very particular about its soil, so it would be wise to try only a few to see if they will be happy in your garden; more can be

Digitized by Google

added if found to do well. The Spanish are so cheap that they are worth planting every year even if they do not thrive a second season. Plant about 3ins. deep, reticulata and Dutch should be 2½ins. deep and about 3ins. apart, the English being more robust growers may be a little deeper and rather farther apart. These bulbous irises will generally last a year or two without being lifted; a light dressing of stable manure put on the bed in the autumn is beneficial.

DAFFODILS.—These are my prime favourites and I could write pages about them, but the Editor has limited me to a certain space so I must refrain! These plants hate fresh manure, and some of the species cannot stand a trace of it in the soil. However, the bulk of the hybrids in general cultivation do best on fairly good land. The best preparation is to manure the land for a previous crop, then let the daffodils follow after well digging up and airing the soil. The only safe manure I can advise at planting time is bone meal, about 3oz. per square yard—not more—also a dusting of wood ashes when the growth is pushing through is good. I have tried many other manures but never found them of any service. Plant in September, about 2½ins. of soil above the bulb where soil is stiff, deeper on sandy land. They may be planted in rows in beds, in clumps in the flower border, or in the grass. Nowhere do they look better than in the grass, but they must be planted in artistic groups to give the best effect. Let the intending planter study some well arranged groups already in position, it will teach more than pages of writing would do. I would advise the amateur to leave his daffodils undisturbed for two or three years—if they seem to be doing fairly well. At the end of that time they will need a change, for if doing well they will need dividing, and if not doing well they will benefit from a change. The bulbs should be lifted as the foliage turns yellow, taking the Poeticus section first, the Incomps. second and trumpet varieties last. As a rough guide I may say that here in the Midlands we begin lifting about the last week in June or first week in July.

ANEMONES, SNOWDROPS, SCILLAS, CHIONODOXAS AND MUSCARI are all useful plants for the garden. They may all be planted to remain for some years. Slugs are great enemies to anemones and will eat them off as fast as they grow if not attended to.

CHIONODOXAS, CLOSE ALLIES OF THE WILD HYACINTH.

GLADIOLI.—Both early and late sections are useful for the garden and for cutting. Of the early varieties Colvilei alba, The Bride, Blushing Bride and Peach Blossom are some of the best, and of the three The Bride is the strongest grower and freest to flower. The early gladioli flower in June and July. Plant in October or November 3ins. deep and about same distance apart.

The late section contains some gorgeous flowers, some of which attain a great size. They should be planted in April in well prepared soil. In mild winters they may be left in the ground, but from my experience I would advise that they be lifted when the tops turn yellow—about end of October—and stored in a frost-proof shed until the following April. Plant 3ins. or 4ins. deep and 6ins. apart.

LILIES are beautiful in the garden when well grown, but are not very easy to manage. Nothing is more important for this family of plants than shelter; if they can be placed in front of low-growing shrubs, or rhododendrons, azaleas, etc., they will succeed far better than if planted in the open garden. It is not shade they require so much as shelter from the wind. Lily bulbs should never be allowed to get really dry, so if received when the ground is unfit for planting, bury the bulbs in some fine soil quite 4ins. deep and keep out-of-doors exposed to all weathers rather than store them inside, then put them in the ground when it is fit for working. I think I have used up all the space allotted to me and hope that the brief notes on the various bulbous plants will be of benefit to some of the many readers of THE GARDEN.

CROCUSES IN A WOODLAND SETTING.

BULBS TO BUY

THE FOLLOWING NOTES SHOULD SERVE AS A GUIDE TO THOSE WHO ARE IN DOUBT AS TO WHAT BULBS TO SELECT FOR FLOWERING IN THEIR GARDEN NEXT SPRING.

FOR several reasons, ordinary people with ordinary gardens must find it extremely difficult to know what to buy in the way of fresh varieties when the time comes round for them to send their requirements to the bulb dealer. They see, comparatively speaking, little that is new in their neighbours' gardens, and they have no opportunity of visiting large shows where the newer varieties are displayed. Perhaps, too, last year or the year before, some did take their courage into their hands and bought some unknowns, but those unknowns did not turn out the success that was anticipated, and when the time for ordering comes round again—what then? The catastrophe is too recent to be forgotten. "Once bitten, twice shy," "No more dark horses," "Old friends are best"—sentiments like these are very near the surface when the next order is made out. The result is, "I had better stick to what I have had before." This, of course, is very likely the wise and only thing to do under certain circumstances: as when, outside, a colour scheme has to be considered, or when, indoors, the drawing-room is all in all; but in an ordinary way among ordinary people who have ordinary gardens I would suggest that a trial be given every year to one or two novelties—something, that

A FINE BED OF HYACINTH GRAND MAITRE.

SCILLA HISPANICA IN AN IDEAL POSITION.

is to say, which they have never grown before. This means that my lists must contain at least a small proportion of things which are somewhat out of the common. Again, one never should take too much for granted. That it is never too late to learn, was once brought before me in a very striking way. I was talking tulips with a friend in the old Horticultural Club Room at the Hotel Windsor, and had just finished extolling to the skies that great early variety, Prince of Austria. It was in the small room on the ground floor, and Mr. William Marshall was sitting close to us. Presently he said to me, "What was that variety you were just now praising—Prince of Austria? I don't seem to know it. I will get some this autumn and try it." That this "grand old man," who had been Chairman of the Floral Committee of the Royal Horticultural Society for so many years, did not know such a famous and well known early tulip as Prince of Austria made as deep an impression on me as the vision of the sheet full of all manner of living creatures did upon Peter. I learnt the lesson that I must never consider any variety to be too well known to be mentioned. There may be someone who may be glad to know about it. Hence, no variety is too common to be excluded. This production of mine is intended to be a sort of horticultural cocktail made of bulbs. I hope I have so blended the contents that I have made a good one.

Here, then, follow my lists:

ALLIUM.

sphærocephalum. (Try a clump.)

ANEMONE.

The St. Bavo strain. Flowers from mid-March to mid-May. So bright and jolly. St. Brigid. Giant French.

CAMASSIA.

So easy to grow, so distinct, and so uncommon.

Cusickii (lavender) — esculenta Royal Purple (deep blue)
esculenta (rich blue)

CHIONODOXA (GLORY OF THE SNOW).

Luciliæ (blue with white centre) — sardensis (gentian-blue self)

CROCUS (SPECIES).

If these are strangers, try a few early-flowering ones, then next year speciosus and zonatus, which bloom in autumn.

Imperati (heliotrope and fawn) — Sieberi (mauve)
susianus (yellow) — Tomasinianus (lavender)
versicolor (white)

CROCUS (DUTCH VARIETIES).

Hero (dark purple) — May (white)
Maximilian or Dorothea (silvery mauve) — purpurea grandiflora (purple

ERYTHRONIUM.

American varieties which want shade and damp but well drained soil. Try them.

grandiflorum (yellow) — Hartwegi (buff)
Johnsoni (rose-pink)

GRAPE HYACINTH (MUSCARI).

Heavenly Blue (rich blue) — plumosum (for a cold house)

HYACINTHUS.

The species mentioned is truly a hardy gem.

amethystinus (a real pale blue)

HYACINTHS (DUTCH) FOR THE OPEN GROUND.

First sized bulbs are too heavy. I prefer *second* or even *third* sized bulbs.

General de Wet (pale pink) — General Pelissier (red)
Grand Maître (blue) — Innocence (white)
Lady Derby (rose pink) — Schotel (pale blue)

FOR POTS.

It is necessary to get *prepared* hyacinths to have flowers at Christmas. I prefer Cynthellas (miniature) to larger-sized bulbs. The same varieties do duty for both Cynthellas and also for larger bulbs.

Innocence (white) — Jacques (pale pink)
Queen of Pink. — *Menelik (darkest blue)
*Orange Boven (ruddy apricot) — King of the Blues.

(* Second sized bulbs recommended. Two or three first sized bulbs for those who like the old-fashioned big spikes.)

Digitized by Google

Chestnut-flower (semi-double pink)
Distinction (not large, claret)
Corregio (white)
Johan (lavender)
Perle Brillante (pale blue)

TULIPS.

As in the case of daffodils, varieties are as the sand of the sea shore in number. To reduce these to tabloid form in a thoroughly satisfactory manner is beyond the power of man. The more you know, the more hopeless does it seem: yet this means that those who know but little, need all the more help. I hope my selections may be of some use. For detailed descriptions catalogues must be consulted. Thanks to the Royal Horticultural Society, both tulips and daffodils have been reduced to something like order.

THE BEAUTIFUL WATER-LILY TULIP (T. KAUFMANNIANA).

(1) DARWINS.

A FINE TWELVE FOR OUT OF DOORS.

Clara Butt (pink)
Eclipse (maroon)
Edmée (rose edged pink)
International (ruby-red)
Petrus Hondius (rose)
Suzon (pale pink)
Duchess of Hohenburg (lavender-mauve)
Faust (very dark)
Millet (rich crimson)
Pride of Haarlem (cerise)
Teddy (rich red)

(2) COTTAGE VARIETIES FOR OUT OF DOORS.

I hope yellow and brown shades are not overdone, but I think many people besides myself have a weakness this way.

Avis Kennicott or Mrs. Moon (deep yellow)
Boadicea (mahogany and orange)
Gesneriana major (bright crimson)
Marksman (scarlet)
Moonlight (pale primrose)
The Fawn (fawn and cream)
Bronze Queen (biscuit brown)
Ellen Willmott (primrose)
Goudvink (tortoiseshell)
Louis XIV (purple and bronze)
Prince Albert (copper-brown)

(3) FOR POTS (EARLY VARIETIES).

To get away from the beaten track, I suggest:

Brunhilde (white, yellow flamed)
De Wet (magnificent orange)
Jenny (rose)
Cardinal Rampollo (orange and yellow)
Max Havelaar (orange-rose)
Prince of Austria (sweet, orange-red)
Rising Sun (rich yellow)
Spaendonk (flesh and cream flamed)

(4) DARWINS FOR POTS IN MARCH.

Baronne de la Tonnaye (rose edged blush)
Le Nôtre (rosy pink)
Pride of Haarlem (cerise)
The Bishop (purple)
William Pitt (dark scarlet)
Erguste (lavender-mauve)
Farncombe Sanders (rosy scarlet)
Sweet Lavender (rosy-mauve
The International (ruby)

(5) SPECIES.

Dasystemon (white, large yellow centre)
linifolia (sealing-wax red)
Sprengeri (scarlet)
Kaufmanniana (palest primrose)
persica (yellow)

IRISES (BULBOUS).

There is a good deal of uncertainty about the names of the varieties in the different sections. The Dutch flower the first, then the Spanish and lastly the English. Dutch and Spanish need light ground; English, stiff ground.

(1) DUTCH.

Apol (lavender and white)
Hart Nibbrig (blue and mauve)
Rembrandt (blue and yellow)
Van Everdingen (yellow and cream)
David Bles (violet-blue)
Poggenbeeck (dark blue)
Van der Helst (pale yellow)
Voerman (white)

(2) SPANISH.

Cajanus (yellow)
Prince Henry (purple and bronze)
Rossini (lemon and white)
Souvenir (soft mauve)
W. T. Ware (primrose)
Flora (white and pale mauve)
Queen Wilhelmina (white)
Royal Blue (deep blue)
Thunderbolt (bronze)

(3) ENGLISH (names uncertain).

Amazone (white splashed claret)
La Marquise (purple)
Perle des Jardins (lavender)
Rosalie (rosy purple)
Duke of Clarence (blue shades)
Princess Juliana (best deep blue)

(4) SPECIES.

reticulata (blue-purple and orange)]

NARCISSI (DAFFODILS).

Daffodils for show are outside the purpose of these selections. Most red edges and red cups burn planted out of doors. Most varieties except the polyanthus-narcissus varieties and the small species do well in grass. In grass plant clumps or drifts with one variety only, never plant mixtures. See dealers' lists for detailed descriptions.

TWELVE VARIETIES FOR OUT OF DOORS.

Barrii conspicuus (red edge to cup)
Emperor (yellow)
Empress (white and yellow)
Mme. de Graaff (creamy white)
Norah Pearson (pale yellow and white)
Virgil (a poet)
*Whitewell (orange and white)
Blackwell (red cup)
Campanelle jonquils (rugulosus variety)
Lady Margaret Boscawen (white and yellow)
Olympia (yellow)
Sir Watkin (yellow)
*Lucifer (red cup)

(* If the soil is light.)

TWELVE VARIETIES FOR POTS.

Almira (improved ornatus)
Aspasia (bunch flowered)
Firebrand (red cup)
King Alfred (rich yellow)
Lucifer (red cup)
Weardale Perfection (yellow and white)
Admiration (bunch flowered)
Cervantes (pale yellow)
Golden Spur (deep yellow)
Lady Moore (red edge)
Orange Blossom (bunch-flowered)
W. P. Milner (nearly white under glass)

(*Note.*—Under glass, red cups and red edges do not burn, as a rule.)

ORNITHOGALUM (STAR OF BETHLEHEM).

nutans (silvery grey)
umbellatum (white)

SCILLA (SQUILL).

sibirica (blue)
Sibirica alba (white).

Digitized by Google

SCILLA (WOOD HYACINTHS).

The nomenclature is confused. Some prefer the nutans—the shepherd's crook type of spike—others the hispanica, candelabra-shaped spike. Three of each type are given.

hispanica alba maxima (white)	nutans alba major (white)
hispanica Blue Queen (blue)	nutans major (blue)
hispanica Rose Queen (pink)	nutans rosea (pink)

IRRESISTIBLES.

Just in time for this article I had a private letter from Mrs. Frances King in which she mentioned a paper she had written for a recent Bulletin of the Garden Club of America, called "The 1924 Irresistibles." The "pretty title was not my own," she said, "but the invention of a friend." I hope that friend will not mind my borrowing it too. It expresses so well the idea which governs my selection of the following medley:

(A) FOR POTS.

Daffodil cyclamineus (yellow)
Daffodil Lady Moore (red edge to cup)
Early Tulip Cramoisi Royal (rosy carmine)
Late Tulip Zany (straw and carmine stripes)
Ixia viridiflora (pale green)

(B) FOR OUTSIDE.

Cottage Tulip Arethusa (THE yellow)
Parrot Tulip Fantasy (pink and green)
Double Tulip Rose la Reine (red shade of its own)
Dutch Crocus Maximilian (pale silvery mauve)
English Iris Princess Juliana (large rich blue)

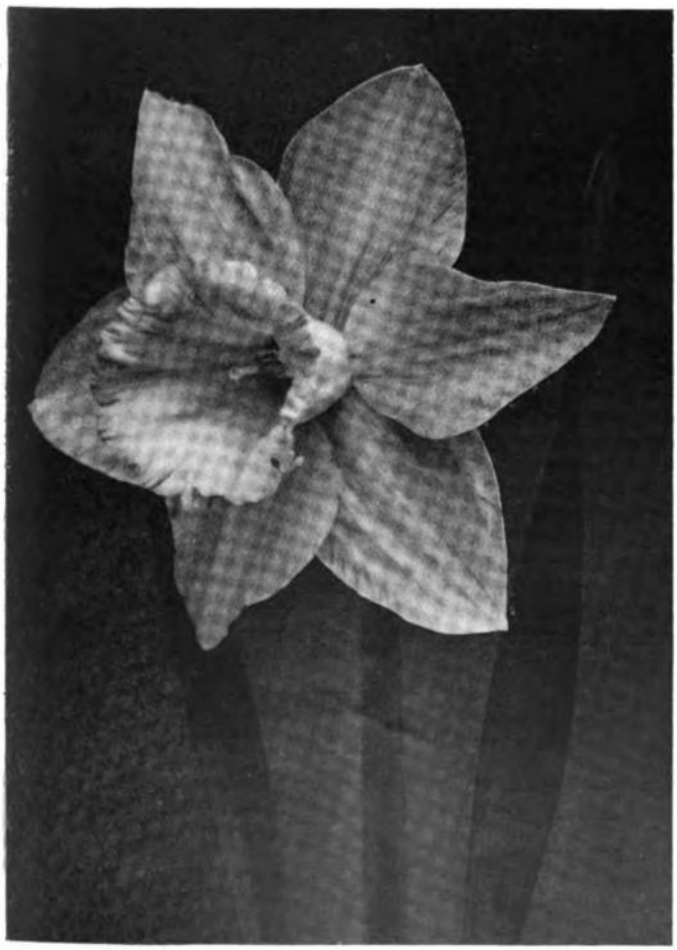
Mrs. King stated where her "Irresistibles" were to be bought. I again take a leaf out of her book and, to facilitate a purchase, state that the tulips Cramoisi Royal, Arethusa and Rose la Reine may be had from Tubergen of Haarlem, and Zany from Dobbies of Edinburgh. English Iris Princess Juliana from Barr of London. The others are "current coin" in the bulb world; most firms, such as Robert Sydenham, Limited, can supply them. Get all, and then, when you go into your houses and gardens next year, you will often be what Mrs. Fezziwig was at her husband's Christmas party, "one vast substantial smile." JOSEPH JACOB.

MODERN TREND OF NARCISSUS EVOLUTION

BY GUY L. WILSON.

AT THE MOMENT THIS IS IN THE DIRECTION OF LARGER FLOWERS OF INCREASED SUBSTANCE TOGETHER WITH STRIKING COLOUR.

IN spite of the fact that narcissi take from five to seven years to flower from seed, their more recent evolution has been rapid and striking. How striking could better be realised were it possible to stage some of the winning groups in the principal classes at say this year's Midland Daffodil Show side by side with the groups that won in the same classes twenty years ago. Eminent hybridists have been working steadily on the flower for many years, and others are taking up the entrancing pursuit of seedling raising, so that large numbers of new seedlings appear at our shows each spring, and older varieties are gradually superseded. Speaking generally, the trend of development is in the direction of much larger flowers, of increased substance and more massive build, with greater breadth and flatness of perianth segments, together with some striking developments in colour. Taller habits of growth and increased vigour of constitution have also been attained, and the various sections are becoming more and more merged into each other as a result of continued intercrossing of all classes.



BEERSHEBA, THE HIGH-WATER MARK IN WHITE TRUMPETS.

ONE OF THE GIANT WHITE LEEDSIIS.

Digitized by Google

A brief review of the main sections may be of interest. In yellow trumpets it has been found easy to obtain flowers of great size, but very difficult to achieve refined quality and well balanced form in conjunction therewith. There are, of course, occasional exceptions, and there has been a marked advance in the depth and richness of colour of our yellow trumpets. At one time all our large broad-petalled yellow Ajaxes were of the Emperor type of colouring, but now one sees many large handsome flowers of deep self yellow comparable to that of Golden Spur and even Maximus. In white trumpets it is somewhat easier to obtain refined flowers, and there have been remarkable advances not only in size, quality and purity, but in vigour of constitution. In the 1887 edition of the late William Baylor Hartland's "Original Little Book of Daffodils," there is a beautiful illustration of nine varieties of white trumpet daffodils then known. They were of the moschatus and cernuus type, and were all small flowers having an exquisite grace and charm peculiar to themselves, but they were almost impossible to keep in health. With the advent of Madame de Graaff a new race of white trumpets was evolved which had larger and more upright flowers, and combined great beauty and refinement with vigour of constitution; these however nearly all had the fault of being too short stemmed, but this defect is being overcome in the newest varieties now appearing, some of which also show a remarkable advance in size and purity. In the Incomparabilis and Barrii sections there is at present a great vogue for varieties with highly coloured crowns; this phase of development is partly due to the large number of very remarkable flowers raised by the late Mrs. R. O. Backhouse which have made their appearance at recent shows; formerly bright colour was confined to the smaller flowers and generally to the rim of the corona, but Mrs. Backhouse has produced many large flowers with big wholly red crowns. Among the newest additions to this class some large-crowned flowers of splendid substance and quality are now appearing in self shades of deep rich yellow. The progress in the Leedsii section has been particularly striking. I read many years ago a paper by Mr. Engleheart entitled, if I remember rightly, "Prospect and Retrospect in Daffodils"; one of the tasks he then set himself was the achievement of a white Sir Watkin, but a Sir Watkin would be an insignificant dwarf compared with some of the astonishing and glorious great water-lily-like white flowers he has given us recently. The Brodie of Brodie and other raisers have also produced large pure white Leedsii forms of the utmost beauty and refinement; and of late occasional flowers have been exhibited showing enchanting tones of buff and delicate shell pink in the crown. A new family of very late-flowering flat-crowned Leedsiis that bloom along with the Poets have come into being; they are among the most refined of all narcissi, being of very beautiful quality; some are purest snow white throughout both perianth and eye, with only a touch of vivid green in the centre of the eye, while others are rimmed with delicate tints of orange or pinkish orange. In the hands of Mr. Engleheart the Poets have been developed to a point of perfection beyond which it is difficult to imagine much further improvement.

It is rash to forecast what developments may take place in the future, but some may be suggested as reasonably probable. By mating our best yellow trumpets with the finest deep yellow giant Incomps., or a flower such as the magnificent "Fortune," we shall probably get a vigorous race of rich yellow Ajax of fine form the trumpets of which do not overbalance the perianth in length. Unsuspected possibilities in the colour of yellow trumpets were indicated in a most beautiful flower called "Brimstone," shown in 1923; it is very large, of great substance and attractive form, while its colour is a wonderful clear luminous sulphur, quite distinct from anything seen hitherto. Apricot and buff yellows may also be possible, but from the æsthetic standpoint not so desirable as the clear golden and lemon tones peculiar to the daffodil. The high-water mark up to date in white trumpets has been attained in Beersheba, a flower of Mr. Engleheart's raising; it is of exceptional size and has all the qualities of a fine show flower, while its supreme beauty of line redeems it from any stiffness; it is also of a whiter quality than any white trumpet hitherto, it is a tall plant and in vigour of habit and rate of increase shows a marked advance; it will take a lot of beating, but it may be the forerunner of finer whites than we have had up to the present. Some of the Brodie of Brodie's newest seedlings in this class are wonderful flowers, combining immense size and substance with perfect refinement; and when such flowers as these are intercrossed with Mr. Engleheart's largest and tallest giant white Leedsiis—for example. "Tenedos"—we may expect pure whites of still more wonderful stature and size, so it is easy to imagine that in the future we shall have white daffodils that are noble indeed, rivalling the stateliest lilies. We may soon have some finer large short-crowned white Leedsiis than any yet seen, and it is quite likely that we shall see more pronounced examples of true pink colouring in the crowns of Leedsii forms, and even in white perianthed trumpets. Barrii seedlings have been exhibited of which the perianths showed a strong suffusion of buff pink; such colouring is probably capable of further development, but while very attractive as seen in faint tones in the crowns of otherwise white flowers, these pink-perianthed Barriis seem rather out of keeping with the rest of the family. Even more startling things among red-cupped flowers will doubtless be evolved; hitherto, however, these have all been found to fade badly in sunshine, and, unless sunproof varieties can be produced, their popularity in future is likely to be limited to exhibitors; except in the case of a few varieties such as that splendid Barrii "Firetail," which are admirable for cutting and market work. As I have already said, further development in Mr. Engleheart's best Poets is difficult to conceive, but he told me in a letter some weeks ago that he has indications of a remarkable break of all red eyes in some of his newest seedlings of the finest late blooming type.

The flowering season is still capable of extension at both ends. In time we shall almost certainly have not only yellow trumpets but whites, and Incomps. and Leedsii forms of fine size and quality contemporary with our present first earlies. The superb and gloriously-coloured giant Incomp. "Fortune" is an epoch-making advance in this direction. opening as it does practically along with Golden Spur, its future as a market flower is practically unlimited. It is equally probable that good examples of all sections will yet appear the flowering season of which will be contemporary with our late Poets; among my own seedlings there are one or two fine large golden trumpets which remain in good condition till Poeticus recurvus is fully out. Some of the big whites are very late, and it should not be difficult to breed still later ones which would be of great value in the garden as well as for cutting in hot May weather, as they develop particularly finely in such conditions, and suffer no disfigurement from the sun, the strong light of which enhances their purity.

Most leading hybridists make refinement their first consideration, so that we may expect still further improvement in the quality of flowers; this is all to the good. Of course the question as to whether the flower is being developed on the best lines is a debatable one; we raisers are perhaps too much inclined to work with a single eye to obtaining fine show flowers, judged by our present florists' standard. The point before my mind is more fully expressed in the following paragraph, which I quote from a letter written by Mr. Engleheart in 1918. "It is interesting and no doubt necessary to drive at the round broad petalled erect type of large flowers, but for myself I weary a little of it, and am a good deal refreshed by a bunch of some of my more starry and loose flowers with distinct qualities of colour and grace." It would be a great pity if flowers like such charming and graceful old varieties as Frank Miles and Mrs. Langtry were lost sight of; there is ample room for both types, and if our show committees would provide a class for decorative flowers to be judged as such they would render good service.

In conclusion, may I say that I do not presume to have dealt fully with this subject, the space at my disposal being too limited for anything further than the most superficial survey.

BULBS FOR LITTLE POTS

BULBS IN POTS HAVE A CHARM AND DECORATIVE VALUE ALL THEIR OWN. A FEW OF THE UNDERNOTED SPECIES SHOULD BE TRIED.

WE want plenty of handsome pots of tall-growing bulbs—daffodils, hyacinths, tulips, etc.—wherewith to brighten the early spring days in the greenhouse. That goes without saying, and is an aspect of the matter which is certain to receive attention. What is not so obvious is the charm of the smaller bulbs grown in little pots and used to decorate the front of the staging — or any other place to which they may be suited. One of the most delightful and enduring table decorations it has ever been my good fortune to meet consisted of nothing more elaborate than the common blue and white grape hyacinths, grown in small pots which, when they were brought into the greenhouse to force, had pieces of selaginella dibbled into the surface, so that the dainty flowers sprang from its emerald carpet. One may be forgiven this suggestive little digression from our subject, in view of its applicability also to so many other bulbs.

Cultural details do not differ from those usually employed, but it should be noted that one cannot anticipate the season too much and, for whatever purpose they may be required, the earliest flowering bulbs should be forced first, and later-flowering kinds brought in at a correspondingly later date. Only the mildest heat should be used, especially in the case of the hardier naturally early-flowering kinds, such as crocus. Any attempt to hustle these simply results in the buds drying up within those curious papery cases within which they are enfolded.

Speaking of the crocus brings to mind those many beautiful species that flower long before their larger showier Dutch-brethren that have so largely ousted them from their old-time position in our gardens. One of the best of these is Cloth of Gold, otherwise C. susianus. So early is this that we may justly term it a winter bloomer. Certainly, with plenty of roots and the gentlest persuasion in the form of heat, the lovely golden yellow flowers, striped with brown on their outer petals, may be obtained very early in the year. Much later, but equally charming, is Cloth of Silver—C. versicolor—with its white flowers so prettily feathered with deep purple. This should not be brought inside until the former has passed out of flower, otherwise it will go "blind." The corms of these are small, and five or six may readily be packed into a 3in. pot.

The Babiana, unfortunately, has no English name except "baboon root," which is nearly as bad; but if you are a lover of brilliant colour, this will certainly give it to you. It is a splendid plant for little pots, for it must be confessed that success in the open air is more or less of a gamble. Grow them in a cold frame through the winter and do not place them in heat until March is in. The foliage is deep green, compact and rather hairy, and the flowers blue, rose, pink, crimson, etc.—in some cases sweetly scented.

One of the most delightful little pot plants of all is a "star tulip," listed as Calochortus Benthami. This is the dwarfest of its family, not exceeding a height of 4ins. to 6ins., while the charming little open cup-like flowers are vivid yellow with a dark blotch at the base covered with yellow hairs. This is good in a cold house where no artificial heat at all is used, and, in this way, it flowers in late April or early May. Were it not for their high cost, many of the true tulip species would form ideal plants for our purpose, but this inhibition does not apply to Tulipa persica, a marvellously brilliant little gem that glows with the blaze of living gold. Its height is under 4ins. and it bears gentle forcing well. The flower stems are branched and bear several flowers on each, while these are deliciously fragrant. While closed, one has but little idea of their colour possibilities, for the outside is a golden bronze; but when fully open into star-like divisions, the interior makes the buttercup appear a pallid and anæmic-looking flower indeed.

Responsive to similar culture to the Babianas, the Sparaxis—African Harlequin Flower—is even more vivid, and it would be difficult to imagine a more striking sight than the combinations of scarlet, black, orange, etc., with which both petal and tube are decorated. The height is about 6ins., and bulbs are usually sold in mixture at cheap rates. No heat should be used if you grow Cyclamen Coum, for the plant will not stand this, although it is perfectly happy in a cold frame. For occasional use in the house it is a perfect miniature of the larger Persian forms, with round deep green foliage and tiny rose-hued flowers produced very early in spring. Grape hyacinths are many and varied, but for our purpose nothing excels those old favourites, Muscari botryoides cœrulea and alba. These begin flowering in the open ground at the end of March, so that it will be seen that a very little is required in the way of artificial heat to anticipate this by some weeks. If one begins carefully, these are among the easiest of bulbs to force, but heat should be moderate and the soil not allowed to become dry.

If you love curios, try some pots of the Plume hyacinth, Muscari plumosum; but do not crowd the bulbs of this, or failure will follow. One bulb in a 3in. pot is sufficient, and when this flowers you will obtain a fine violet feathery plume that, on the closest examination, is as little like a living flower as anything that you ever saw. Especially valuable for small pots is Milla uniflora, so happily named Spring Star Flower. This is pure white, star-shaped and shaded with blue lines, and is deliciously fragrant. The variety uniflora violaceæ differs only in its colour — a clear porcelain blue — while both produce their flowers in succession, so that they remain decorative over a long period. Its natural season may be anticipated by forcing, but too much heat is to be avoided.

Use them how you will, group them how you will, these little pot bulbs are going to be an enormous asset in the spring flower scheme, whether used in the house or the greenhouse.

H. W. CANNING-WRIGHT.

THE UTILISATION OF BULB PLANTING

THE VALUE OF BULBS IN MEADOWS, IN WOODLAND AND BY THE LAKESIDE IS INESTIMABLE, GIVING AS THEY DO SOME OF THE FINEST SPRING SCENES THAT ONE CAN WISH TO SEE FROM SNOWDROP-TIME RIGHT ON TO TULIP-TIME.

ONE of the commonest mistakes made when naturalising bulbs is that of over-planting, *i.e.*, filling the whole ground so thickly that the relief, repose and charming simplicity which often come from the use of even a few thoughtfully placed flowers are totally lost. Once free of the garden proper our aim should be the production of picturesque and artistic effects, and therefore—if our efforts are to be successful—beds of any shape whatever must disappear from our mind. The beautiful effects arising from such planting are scarcely possible inside the garden proper for many reasons, hence the value of permanent planting in meadow, woodlands and by streams and lakes. In such places we can plant with a lavish hand many species of bulbous flowers and depend upon them for charming pictures over a period of years. Here it has been the practice to scatter the bulbs broadcast, each bulb being planted where it falls, and by this means a prettier outline is obtained than when setting out the bulbs one by one.

Another effective method from which happy results arise is that of placing the bulbs in lines along the margins of paths and streams as seen in the accompanying illustrations, narcissi and snakesheads revelling right down to the water's-edge. Narcissus Emperor reaches 3ft. 6ins. in height under these moist conditions and produces sheaves of handsome blooms, which improve in effect as the grass becomes greener each day, and in one instance where this streaming mass clothes the ground beneath a group of crimson ribes the effect is charming. Once established, narcissi are difficult to destroy for, when cleaning out the upper lake three years ago, those shown between the oak tree and the cottage were covered with 12ins. of mud and are now stronger than ever. This also assists in proving that the depth at which such bulbs should be planted is not a serious consideration.

Narcissi will grow in almost any soil, but they flourish best in a cool loam and prefer partial shade, such as that afforded by thin woodlands and orchards, where the apples are generally in bloom at the same time. Daffodils are undoubtedly the most popular flowers for planting of this nature, but there are many other species of bulbs which are of equal value for naturalising and these include:

SNOWDROPS, our earliest spring flowers and old favourites of English gardens, are undoubtedly seen at their best when carpeting the ground beneath thin woodland scrub. They have also a considerable attraction when grouped in meadows and on the banks of streams. One can have the choice of whites, yellows, greens, including the magnificent large-flowered kinds, with drops 2ins. long, from Asia Minor and the Caucasus, but the latter are somewhat difficult to obtain and therefore for our present requirements we should confine ourselves to Galanthus nivalis in its various double and single forms; G. Elwesii, of which many handsome forms exist, notably the var. globosus; and G. Imperati, all highly desirable for our purpose. It is a mistake to plant snowdrops under lawn trees as when it is raining the drip spoils the flowers.

SNOWFLAKES (Leucojum) are larger in all their parts, although closely allied to the snowdrops. They like a warm rich soil, in which they thrive and increase with the same rapidity

DAFFODILS BRAVING THE MARCH WIND[S] ... RAVETYE MANOR.

DRIFT PLANTING BY THE WATERSIDE.

as the daffodil. L. æsvitum grows about 18ins. high with daffodil-like leaves and from four to six white bell-like flowers are borne on spikes 18ins. in height.

There are other varieties of this species, but greatly in advance of any known to me is Gravetye Giant, a strikingly handsome plant which reaches 3ft. in height and carries stout spikes each with seven or eight fine blooms, which are larger and whiter than those of the type.

None should overlook the value of the Vernal snowflake (L. vernum) and its lovely varieties carpaticum and Vagneri, none of which exceeds 1ft. in height. From the tuft of polished strap-shaped leaves there arise the stout spikes carrying two pretty green or yellow tipped flowers. Little colonies of these plants in the grass are always a charming feature.

CROCUSES.—Few bulbous flowers naturalise more freely than these and none is capable of producing more brilliant effects so early in the year, and when planted in the vicinity of large trees the changing shadows enhance their charm at all hours of the day. These are in bloom long before the majority of spring bulbous flowers and therefore may be scattered over the surface and planted where they fall even though later flowering bulbs such as the Italian or Spanish squills may occupy the same ground to carry on the picture long after the crocuses are past.

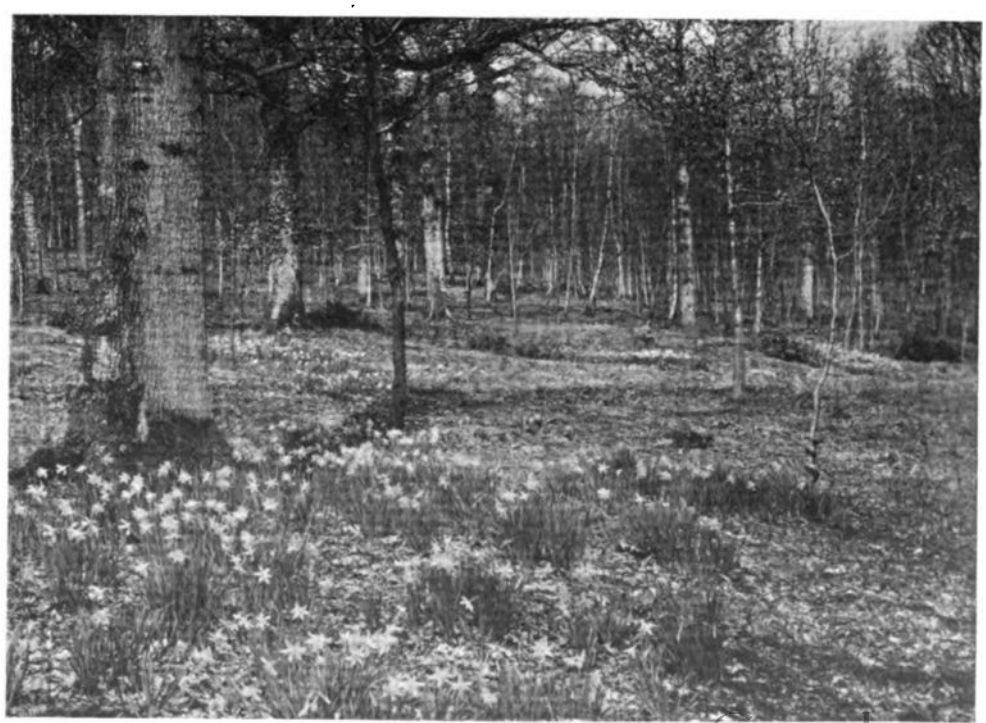
The varieties of crocus are so numerous that it becomes a question of choice what colours to plant. A few species, however, which produce lasting effects may be mentioned, including CC. vernus, Imperati (the earliest of this genus to bloom), susianus, biflorus (known as the Scotch crocus), etruscus, versicolor, Sieberi, chrysanthus, stellaris, and the lovely September-flowering C. speciosus. Crocuses do well in an upland soil where they become baked in summer and they never appear better in effect than when stretches of unplanted green sward divide the drifts of flowers.

ANEMONES.—Next to the glorious array of crocuses come the windflowers in their delightful forms and colours, the whole genus revelling both in sunshine and partial shade, developing picturesque features surpassed by no other plants. The first to bloom is the Greek Anemone blanda, a lovely large flower which may be obtained in white, blue and crimson shades of colour, all of which are remarkably effective both in grass and woodland.

Close upon its heels comes the scarlet windflower (Anemone fulgens) in its various forms and a more pretty effect when intermingling with grape hyacinths and golden daffodils could scarcely be desired. This brilliant flower dies out in rich ground with me, but flourishes from year to year in orchard meadow.

The snowdrop anemone (A. sylvestris) flowers late in the season and is partial to a little shade, it is a graceful flower and should not be omitted. A. nemorosa adorns our fields and hedgerows and therefore we have no reason to add to it, but of its fascinating varieties we would plant generously at the sides of orchard paths, by streams, meadow ridges, and indeed everywhere, by reason of their enhanced beauty in relation to other plants. Who would omit from their collection a colony of that precious windflower known as A. n. var. Robinsoniana, with its myriads of sky-blue flowers which close at the approach of storms and on sunny days follow the sun from east to west. I consider this the most beautiful windflower in cultivation and in heavy soils it increases like couch grass. Other lovely kinds exist, such as Allen's variety and cœrula; there is also the Appenine anemone, as free as a weed either in garden or meadow, where it gives one a picture of unusual charm and loveliness.

The cyclamen-leaved anemone (A. palmata) is a little more particular and requires a well drained soil in partial shade, whereas the yellow wood anemone (A. ranunculoides) will flourish almost anywhere. The star windflower (A. stellata) must have a high and dry sun-baked position, but is a less important plant.



BROADCAST PLANTING IN THE WOODLAND.

BETWEEN LAKE AND PATH AT GRAVETYE.

TULIPS, so distinct and brilliant in the colour of their flowers, are responsible for striking effects, but less permanent than the foregoing and should be renewed from time to time. TT. macrospila and fulgens bloom with the moon daisies and are the most satisfactory of a number of varieties tried in the grass.

DOG'S-TOOTH VIOLETS (Erythronium) are fascinating plants for meadow and woodland and also along the fringes of carriage drives, where their pretty mottled leaves and elegant flowers are always a subject of admiration and charm.

SNAKESHEADS (Fritillaria) belong to the lily family and are among the most graceful flowers grown. F. Meleagris in all its varieties revels in the moist meadows near the waterside, where a few plants have increased to such an extent that they now cover a quarter of an acre. The delicately coloured bell-like flowers are poised on elegant stems about 18ins. high and there is a very choice white variety which planted in thin trails along the sides of grass paths is an object of singular beauty.

SCILLAS are decidedly effective in the grass and comprise some of our most exquisite blue flowers. S. taurica, from the Taurian mountains, is the first to bloom and is followed by SS. azurea, amœna, sibirica, in a variety of colours, including a choice white variety. The great Spanish squill (S. hispanica) is the largest of the group and an extremely handsome plant which loves a moist position such as obtains near the waterside and in low woodland places. S. italica, a charming pale blue flower revels on the higher grass slopes and with the exception of S. amethystinus, which blooms at the end of May and early June, is the last of the squills.

THE SNOW GLORIES (Chionodoxa) comprise CC. Alleni, cretica, the iridescent CC. gigantea, sardensis, Luciliæ, nana and Tmoli, all desirable plants for naturalising and much varied in colour, including blues, both deep and pale, whites and mauves.

THE SPRING STAR FLOWER (Triteleia uniflora), from South America, produces sheets of white and pale blue flowers when planted on warm slopes.

THE QUAMASH (Camassia) is a North American plant of the lily order which thrives luxuriantly at the waterside, where it attains from 4ft. to 5ft. in height. The principal kinds are CC. Cusickii, esculenta, Fraseri and Leichtlinii.

LILIUMS.—Two lilies at least thrive among the natural vegetation by the waterside, namely LL. umbellatum and pardalinum, the latter known as the Panther lily.

THE MEADOW SAFFRONS (Colchicum) are also desirable for autumn effect and naturalise freely. C. autumnale and its varieties are the first to bloom and are succeeded by the more handsome CC. speciosum, speciosum album, byzantinum, cilicicum and Bornmulleri, a fine species from Eastern Europe.

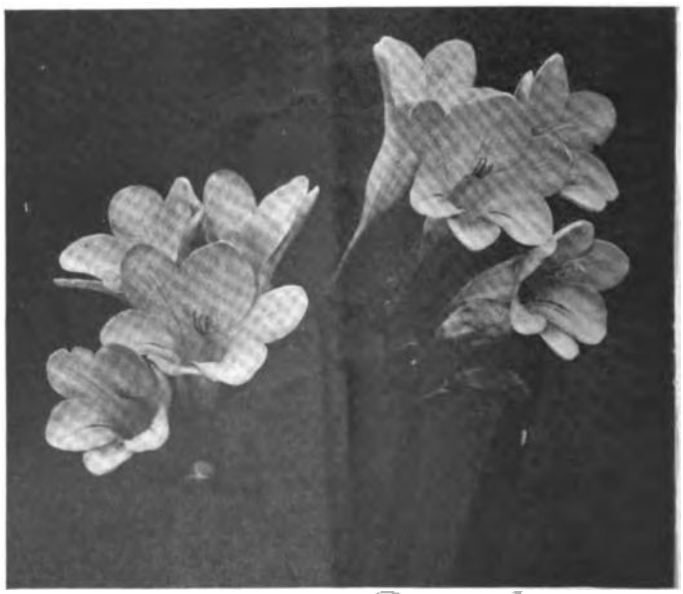
These notes would not be complete without reference to the SOUR BREADS (hardy cyclamen), most of which should now be planted. The shade and shelter such as a branched yew or other evergreen tree affords, and over the roots of which a fair quantity of decayed leaves has been strewn, are what these free-flowering plants enjoy and the pleasure a well flowered colony produces under such circumstances is a fitting reward for one's labour.

ERNEST MARKHAM.

THE CULTIVATION OF FREESIAS

OF FRAGRANT PLANTS NONE IS MORE WELCOME THAN THE FREESIA.

FREESIAS, "dear delightful Freesias the werry mention of whose name kivers me with the creeps and thrills me all over with joy." Had the celebrated John Jorrocks been an ardent freesia grower he would have expressed himself thus, and exhorted his boy, "Binjimin," to eschew tipcat and marbles and turn the maincock of his mind entirely to freesias, "and I make no doubt but what you'll rise to be a werry great man." To those who do grow freesias I say grow more, and to those who have never grown them I say try them. They are very easily grown, whether you have only a cold greenhouse, a frame or a heated greenhouse. They do not require more heat than is necessary to keep out frost. Coloured freesias originated, I believe, from a rosy pink, F. Armstrongi, found by Mr. Armstrong at Humansdorp in 1898. The first yellow was, probably, F. aurea, introduced by Messrs. Wallace. I think without doubt Messrs. Van Tubergen have done more work in raising coloured hybrids than anyone else, and most of the varieties in commerce which can be bought in quantity are of their raising. There are other raisers, like myself, who have many good varieties, but stocks are not yet large enough to be offered to the public. Mr. Chapman of Rye, who turns his hand so successfully to raising all sorts of new plants, brought out some fine hybrids of particularly good form, but I think daffodils now claim most of his time.



THE ESPECIALLY FRAGRANT LILAC FREESIA MOUETTE.

Digitized by Google

FREESIA APOTHEOSE, ADMIRABLY SUITED AS A POT PLANT.

Messrs. Charles Smith of Guernsey have also dropped them to a great extent. Which is a pity, for both these raisers could do good work still. I had a very fine golden yellow seedling from Messrs. Smith this spring; but I think rare shrubs and rhododendrons claim their attention chiefly now. Mr. Joseph Jacob of Whitewell is going strong as a freesia champion, and I feel sure the word "freesia" thrills him all over with joy. He has raised a good many fine things and is very strong in good rich yellows; and then there is myself. Of all the seedlings I have raised—and, for that matter, anything that anyone else has raised, so far as I have seen or heard—nothing surpasses the variety Wistaria. It may sound like boasting and blowing one's own trumpet, but I stand by it, and the consequences. Everyone who has seen this variety growing here will bear this out. I hope it will be put into commerce next season.

Propagation of freesias is either by offsets or seeds. Seeds of the hybrids, of course, do not come true, but one never knows what one will get. Seed is easily raised, and I prefer sowing early in August and give the young seedlings all the benefit of the sun until the days get short. Some 50 per cent. or more, if grown well, will flower the following spring, but are never large enough to be judged, and should be grown on a second season. At one time there was a good deal of trouble with certain growers through the corms not growing after being potted. I always maintained it was due to insufficient ripening, and my theory has proved correct. I never get any trouble of this sort, as I always ripen the corms very thoroughly. The same result may be caused by the corms getting insufficient water after potting, but they form a new corm on top of the old one.

I presume they get drought conditions in their native land, and nature has arranged for reproduction in this way when roots would find insufficient moisture to carry on and make normal growth. Potting should, for preference, be done in August and never after September if good results are looked for.

I like a very porous compost, plenty of sharp sand, with some fine bone-meal. I do not use any manure. I think most of the goodness gets washed out every time the pot is watered, long before the roots get their full share.

In potting, select a deep pot rather than a wide one. Freesias make a long fleshy root, called a contractile root, which enables it to contract when growth is finished and draw the corm down into the soil. I find this big fleshy root likes to go down as straight as possible, and therefore a pot 6ins. deep is better than one 4ins. deep. Deep Long Toms are what I like. I grow seed in boxes as far as possible. I prefer this method, as the soil is kept in a more even condition, and I also prefer growing corms in beds for the same reason. The results when harvesting are very noticeable.

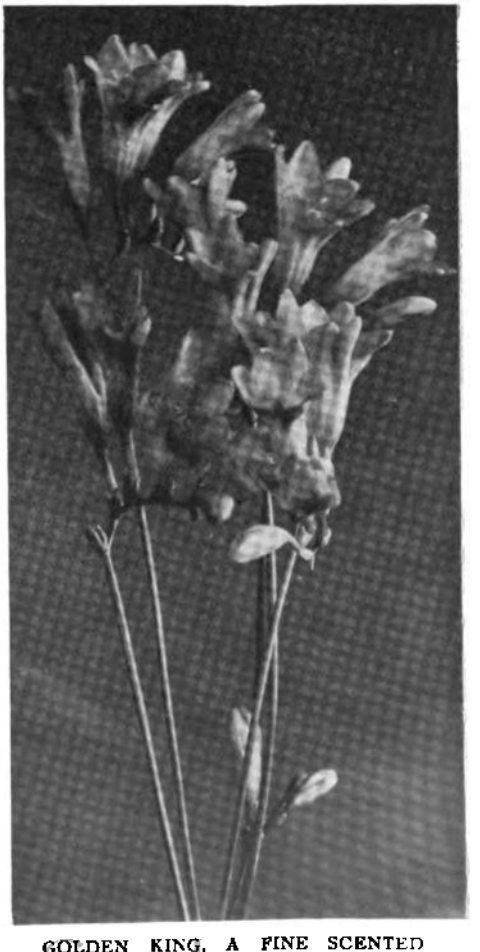
I prefer to feed them when the flower spikes are showing. If some corms are planted late, say at the end of September, in cold frames, the flowering period can be greatly extended. I had flowers until the end of June, but there are too many other flowers out at this time to make it worth while having freesias so late. February, March and April is a long enough period. Plants should be staked before they get too tall. I have no hesitation in saying Allwood's carnation supports are quite the best things to use. They are easily adjusted, are neat and tidy and last for years. I have some ten years old as good as new, and they are used every year.

I have often been asked if the coloured sorts are as sweet-scented as the old F. refracta alba. Strictly speaking, perhaps not; but no one would need to ask the question if they were here in April on a warm sunny morning. When the ventilators of the freesia house are opened, the scent is very noticeable a long way off. Pick some flowers and stand them in water in a cold dull room, and scent will probably be missing. Pack them in a box and post them, and there will be very little doubt as to their scent when the box is opened. I think the finest scented variety I grow is Golden King—not a large flower, but a grand stiff long stem and a delightful scent.

The ideal freesia should have large massive blooms, petals of good substance, standing at right angles to the tube; colour to be well into the throat, a tall stiff stem, broad massive foliage, free-flowering, and a well branched spike and a good scent. I give a list of the twelve best varieties. These are all in commerce and are grown in quantity. I leave out new and scarce sorts of which stocks are as yet small: Apogee, one of the best, of a very good shape and especially good for pots; Daffodil, new and very fine; Treasure, large and a real big grower; Buttercup, old but early and well worth growing for cutting or pots; Golden King, very late and especially good for cutting.

These are yellows; you can pick any four—they are all good.

Of mauves, La France comes first (La Frappante and Preciosa will be superseded shortly). Bluebeard (an old variety of Messrs. Van Tubergen, who have discarded it), though small, is very



GOLDEN KING, A FINE SCENTED VARIETY.

Digitized by Google

rich in colour and a good little plant for pots. Merry Widow is very free flowering, but wants more colour and more flowers on a spike.

Conquest is the best of the pinks, Dainty being paler but a good cut flower. Robinetta, the nearest to red (Red Indian (Jacob's), though small, is a rich colour and, if obtainable, is worth growing). La Charmante is a mixture of pink, orange and copper, and very effective. Apothéose is better than Jubilee and Mouette (Jubilee for pots and Mouette for cutting). These are some of the best, though some of them are old. The best way to decide is to try them for yourself, and perhaps other readers will give their opinion of those varieties which they have grown, for my list is necessarily limited to those I have grown myself. G. H. DALRYMPLE.

NOTES FROM CONTRIBUTORS

WILD PLANTS AT MINEHEAD.

AS you walk from Minehead towards Dunster along the marshy land that lies by the sea shore, many rare wild plants are to be found—clumps of tall wild yellow sweet peas, achillea, mauve, white and yellow, growing to a great height; the beautiful blue and purple viper's bugloss, growing to a height of 3ft., a decoction of which, according to Dioscorides, was a protection from viper's bite; and the yellow-horned poppy, are a few of the many plants to be seen flowering now.

The hedges of yellow St. John's wort are in bloom, and the Dunkery Moors are now a mass of bell heather, yellow pimpernels and whortleberries, the leaves of which have a lovely rosy tint.—M. L. N.

PERNETTYA MUCRONATA.

THERE are few more striking dwarf evergreen shrubs, either for the rock garden or the front of the mixed shrubbery, than this and not the least among its charms is the variability in the colours of the berries upon which its autumn charms depend.

There are varieties with rose, white, pink, crimson, purple and black berries, and—in addition to these—one has the charm of the abundant display of white flowers which precedes them earlier in the year. A member of the heath family from South America, all that the plants require to ensure their complete happiness is a sandy peat soil that never becomes dust dry. Associated with rhododendrons and other peat-loving shrubs, their autumn effects are splendid and add just that touch of interest which is otherwise apt to be lacking.—HAVELOCK.

THE MAKING OF POTPOURRI.

POTPOURRI is of two kinds, the moist and the dry. The moist is the sweetest and most enduring, but requires some time and patience for the making. The main ingredients are rose petals, leaves of sweet geraniums and sweet verbena, bay leaves and lavender; but anything of sweet and lasting scent, such as shavings or sawdust of pencil cedar, can be added. The roses should be gathered when just full blown and only when quite dry; if rain has fallen upon them, even the day before, it is apt to hang in the middle of the flower and makes it unfit for drying. For the wet potpourri the petals must be half dried. They are picked off their bases as soon as they are brought in from gathering, and laid in clean dust sheets in some well aired room. As we make it in some quantity, a roomy studio is given up for the time being; for two large, long tables and a good part of the floor are occupied by the day's picking of two or three bushels of flowers. It is impossible to say exactly how long they are to dry, as it varies with atmospheric conditions; but the rose leaves should become tough and leathery and shrunk to about half their bulk. They then go into their preparative jars, tall cylinders of earthenware, about three handfuls of rose leaves at a time; they are rammed down close and sprinkled with a good handful of the salt mixture. This is equal parts of bay salt and common salt; the bay salt is sold in knobs which must be crushed so that the largest pieces left are about the size of a small hazel nut. So it goes on till the supply of rose leaves is exhausted. The leaves of sweet geraniums, which are not ready till August or September, are torn up, dried for one day and treated in the same way as the rose leaves. Sweet verbena and bay leaves are of a drier nature and can go in as they are—also lavender, which can be used either in whole heads or shaken out.

When all is ready, a space is cleared on the brick floor of the studio and the preparative jars are brought forward. The spice mixture is also in readiness and consists of the following: 1lb. ground allspice, 1lb. ground cloves, 1lb. ground mixed spice, ½lb. ground mace, 1lb. whole cloves, 1lb. pounded gum benzoin, 1lb. pounded gum storax and 5 large packets of Atkinson's violet powder. This is for the rather large quantity we make, the produce of some twelve or more bushels of rose leaves and sweet geranium, etc., but it may be a guide as to proportion.

The prepared material is now tight in the jars; it has to be loosened and then broken up by hand, thrown on to the floor, the spice mixture being sprinkled between. Finally, it is turned over several times with a shovel to make the mixture even and complete. It is then shovelled into a wide-mouthed tub and again rammed. It is better for being kept six months at least in the tub to mature, before being taken out for use and distribution.

When potpourri is made in much smaller quantities all the ingredients can be put into one jar as they come ready, they should be salted and rammed as described, and finally broken up and the spices added.

For dry potpourri the rose petals and other ingredients are dried thoroughly indoors, spread on sheets of paper. No salt is used, but the same spice mixture in the required proportion. This kind is suitable for sachets; the moist should go into bowls or wide-mouthed jars, with or without covers.—G. J.

RAVAGES OF THE VAPOURER MOTH

I HAVE noticed that many of the London squares are ravaged this year—especially the thorn trees—by the vapourer moth, a pest usually dealt with in towns by knapsack spraying, a method only partially successful.

On June 26th of this year I noticed a large swarm of the moth surrounding an oak tree here and realising that no spray would reach the tops of our tall trees, I tried to locate the breeding ground and found it (as I rather expected), in a short stretch of a euonymus hedge. The caterpillars were just on the move, but were, happily for us, still enveloped in their cocoons. We collected two large barrowfuls and burnt them.

Some years ago, so we are told, there was not an oak tree on the property with any leaves on it and the pest was deemed undefeatable, but I think we are safe now.—ELIZA H. COHEN, *Rickmansworth*.

THE PERSIAN TULIP.

MANY of the tulip species are extremely interesting little flowers, but their high cost places them beyond the reach of the average garden. This, however, is not the case with persica. A mere half-crown will purchase a dozen bulbs of this, and it is an investment that will be repaid a thousandfold. Persica is not a tulip of a year, but comes up again and again. In my rock garden I have a splendid clump which has been in the same pocket for many years, yet each spring its glory is undimmed and there seem to be more flowers than ever. "What is it like?" you say. Well, there I begin to be enthusiastic, for to me it possesses all the graces—colour, form, freedom of flower and fragrance. Let us begin with colour. In the bud stage it gives no hint of its brilliance, for the outer side of the petals are golden bronze. Wait until the sun shines, however, and you see the interior revealed. "Gleaming golden yellow" are but poor words with which to describe the brilliant varnished gold. Speaking of the opened flowers leads us to form—which is that of a perfect star, opening nearly as flat as a table. Finally, fragrance. This is distinct from all else, but really powerful and, to complete the picture, remember that the whole plant does not exceed 4ins. in height. No special care is needed save a really sunny and rather elevated spot, and each bulb should be surrounded by a little coarse sand. Planted thus—4ins. deep—Tulipa persica will grow for you not only next spring, but for many springs after that.—H. C.

PLANTS KNOW WHAT IS GOOD FOR THEM.

MISTAKES are often made in situations chosen for plants. We put them where we think they ought to be happy or sometimes only where we think they will look well. Their ideas on the subject differ from ours and sometimes they give up and die.

Some anemones have been giving us lessons on what positions suit them best. Anemone blanda cœrulea, given a semi-shady place near a hedge, sent its seedlings on voyages of discovery. They started some flourishing colonies at the very foot of the evergreen hedge and the original patch has nearly died out.

St. Brigid anemones in spite of preparation of the site, have almost failed in the herbaceous border. This has a raised edge of stones inhabited mostly by rock plants. This spring we became aware of several very strong anemones among the stones, maintaining their preference for growing on a bank.

The lesson has been accepted meekly and thankfully.—G. D.

DIASCIA BARBERÆ.

THIS is listed in many seedsmen's catalogues as a half-hardy annual. Our experience would lead us to class it as a hardy perennial and we wonder how it has behaved in other gardens. We grew it for the first time last summer from spring-sown seed, and it bloomed profusely. To our great surprise it showed no signs of dying off in winter. The foliage did not wither till the very trying weather of late spring. New growth soon appeared from the original roots and with few exceptions the plants survived and flourished. They have now been in bloom some weeks.

It is a very charming irregular flower, much like the colour of Begonia Gloire de Lorraine, but with a slightly salmon tone. The habit is neat; the stem creeps, but not aggressively; the height is about 9ins.—G. PRICE DAVIES.

SIMPLE GARDENING

LIFTING AND STORING EARLY AND SECOND EARLY POTATOES.

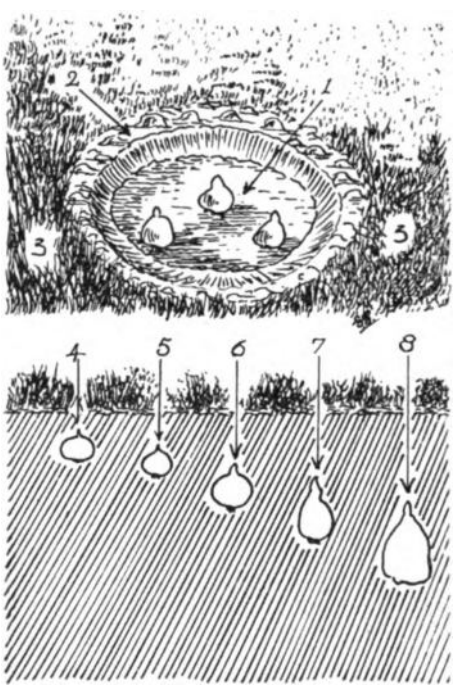
LAST year, owing to the long spell of dry weather, the second-early potatoes, in some districts, failed to reach maturity in the true sense, the tubers ripened prematurely. The tubers were undersized, but there was no disease. This year the crops are in splendid condition and there may be a risk of "growing-out" in wet ground, also of disease. Now the question is, what shall be done generally? Undoubtedly lifting and storing should be work closely attended to in favourable weather. I always try to avoid getting wet after they are lifted tubers that are to be stored. I believe in storing them with any soil adhering to the skins in a dry state in cases where the crop is grown in a heavy loam. When first lifted, the tubers should be very carefully examined for diseased ones. About ten days afterwards the tubers should again be examined prior to storing because any tubers that may be slightly diseased when lifted but not sufficiently to show clearly, will be easily observed at the second scrutiny. High, dry positions outside should be selected for the clamps and, indoors, the driest parts of dry, cool sheds. Ample protection must be provided against frosts, especially against outside walls. The seed tubers should be picked out when the crop is lifted and placed, forthwith, in single layers in boxes to become green and always exposed to the light except when frosts come.

FEEDING AND TOP DRESSING CHRYSANTHEMUMS.

Cultivators of these plants who wish to grow extra fine blooms for exhibition, are always anxious to use some stimulant that will assist in the production of such. Now, it is very important that feeding should not be general till after the buds are "taken." There are some exceptions, where plants are growing in small pots and have filled the latter with healthy roots and there is every appearance that the desired buds will be in good time. If feeding takes place too early the ends of the growing shoots become soft and pithy and the bud may not develop into a deep, full flower. The best time to begin feeding is when the buds after being taken, are swelling freely, then the stimulating foods help such buds to "plump up," as it were. I do not use nitrate of soda nor sulphate of ammonia, as both, unless used with utmost care, will kill the roots and all suckers that may be valuable later on as the basis of the season's cuttings. Concentrated manures are safe when applied with due care—in under, rather than over, full doses. But even these should not be applied if the stems of the plants soften unduly. Weak, clear soot water and liquid manures are safe, but cannot be applied often in dull, wet weather. Top-dressing is not advocated now as in days a generation and more ago, when thick layers were applied. Now, the best results follow thin layers of sifted soil and a good artificial mixed, several applications, fortnightly, being beneficial.

PLANTING BULBS IN THE WOODLAND GARDEN.

Even in many a town and its suburbs there are patches of ground which are termed wild or woodland gardens. In more open country such gardens are extensive and many of them very beautiful. Bluebells and narcissi are easily



established in some woods, but a variety adds to the general interest and enhances the beauty of the natural scenery. Suitable bulbs should be planted, of course; furthermore, they should be so treated that free growth will be the result. The soil should be well prepared and its surface kept free from grass and weeds till the plants are well established. No. 1 shows how to dispose the bulbs; No. 2, the soil to be placed on them; Nos. 3, 3, the surrounding grass. Approximate depth to plant. No. 4, snowdrops, crocuses, 2ins.; No. 5, scillas, 3ins.; No. 6, anemones, single sorts, 3½ins.; No. 7, Spanish iris, mixed; No. 8, narcissi. These are named as a guide to planting.

PROPAGATING PANSIES AND VIOLAS.

The propagation of pansies and violas from cuttings or "slips" is a very interesting work. With ordinary care taken the strains of real worth are kept up so that an annual improvement will take place and most of us know how easy it is for good strains to deteriorate. The parent plants, from which cuttings are to be taken, should be marked beforehand as it is unwise to use cuttings from old specimens straggling in growth. Those that are compact, short-jointed and healthy should be selected. Stocky plants usually possess a number of young shoots near the base and these are the right ones to take off, not the older, hollow-stemmed branches. Do not cut, but press them off with the thumb and finger, take these slips at once to a cool place and use a very sharp knife to trim off the two basal leaves and the stem below the bottom joint. Use a light compost, surfaced with coarse sand; insert the cuttings round the sides of flowerpots, where only a few are to be rooted, or in a frame turned to face the north. Failing frames, then make up a bed outside on the north side of a wall or fence. Apply water through a rose, shade from bright sunshine; firm the soil around the cuttings when they are loosened through frosts or the workings of earthworms and then there should not be many failures.

SHALLOTS AND ONIONS.

The former have not matured as early this year as they do in very warm summers, and, instead of mid-July harvesting, mid-August will be the rule. The very fine bulbs will require a little extra care in carrying out the harvesting operations. After they are lifted the bulbs should be placed where the rains will not reach them, but plenty of air, their surroundings being quite cool. The bulbs should be separated but not till they are fairly dry, this separating of the clusters taking place about a fortnight before the final storing is attended to.

Autumn-raised bulbs of onions, especially of such types as Ailsa Craig, Cranston's Excelsior, Giant Rocca, White Elephant and Leviathan, should also be harvested now. It is possible to keep the spring-raised plants growing till nearly as late as mid-October, but the autumn-raised ones would split if left in the ground after swelling ceases. The growing bulbs should be fed by boring holes 18ins. apart and 1ft. deep with an iron bar between the rows of plants. Into these holes pour the manure water twice weekly, it will reach the roots, which should be deep down at this date and not on the surface. GEORGE GARNER.

CORRESPONDENCE

A SELECTION OF RAMBLER ROSES.

SIR,—As an old subscriber to THE GARDEN I should be much obliged if you or any of your readers would give me the names of six of the best rambler roses. In the gardens of a house I have lately bought there are masses of Crimson Rambler, which I propose to root out. There are a few fine specimens of the American Pillar Rose, which, of its type, is a beautiful rose. If you could give me the names of five or six rambler roses you can really recommend, I should be indebted to you.

May I congratulate you on your present paper—by far the finest gardening paper published either here or in the U.S.A.—H. E.

[We should recommend the following as being a very good selection of ramblers: (1) American Pillar, (2) Paul's Scarlet, (3) Blush Rambler, (4) Excelsa, (5) Lady Godiva, (6) Sander's White. The first three are excellent for growing up poles, while the last three, with plenty of lateral growths, are suitable for crawling over walls. As our correspondent suggests, we should welcome the opinions of our readers on this subject.—ED.]

ROSE-COLOURED VERONICAS.

IN the useful note by "Hortulanus" (page 538) he refers to Veronica spicata rosea, the most widely cultivated of the rose-coloured herbaceous veronicas, and suggests that it "may have arisen as a cross between the type and V. hybrida or V. longifolia."

Having last month observed this elegant rose-coloured plant at Wisley and gathered and dried specimens (which are very glandular) from a Somerset garden, I feel sure it has no longifolia in it and think it may have as much hybrida in its composition as spicata, which is a species little known in England save in its native state in Suffolk and Cambridge, though frequent on the Continent. Both V. spicata and V. hybrida (which may be regarded as a sub-species) have a characteristic rosette of leaves at the base, but hybrida is a stouter, taller plant with less serrated stem-leaves, which serrations do *not* extend "throughout" as Hooker said. Both are usually pubescent, the leaves and stems of hybrida especially are frequently dull green with short down, though spicata is often greyish with longer hair and more glandular.

V. hybrida is hardly recognised on the Continent, and in Britain confined as a rare plant to a few Welsh counties and to its classic station on the limestone close to Bristol. Plants of it from St. Vincent's Rocks, which I cultivated in 1888 in my father's garden at Bridgwater, completely lost all crenation and serration of their stem-leaves by June, 1898, as two specimens in my herbarium show.

I hope shortly to write a note on Veronica spicata, V. longifolia, and allied forms and hybrids in English gardens and nurseries; for, after twenty years' observation and collection of cultivated specimens, I find much that has been named V. spicata in gardens is something very different.

It would be interesting to know exactly what is V. rosea Desf.—H. S. THOMPSON.

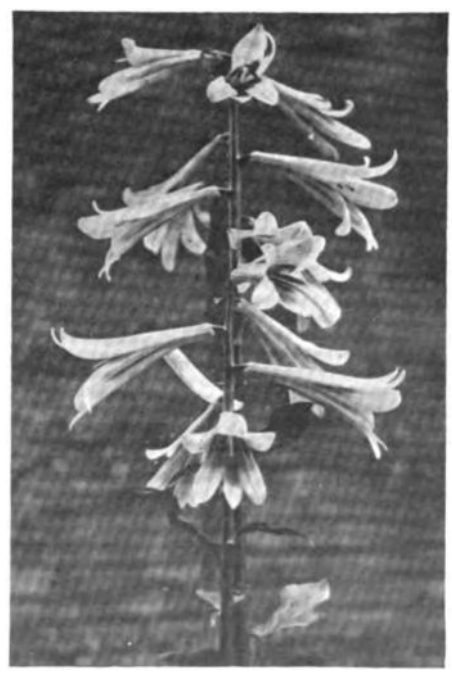
SAXIFRAGA CÆSIA.

SIR,—With reference to Dr. Wacher's queries in regard to S. cæsia on page 537, his first question, as to whether there are different forms of this saxifrage, may find its answer in the fact that Mr. Farrer recorded a major form as being prevalent at high altitudes twice the size of the type in leaf and flower in the Dolomites, and described it as being and as having the rosettes more loosely built This seems to agree with Dr. Wacher's description of the plants collected by him near Mürren.

With regard to his second question, viz., why cæsia is classed among the Kabschias, inasmuch as it seems to Dr. Wacher to be nearer to the dwarf Aizoons, valdensis and baldensis, an invitation to instruct a successful grower of cæsia and lilacina in the distinctions in type between the Euaizoon and Kabschia groups is one not lightly to be accepted. Whence I offer the following as suggestions only, and not as instruction. S. valdensis is a Kabschia, though confused (in gardens and by Mr. Farrer himself in 1913) with S. cochlearis minor. The Kabschias do not really form rosettes at all. The shoots are cylindrical or columnar in form with imbricate leaves, whereas those of the Aizoons tend to be naked with rosettes at the tip end. This main distinction, clear as it may be in the types, is not so easy as it reads in the miniatures. I have not seen S. A. baldensis—it is not when the heavens are let loose, as was the case when, in June last, I was on the highest rocks of Monte Baldo, that one chooses to peer about for miniatures—but I suggest that the shoots are so small as to lose the appearance of a naked runner with terminal rosette (Mr. Farrer stated that baldensis looks "from afar" like diapensioides), while those of the Kabschias (*e.g.*, Rocheliana) are so squeezed down like a closed concertina as to lose their columnar appearance and assume the general look of a full rosette. There are doubtless other distinguishing marks of cæsia—its more wiry stem, the purity of its whiteness, the nearness of its lower leaves to the general Kabschia spininess, its linear stem leaves, the absence of Aizoon's curved and saw-like teeth, and the tendency towards a corymbose rather than racemose cyme. But some or other of the usual Aizoon characteristics may be evanescent in so minute a species as baldensis.—E. ENEVER TODD.

A CHINESE LILY.

SIR,—I am enclosing a photograph of Lilium giganteum yunnanense in the hope that it will interest readers of THE GARDEN. It has flowered with us this year, and as one can gather from the illustration the blooms are shapely and of good size. It is very handsome with its tall erect spikes.—E. BERKELEY.



LILIUM GIGANTEUM YUNNANENSE.

A MAGENTA BORDER.

SIR,—I was interested to read in the number following that in which there was an appreciation of Gladiolus byzantinus (July 26th, page 520), an article on magenta flowers (August 2nd, page v). There is a very old clump of G. byzantinus in a sunny corner of our kitchen garden and I was wondering whether or not it would stand removal to a border facing north-west, when I read in THE GARDEN about its hardy constitution and decided to risk it. No two people agree as to what is magenta, but G. byzantinus seems to me a very good example of one tone of it, and it is going into what for two years I have called my magenta border. Here I segregate all those old-fashioned things which when mixed with warmer-blooded neighbours set them quarrelling at once. Agrostemma coronaria, sometimes so aggressive, is happy here, Dicentra spectabilis dangles its bleeding hearts, Lupinus roseus (which we like better than many new kinds, and which here can "blue" unresented), harmonises with irises Queen of May and Mme. Pacquitte, and with real magenta double pyrethrums with names unfortunately long lost. Following these come English irises of several tones of purple-red, galegas common and G. Hartlandii, Lavatera Olbia, which looks so out-of-sorts in other company, and a little old geranium which I suppose is Endressi and almost exactly matches the lavatera in a huge cushion of bloom at the other end in front. (This goes on from May to November. One is ungrateful enough to get tired of it.) Poterium obtusum is feathery and pretty. Phlox le Mahdi looks well behind P. Jules Sandeau and Armeria Bee's Ruby edges some bits, while there is a long drift of Sedum spectabile and another of S. spectabile atropurpureum which, tidy all summer, will soon be a sheet of colour. Seen altogether one wonders where magenta ends and rose begins. Across a low corner ramps Acanthus mollis, every chance-sown 1921 seedling full of exuberant life; handsome though it is, it must be reduced or it will possess the border. There will be a variety of Japanese anemones out before very long, Mont Rose, a semi-double dwarf, in the van, and later on Michaelmas Daisies Lil Fardell and Ethel Ballard and others and some hardy chrysanthemums left all winter and summer, too, but Senecio pulcher, a magenta beauty for the front row, I lost last winter and must try to replace. I do not know if it is best planted in autumn or spring. I also badly want a magenta single hollyhock. My border sounds duller than it looks—its prosaic inmates make fine masses. I am counting on the Burning Bush to make a real bush near the front in time; Achillea ptarmica and gypsophila form two or three clumps, and Hyacinthus candicans comes up late through the leaves of Lupinus roseus. I want much more: Incarvilleas, sidalceas, viscarias, lythrums, Erigeron Elsie and Papaver Mrs. Stobart (a piece of extravagance which will probably be its own punishment by not harmonising with the rest), are all to go in this autumn. But meantime I am delighted to see THE GARDEN championing the long-despised magenta.—(Lady) E. HUNTINGFIELD

TIGRIDIAS AND WATSONIAS.

SIR,—If "Fanham's" garden is situated in a reasonably mild district and on well drained soil he should find little difficulty in growing tigridias. In really favoured districts the bulbs may be left in the open ground, but in most places it is necessary to lift them about November and store them in sand in a frost-proof shed until planting time comes round again in March. I find they succeed much better when left in the ground and soon form large clumps, but I doubt if this method would

answer in the Midland or Home Counties —certainly not on heavy soils. I also find that bulbs raised from seed are much more vigorous and hardy than imported and dried bulbs; in fine autumns it is easy to gather a quantity of ripe seed, which should be sown in a cold frame early in spring. The little seedlings grow quickly and will flower in the second summer after seed sowing. If the seed has been saved from a mixed bed of tigridias, the resulting plants often show the result of cross-fertilisation between the scarlet and yellow varieties. Tigridias certainly enjoy plenty of moisture, while in full growth, but at the same time must have exposure to as much sunshine as possible in order to thoroughly ripen the bulbs. A light mulch of stable manure is appreciated after the foliage is well above the soil (about the end of May). The only watsonia I have tried so far is W. Arderneі, the white bugle lily of South Africa. In this mild district it is quite hardy and increases fairly rapidly at the root. In the hot summer of 1921 I saved ripe seeds and raised a number of young plants from them. As this watsonia is an evergreen plant, it naturally prefers to be left outdoors, but where severe frosts are experienced it must be lifted and treated like a gladiolus. As the foliage makes a good deal of growth very early in spring and the flower-stems appear in April, it should be given a sheltered situation; my plants are growing among Azalea mollis and seem to revel in the rich loam and peat of this bed. Plants which have been lifted and stored flower much later in the summer and do not grow so tall. If "Fanham" will send me his address I shall be glad to send him some tigridia seed when ripe in the autumn.—N. G. HADDEN, *West Porlock, Somerset.*

SUMMER BORDERS.

SIR,—When I read Miss Jekyll's article on "Summer Borders" in your issue of July 19th, I promptly wrote this criticism. But I hesitate to send it even now as I quite realise the impertinence of criticising such an authority. Miss Jekyll evidently has in mind a large garden—only a large garden can have "special borders for the various seasons." If that is admitted then there is room for various borders or beds—a flowering shrub bed, a herbaceous border, a rose garden, a wild garden. Take her May-June border. Peonies and columbines for the flower or herbaceous border surely—columbines are really alpines. Olearia and deutzia to the flowering shrubs, foxgloves to the wild garden. Iris, broom, and helianthemums admittedly are intermediate and interchangeable. But do they all flower in May-June? Our peonies and columbines are, of course, long since over, but the foxgloves and deutzia are now at their best and olearia has not yet flowered. Then her June border—Guelder rose, Heuchera Richardsoni and China rose in one border—privet and Nepeta Mussini, along with irises and more China roses. Nor would I mix delphinium and anchusa with Phlomis fruticosa if I could afford to keep them separate. I am quite sure Miss Jekyll would never mix old oak, Chippendale and Louis XIV, or, shall we say, Rembrandts, Zorn etchings and Hokusias, each beautiful in its proper place. If I had only one cupboard I would have to put Crown Derby along with Chinese porcelain—having two I prefer to show them separately.—D. DOUGLAS OGILVIE.

GOOSEBERRY SAW-FLY.

SIR,—I constantly see in THE GARDEN articles about destroying the gooseberry saw-fly. We never now have the gooseberry caterpillar in this garden, because my father, Mr. Spencer Bickham, always has three broad beans sown between each gooseberry bush, and apparently the saw-fly does not like the smell of the beans. Whatever the reason the fly never attacked our gooseberry bushes except one season, during the war, when the temporary gardener forgot to carry out my father's orders as to sowing the beans. The bushes were then stripped by the caterpillar. I think this very curious fact ought to be more widely known, hence this letter.—CONSTANCE BICKHAM, *Herefordshire.*

RHUS COTINUS.

SIR,—In writing to the Curator of Kew Gardens as to a rather fine shrub which I have in my garden at Lindfield, near Haywards Heath, Sussex, *i.e.*, Rhus Cotinus, (the Venetian Sumach), he advised me to have a photograph taken of it and send it to THE GARDEN, as it might be of interest to your readers. The shrub is nearly 9ft. high by about 12ft. across and until recently was in the most marvellous condition of bloom, the whole of the upper part being covered

THE VENETIAN SUMACH, RHUS COTINUS.

with a magnificent filigree red web; but, unfortunately, though still beautiful with the bloom, much of this has been washed off by the recent rains.—J. R. COOPER.

THE FLOWERING OF HOLLIES.

SIR,—As an old reader of THE GARDEN, I am always interested in all its correspondence. Therefore I am prompted to give a few thoughts on the subject mentioned. Very rarely during the past fifty years have I seen so much holly bloom as at the present season, both types being very abundant. In my garden and on all trees in hedgerows in the neighbourhood of Hurworth-on-Tees, there are twigs with full set berries from 8ins. to 10ins. in length, in a most vigorous and healthy condition, all seeming to bespeak a promise of winter colour. My apprenticeship was served in a garden where a very fine collection of all types of silver, golden and green-leaved hollies were a special feature. Each alternate year there were so many trees set apart to be mulched with the best material at disposal, and the thorough way in which the work was carried out made an impression on my mind, which, although it is fifty years ago, taught me that if culture is to be a success in any branch of gardening craft, unless it is thorough in every way, results are not seen which should mean satisfaction. The procedure was as follows; a circular space, as large as the nearness of other plants would allow, was taken out, then a thorough forking up as deep as possible given, and a great flood of liquid stimulant; then, after allowing for a perfect saturation, the mulch was put on and covered, and when each set of trees had been treated, the general putting in order of the surroundings was completed. The next set followed in succeeding years. As a youth, I used to await each week-end for my paper and although fifty years have passed since then, I still await with even greater interest THE GARDEN, which in its newer form is still of as much or even more interest.—VICTOR H. LUCAS.

NEW ZEALAND ALPINES.

SIR,—So many people have written to me showing kindly interest in my little notes on New Zealand alpines that perhaps a few more will be acceptable. Our southern alps, once past the foot hills, which are covered with yellow tussocks—beech bush (Nothofagus), scrub (Leptospermum scoparium), etc.—are mostly bare gaunt rocky giants, snowclad for eight months of the year. The taller ones farther back have perpetual snow and glaciers. The ones I am writing of are the bare steep ones covered in shingle slips and rocks. Anyone looking casually at these slips would say no vegetation grew there at all. On close examination and far apart from one another are quite a lot of plants and all of them of interest. Raoulia eximia (the vegetable sheep) has large cushions lying on the outskirts of the rocks, sheep colour and really like sheep lying down, some cushions as big as three sheep close together. Then Raoulia mammalaris, a near relation but which never grows into big sheep, seldom larger than a fair-sized old-fashioned pin cushion. This, too, prefers rocks to shingle. Again, another relation, though distant, our edelweiss (Helichrysum grandiceps), a beautiful species, also preferring rocks to shingle. Some of the celmisias like a bare mountain too, but not the large-flowered ones. They prefer a little soil and more company. Celmisia laricifolia is a tiny little grey plant (larch-like leaves, as the name suggests, and a neat little daisy to match), quite a gem to tiny plant lovers. Celmisia discolor and C. viscosa do grow in companies, gradually spreading into large patches of rosettes, and they are the exception in that they can be seen from a distance, as they have rather more colour in their stiff, broad-pointed yet stumpy leaves, as well as growing into quite large patches, daisy flowers, white. C. discolor has sticky stems and pretty sticky bracts under the sepals.

Then come the pure shingle lovers. I started this description at the top of a 6,000ft. mountain (Mt. Todesie, Canterbury, New Zealand) and am gradually coming down. We are now about 4,000ft. up. Ranunculus Haastii, a plant with one cut fleshy leaf, sometimes two, but not often, and a stem bearing one large yellow blossom. Then comes a cotula, C. pyrethrefolia. The flowers are like a red button with a few little red pins in it, a dull ugly red, and the leaves like a pyrethrum, as the name implies. Lobelia Moughii, a true lobelia, like our garden "Chystal Pallace," only looser and larger in foliage. The flowers I have never seen, and in my "Plants of New Zealand" it is only referred to as "remarkable." Lower still comes a tough little cress with erect heads of white blossom about the size of Cheiranthus Allioni, and Stellaria Moughii, a limp little grey plant belonging to the chickweed family. Again lower still, 3,000ft., come the curious penwiper plants (Notothlaspi rosolutum), with their fawn-coloured ultra sweet-scented blossoms; and the last a parsnip, Ligusticum camosulum. This is so particular about being sure of keeping its head above shingle that it creeps under the shingle and only allows its tuft of leaves to grow when a reasonably firm foundation of shingle is found. It will travel a yard underground to find a good place. All these plants are grey or stone colour, except for the two celmisias mentioned, and it is only anyone really interested that would find anything at all.—MARY POULTON.

THE LATE MR. ANTHONY WATERER

HORTICULTURE has lost a striking and in some ways unique figure by the death of Mr. Anthony Waterer, which took place on July 24th last. In these days rhododendrons loom somewhat largely in the public eye, chiefly through the exploration of the west of China and Tibet, which has brought into cultivation an enormous number of new species. But previous to the journeys of Wilson, Forrest, Farrer and Ward in those far-off lands, no name was more closely associated with the word rhododendron than that of Waterer. To the various members of this family gardens chiefly owe the wonderful race of hardy hybrids which long have filled, and long will continue to fill, a very important place in horticulture. Compared with many of the new species, the Waterer hybrids, especially the earlier ones, may lack distinction and refinement, but they are easily grown, very hardy, and scarcely ever fail to give gorgeous displays of colour in May and June. They never let one down, and except in the warmer parts of our islands, so much cannot be said of the others.

In the development of this race the late Anthony Waterer played a very worthy part. He was in his seventy-fourth year when he died, and except for a short period spent in France and Germany in his youth his life was passed in the Knaphill Nursery, near Woking. He was the second of the name, the first Anthony being a remarkable man, many of whose qualities and characteristics his son inherited. Indeed so alike were they, that, to one like myself who knew both of them well, it is difficult to dissociate them. Both were often blunt in manner, not excelling in the arts of politeness, but of sterling integrity. Before the war there was no nursery in existence from which one could rely on getting better stuff than from Knaphill. The elder Anthony acquired and left his son a very considerable fortune, but neither departed from the plain comfort and homely living of their early days. Both were keen sportsmen, lovers of horses and cattle, interested in cricket and racing. Sometimes the best new rhododendron of the year was named after the winner of the Derby, the race coinciding as a rule with the zenith of the rhododendron season.

Latterly, Mr. Waterer devoted more of his personal attention to hardy azaleas than to the evergreen rhododendrons, and he produced some very fine hybrids, especially in brilliant reds and yellows, which, when they get into general commerce, will add much to the beauty of the azalea season. So near were they to his heart that he did not care to part with them except to specially favourite customers. A story connected with these azaleas—which I know to be true, because an acquaintance of mine was, with Anthony, the chief actor—is perhaps worth telling. My friend was not quite one of the *personæ gratæ* just mentioned, but being of considerable importance in the gardening world was taken to the spot where were congregated the very cream of the Knaphill azaleas—the stud collection—in full blossom. After duly admiring them, he said: "I'll take two dozen of those, Mr. Waterer." I am not quite sure whether his idea was to give what he thought would be a welcome order or whether he was merely "trying it on," but he was rather taken aback by the reply: "I'm damned if you do." It certainly lacked nothing in the way of directness, but scarcely suggested the atmosphere and tone of—well, say, a draper's shop.

With all his bluffness, Mr. Waterer was somewhat shy and, except with his intimate acquaintances, retiring in manner. He was very rarely seen at exhibitions or horticultural meetings. And he never married. B.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Lettuce.—A liberal sowing of lettuce should be made during the present month, choosing such varieties as All the Year Round and black-seeded Bath Cos. Sow in lines 1ft. apart, and when the seedlings are large enough transfer a quantity to a sheltered border, leaving the remainder in the seed bed until the spring. By doing this a succession of fine lettuces will be maintained.

FRUITS UNDER GLASS.

Strawberries.—To be successful with strawberries in pots it is very necessary to have healthy, vigorous plants, and it pays to secure a new stock every few years. New runners should be planted in lines 2ft. apart in an open situation, and next year they will produce strong runners for pot work if the flowers are removed. In any case a small bed should be planted, and set aside for producing runners next year. After these are secured a fine crop of fruit will be gathered in the open the following season.

The Orchard House.—Trees in this house from which the fruit has been gathered may be placed in the open, but it will be necessary to well protect the roots by plunging the pots in ashes and affording copious supplies of water. A mulch of decayed manure will lessen the quantity of water required, and assist the roots of the trees. Where the trees are left in the house the roots should be fed with liquid manure and the ventilators opened to their fullest extent. Fruit trees occasionally cast or drop their buds later on, and this is often brought about by the roots being allowed to become dry at this period. Continue to syringe the foliage each afternoon when the weather is fine, and care should be taken to prevent dryness at the roots. The soil is often damp on the surface, but dry beneath, hence the necessity of close observation.

THE HARDY FRUIT GARDEN.

The Fruit Room.—It is advisable to give the fruit room a thorough cleansing at this season in readiness for the crops to be stored later on. Stages should be scrubbed, walls limewashed and afterwards plenty of air admitted for several days.

Young Trees.—Attention should be given to the training of young trees, especially espaliers and those on walls. At this season the work is more easily accomplished than when the wood is ripe.

FLOWER GARDEN.

Propagation.—Where zonal pelargoniums are used for bedding purposes, the time has arrived for taking cuttings to furnish plants for next season. Cuttings of the popular Paul Crampel are best rooted in pots 3ins. in diameter; the soil should contain a proportion of sand and four or five cuttings may be placed in each receptacle. When the cuttings have been trimmed, they should be allowed to dry for a few hours before being set in the soil. This applies to all the sappy varieties, but not the ivy-leaved section. Such as Mme. Crousse and C. Turner can be placed in boxes as they are not so liable to damp off during the winter months. The cuttings will readily form roots outside, or on a shelf in the greenhouse. Keep the soil just moist and remove flower buds and dead leaves as they appear.

Sweet Peas.—Unless it is intended to save seeds, the pods should be removed every two or three days. An occasional dose of weak liquid manure may be given, and the soil between the rows ought to be hoed at intervals to prevent the ground cracking.

T. W. BRISCOE
(Gardener to W. R. Lysaght Esq.),
Castleford, Chepstow, Gloucestershire

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Brassicas.—The time is near at hand when the seed of Brussels sprouts, borecole, cabbages, cauliflowers and savoys should be sown, so that early plants will be available for planting out in April of next year. It is always safe to follow this old rule as often—and we may take the present year as an example—vegetation is late; but when plants are set out in April they have a longer period in which to grow, and so have more chance of maturing than those raised from seed sown outside in spring.

THE FLOWER GARDEN.

Calceolaria amplexicaulis.—This old lemon-coloured calceolaria is still used for bedding, and those who require dot plants for next year should pot up now any spare plants which have been left in boxes or frames. Pinch out the growing point of each shoot so that bushy plants will be obtained.

Geraniums.—Those who still retain the bedding geranium should secure a few cuttings and insert them in boxes in sandy soil which has been made very firm. Cuttings taken at this time should be procured in such a way that the appearance of the plants and the beds from which they are taken is not destroyed.

Pentstemons.—There is no doubt that the best way to get a good display from pentstemons is to allow the plants to remain in the ground, as two year old plants are very effective when in flower. Cuttings may be inserted in cold frames from now onwards.

Roses.—All who wish to avoid being troubled with suckers and desire to increase their stock of climbing plants, should insert cuttings now in somewhat sandy soil out of doors. Rambler roses of the Wichuraiana section, such as Dorothy Perkins, Hiawatha and Lady Gay, can easily be propagated by cuttings.

THE HARDY FRUIT GARDEN.

Plums.—Where the fruits are showing signs of ripening on trees growing on walls, nets should be hung up in front of them. In the case of large standard trees bearing heavy crops, it may be found necessary to support the lower branches with props. As soon as the fruits show a little colour, quantities should be pulled. These fruits will ripen and colour splendidly if spread out in shallow trays and set on shelves in any of the glasshouses. This thinning will not only relieve the trees, but it will secure the fruits from being damaged by birds, as it is not always practical to try to place nets over large and spreading trees.

Raspberries.—As soon as the crops have been secured and the plants cleared, the old canes should be cut out, then collected into bundles and burned. In places where they are likely to get broken, the young growths should be loosely tied to the wires

FRUITS UNDER GLASS.

Vines.—When the bunches have been cut from the early house the vines should be half pruned; and if red spider shows anywhere about, spray the foliage, etc., with one or other of the approved insecticides. In the late house the soil moisture can be conserved by placing a good layer of clean straw all over the surface.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Bulbs for Forcing.—With bulbs used for forcing purposes it is important that they be potted early, for success depends very largely on their being well rooted before they are used for forcing. Roman hyacinths and paper white narcissi, so useful for flowering at Christmas, should be potted up during August. Also Dutch hyacinths that are now specially prepared for forcing. Roman hyacinths may be grown in pots or boxes, placing five bulbs in a 5in. pot; when grown in shallow seed boxes they are very useful, as they can be lifted from the boxes when in flower and used for making up bowls and other suitable receptacles. The early Duc van Thol tulips are very useful when grown in the same way. Paper white narcissi will require 7in. or 8in. pots, and four or five bulbs, according to size, may be placed in a pot; the same applies to other narcissi used for pot culture. The large-sized Dutch hyacinths should be grown singly in 48-sized pots, and the bulbs just covered, the tip of them showing through the soil. Early-flowering narcissi, such as Golden Spur and Henry Irving should be used for forcing purposes. N. Poeticus var. ornatus, is very useful for pot work and proves valuable at Easter when white flowers are in demand. After potting, the pots should be stood out in an open position, or at the foot of a wall, and then covered over with ashes or fibre. This conserves moisture and does away with the necessity of frequent watering. They may remain under the ashes until they are well rooted and growth is just showing on the top of the pots, when they should be removed from the ashes and placed in cold frames until such time as they are required for forcing purposes; a frame with a north exposure is very suitable for this purpose. When in the ashes or fibre they should be examined from time to time, and removed before they commence to grow up through the covering material; any that be neglected in this respect should be kept shaded for a few days until they are hardened to the light. The ordinary large-flowered crocuses, of which there are so many beautiful varieties, are very useful, especially for the small unheated greenhouse. It is very important for success with them that they be grown perfectly cool; any attempt to force them will result in failure, as they go blind and the flowers are aborted. They may be grown in 48-sized pots, shallow pans or in bowls of fibre, for which latter purpose they are very suitable. After potting they should be stood outdoors and be covered with ashes, as advised for the larger bulbs. All the spring-flowering species of crocus are very suitable for growing in small pots or pans in the small, unheated greenhouse. Some of them are, of course, scarce and expensive; there are, however, quite a number of species and varieties that are quite reasonable in price, such as CC. biflorus, etruscus, Imperati, Sieberi, Tomasinianus and versicolor. Lilium candidum is very suitable, and might be more frequently used, for pot culture. Where it is intended to grow this lily pots, it is important that the bulb should be potted during August, as L. candidum starts to grow early, and the longer the bulbs are kept dry the less chance they will have of succeeding. Three or four bulbs according to size may be placed in an 8in. pot. The potting compost should consist of a good medium loam, with enough sand to keep it open and porous, or old mortar rubble may be used instead as this lily is a lime lover. As this is not a stem-rooting lily it is unnecessary to cover the bulbs deeply, a covering of 2ins. being quite enough. As no top-dressing is necessary, the pots should be filled up when the bulbs are potted. After potting stand them out at the foot of a wall, but do not cover with ashes, though they may be plunged to the rim to conserve moisture and thus save watering. Success with this lily depends on giving it perfectly cool treatment at all times.

J. COUTTS.
Royal Botanic Gardens, Kew.

OBITUARY

R. A MALBY.

It is with regret that we announce the death of a talented contributor. Mr. Malby's fine and knowledgable photography gave delight and provoked admiration throughout the horticultural world. He journeyed to Manchester to attend the Lancashire Show, but he went there to die. He was stricken down with "flu" and pleurisy immediately on his arrival, and he passed away on the morning of August 7th. He was a splendid photographer. His black-and-white and his coloured pictures of flowers and gardens are world famous. He was a tireless worker and never spared himself. Often when many a man would have been in bed, or at any rate taking care of himself, "Father" was busy and at work. This was one part of the secret of his success. The other was his thoroughness, taught him by his father, to whom he dedicated his little book, "The Story of My Rock Garden." At his house at Woodford his ingenuity turned what might have been under many owners a humdrum back garden into a delightful home for alpine and rock plants. His Swiss journeys and his love of flowers brought this about. Our heartfelt sympathy goes out to his widow and her five young children. All must now be so different from what was anticipated: A move to Cuffley to get better light for his work in winter, and a new and larger house and appurtenances to suit the increasing volume of his orders. Cuffley was a milestone in his life and tells its tale. He will never pass another and horticulture will be the loser. *Hinc illæ lacrimæ!*

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Lupins Unsatisfactory (B. T. D. S.).—Sometimes these plants are adversely affected, when newly planted, by severe frosts which stunt their growth during the following summer. When well established severe weather does not affect the plants so much. Evidently there is some ingredient in the border that the plants do not like and it would be more satisfactory to grow them in that part of the garden where the others do so well.

TREES AND SHRUBS

Hard-pruning Rhododendrons (R. G. B.).—The end of April is a good time for this work. If short spurs of the old wood are left, young shoots usually push out freely. Tar over the cut surfaces. Syringe the stems if the weather happens to be dry or spray with a garden engine.

Climbers for South-East Scotland (N. Y.).—Clematis Jackmani superba, darker than the type, and Gipsy Queen, dark velvety purple, should meet our correspondent's requirements. They would thrive on the west side of the house, and probably also on the north side. The Virginian creepers do well in all aspects. Jasminum nudiflorum will be found to flower even better facing west than south. Clematis montana and the var. rubens should succeed on the east side. Cydonia japonica would be better on the west side in preference to the east, as it blooms early in the year. As additional climbers with blue flowers try Ceanothus thrysoideus and C. Gloire de Versailles on a sheltered west wall. They might succeed, at least we suggest the experiment is worth while. Also try the tall, loose-growing form of Forsythia suspensa on a south or west wall. The golden-yellow flowers are delightful in early spring. A useful tall evergreen shrub for partial shade is Ligustrum lucidum.

THE GREENHOUSE.

Climber for Small Greenhouse (R. J. W.).—As the position for the climber seems to be up against the wall of the house, a camellia would be very suitable. Camellias are hardy and would stand the draught very well, and, of course, are evergreen. Preference should be given to some of the beautiful single varieties, such as Mrs. Saunders, white; magnoliæflora, shell pink and very distinct; or Lady Clare, salmon rose. Rhyncospermum (Trachelospermum) jasminoides is a neat evergreen climber with small sweet-scented flowers. Hibbertia dentata is also a beautiful evergreen climber with yellow flowers which are produced over a long period.

THE ROSE GARDEN.

About Roses and Romneya Coulteri (Miss B. B. R.).—The following would be suitable roses for the position, the lightness of the soil can be improved by surface dressings of heavy loam. Caroline Testout, Covent Garden, J. B. Clark, Mrs. J. Laing, General McArthur, La Tosca, Mrs. Millar, Ophelia, Snow Queen, Pharisaer, Hugh Dickson and Lady Hillingdon. Without seeing the insects referred to, we can only suggest that the holes in the leaves of Romneya Coulteri were made by the shot beetle, not for food for itself, but for storing in the tunnels of the harder wood of trees to coagulate for food for their maggots.

MISCELLANEOUS.

About Mice (E. H. P.).—The bulbs may be moistened and then covered with red lead, dusting on the red powder thinly. To trap the mice smear some fat—mutton-fat for preference—inside some glass jam jars, just under the shoulder of each jar and about one and a half inches from the top. Bury the jars in the soil, level with the surface, the mice will try to reach the fat, overbalance, and fall into the water which should rather more than half fill the jar.

Names of Plants.—(A. F. N.).—Platycodon grandiflorum, a hardy perennial which will thrive in any border.——(J. M. B.).—Trachelium cœruleum.——(X. Y. Z., Birmingham).—1, Artemisia pontica; 2, Poterium officinale; 3, Asplenium Felix-fœmina congestum; 4, Asplenium Filix-fœmina cristatum.——(W. McN.).—1, Pseudotsuga Douglasii; 2, Abies pectinata; 3, Abies Nordmanniana; 4, Lactuca macrophylla: 5, Thalictrum minus; 6, Potentilla argyrophylla atrosanguinea; 7, Spiræa kamtschatica: 8, Serratula coronata.——(J. R.).—Eucalyptus Muelleri.——(G. A.).—Probably Hemerocallis fulva. Flowers withered on arrival; please send another specimen.——W. W.—Jacobinia carnea.

THE SIX BEST HYBRID TEA ROSES?

NO doubt this is a question which puzzles everybody who has a garden; it is also one which THE GARDEN is frequently asked, and which is exceedingly difficult to answer. In order to give a satisfactory list of the most popular Six Hybrid Teas, it would be necessary to travel the length and breadth of the British Isles and to enquire of every gardener. This is obviously an impossibility, so we are asking our readers to vote on this most important subject, so that they may choose by popular vote what are the six best varieties. Roses, like many other plants, increase in the number of varieties year by year, and this naturally makes the selection of three or four kinds for a rose bed rather a problem. It is to help our readers that this competition is being held. One individual's judgment may not always be correct, but the preference of the readers of THE GARDEN will carry great weight. It may also occasion readers to discuss the matter with their gardening friends, and in many cases their friends' replies may surprise them, for opinions on the merits of roses are as divided as upon many other garden flowers.

RULES.

¶ A list of six (only) hybrid tea roses to be sent in in order of preference on a separate sheet of paper, with name and address of sender clearly written on the top. NO ALTERNATIVES WILL BE ALLOWED, but readers may send in any number of lists, provided that a coupon (see next paragraph) is sent in with each list.

¶ Lists must reach this office not later than Saturday, September 20th (after that date no lists will be accepted) and must be accompanied by a coupon, which will be found on page v. of this issue. Coupons will also be found in the issues of August 30th, September 6th and September 13th.

¶ The popular vote will be final, and no correspondence will be entered into over this competition.

¶ Envelopes must be marked COMPETITION and addressed to THE GARDEN, 20, Tavistock Street, Covent Garden, W.C.2.

¶ The Editor will not be held responsible for letters missing in the post.

¶ The First Prize will be an order for £3 on any advertiser to be found in the pages of THE GARDEN.
The Second Prize will be an order for £2 on any advertiser to be found in the pages of THE GARDEN.
The Third Prize will be a book, or books, from the *Country Life* Library to the value of £1.

¶ The result will be announced in THE GARDEN in the issue of October 11th.

¶ The Editor's decision on all points will be final.

Readers of THE GARDEN should make a point when visiting London of looking at the books published by *Country Life*, which are on view at their showrooms at 20, Tavistock Street, Covent Garden, W.C.2.

In addition to their well known volumes dealing with gardening and horticulture, *Country Life* publish numerous books on Architecture, Furniture, Decoration, Housing, Sport, and Natural History.

IN OUR NEXT ISSUE WILL BE FOUND:

THE POSSIBILITIES OF GARDENING IN SCOTLAND, by Sir John Stirling Maxwell, Bt.

THE GARDEN AT LOGAN, WIGTOWNSHIRE.

ROSES FOR LATE SUMMER, by Laurence Cook.

THE CULTIVATION OF MUSHROOMS.

SOME OF THE BEST OF THE SAXIFRAGES

THE ROCKFOILS, AS A GENUS, ARE EXTENSIVE, AND THEY EASILY SURPASS ALL OTHER FAMILIES IN THEIR VALUE FOR THE ADORNMENT OF THE ROCK GARDEN.

THIS extensive genus contains so many species and varied forms that to a beginner making a selection it may appear a most difficult task. The object of the following notes is to suggest such a selection, and enumerate the best kinds for growing. The various members are adapted for many and diverse conditions, ranging from bog plants to those that will flourish in the smallest crevice in a rocky wall. For intermediate positions in the rock garden the beautiful kinds are numerous and generally are easy to grow, while others are ornamental plants for the border or spring bedding.

Commencing with the earlier flowering kinds, we naturally begin with Burser's saxifrage, S. Burseriana, a member of the cushion, or Kabschia section. This charming species is probably one of the most popular kinds in this group, opening its beautiful flowers in early spring when planted in a sheltered spot. It is an extremely variable plant both in foliage and flowers, and many so-called varieties have been given fancy names. For practical purposes the varieties may be reduced to three, the typical plant with tufts of spiny glaucous foliage, bearing single white flowers on stems 2ins. high in March. With broader leaves, var. major (which includes Gloria, magna, grandiflora and others), produces its much larger flowers often in February. Later on in April comes var. macrantha with pretty white flowers on red-tinged stems. In addition to the above there is a beautiful yellow-flowered form now in cultivation. Others of this group worth growing include S. cæsia, one of the smallest kinds with tufts of silvery leaves and creamy white flowers in June. A rich yellow flower is produced by S. Ferdinandi Coburgi, a Macedonian plant, while in S. marginata we have one of the best of the early-flowering white kinds. It is an Italian plant with small oblong leaves dotted on the margin with a series of lime pits which gives the whole plant a grey appearance. Closely allied is the smaller S. Rocheliana, with white flowers, two to four in a head in April. One of the most useful in the rock garden is S. sancta, with its broad carpets of dark green foliage, studded in early spring with rich orange flowers. There are numerous hybrids in this section, many of great beauty, among which may be mentioned the yellow-flowered apiculata, Boydii, Faldonside, Haagei and Paulinæ, and the white-flowered bursiculata, Jenksinii (S. Boydii alba), Obristii, Petraschii and Sundermanni. A pretty rose tinted form is S. Irvingii, of very neat habit and a good grower, while later productions with deeper coloured flowers are Mira, Mrs. H. Mosshall and Jenkinsiæ, among others.

A most important group is known as the encrusted or silvery rockfoils, consisting of over a dozen species and very numerous varieties, as the various kinds hybridise very freely. These form the summer-flowering section of the family and for bold effect are very valuable in the rock garden. One of the most variable species is S. Aizoon, due partly to its wide distribution over the mountains of Europe and elsewhere. There are some forms with very small rosettes like var. baldensis, while others approach in size those of S. Hostii, with strap-shaped leaves and much taller sprays of white flowers. In colour the flowers vary from pure white, var. Rex, to yellow, var. flavescens, while in var. balcana the white petals are heavily spotted with pink. A choice species is S. catalaunica, with recurved leaves having a broad silvery margin, the white flowers of which are produced in loose elegant panicles in May. There is no more graceful plant than S. cochlearis, which may be described as one of the neatest of this group. It has small rosettes of silvery spoon-shaped leaves, packed closely together, and forming a dense cushion. The pure white flowers in elegant panicles are produced freely in early summer. Known by its rosettes of broad green leaves, S. Cotyledon is one of the most distinct as well as one of the most varied. It is found widely distributed over the mountain chains of Europe, always growing on granite. The largest form is known as S. Cotyledon var. icelandica. The type has short, broad leaves, and the panicles of white flowers only occupy the upper half of the stem. In var. pyramidalis the stem is branched to the base and the white flowers are spotted with pink. With pink flowers is the distinct S. Kolenatiana from Asia Minor, one of the best forms of which is known as S. Sendtneri. Very handsome plants are S. lingulata and its various forms, of which three may be mentioned here, var. Bellardii has long, linear leaves, more or less erect and produces a very handsome inflorescence of white flowers in May. Var. lantoscana, like the above is found in the Maritime Alps, and is known by its short and blunt reflexed leaves, more or less convex on the upper surface. It has an arching inflorescence with all the flowers crowded on the upper surface. Var. australis from Italy has longer and broader leaves, with longer sprays of flowers. The most striking member of this group is S. longifolia from the Pyreenes, with large rosettes of silver-edged leaves and handsome pyramids of white flowers, often two feet or more in length. The beautiful rosettes are often many years in attaining the flowering stage, but after flowering and producing seed the plant dies. A distinct biennial is S. mutata with rosettes of broad leaves, and copper coloured flowers in July. It does best in half shade.

SAXIFRAGA LONGIFOLIA WITH ITS SILVER-EDGED ROSETTES AND HANDSOME PYRAMIDS OF WHITE FLOWERS.

The Mossy section contains many useful plants, suitable for the rock garden, spring bedding, and for the front of the herbaceous border. The beautiful green carpets of the Dovedale Moss (S. hypnoides), are very attractive at all times, with the additional feature that they are covered in spring with white flowers. One of the best and most useful of this group is S. Wallacei, with distinct foliage of a light green

Digitized by Google

SAXIFRAGES OF THE MOSSY SECTION FORM BEAUTIFUL GREEN CARPETS WHICH ARE ATTRACTIVE THROUGHOUT THE YEAR.

colour and large white flowers that are sweetly scented. S. trifurcata is an elegant plant from Northern Spain, with stiff three to five parted leaves of a glaucous hue, and graceful sprays of white flowers. One of the most varied is S. cæspitosa, which is found over the whole of the Northern and Arctic regions. It forms dense tufts of deep green foliage that spread rapidly and soon form large groups under favourable conditions. A very distinct form is var. hirta with hairy leaves, giving it a white, woolly appearance. S. decipiens is a strong-growing kind, in some forms of which the flowers are rich red, fading to pink. A very dwarf dense-growing kind is S. muscoides, with yellowish flowers, which forms a moss-like tuft only an inch or so in height. S. muscoides var. atropurpurea has bright red flowers, while there are many hybrids in this section with rich red flowers, including Guildford Seedling and S. decipiens var. sanguinea among others.

The Megasea section are remarkable for their handsome foliage and large trusses of beautiful flowers, S. cordifolia having large cordate leaves and rosy red flowers in April. S. ligulata is one of the earliest with pink flowers in March, while S. purpurascens and the closely allied S. Delavayi have deep purple flowers in May. They are all excellent for parts of the rock garden where their evergreen leaves are of much value in furnishing during the winter months.

We next come to the so-called Porphyrion group of which the best known member is S. oppositifolia. They are among the most beautiful of alpine plants and those who have seen them growing in their native habitats will not soon forget the sheets of colour they produce. S. oppositifolia is a native of this country, being found in Yorkshire and parts of Scotland. The flowers vary considerably in size, the finest and largest forms being found on the western Alps and Pyrenees. The type of this plant has bright purple flowers, and is of prostrate creeping habit, with long, wiry, leafy evergreen stems. The brightest form is var. splendens with purplish crimson flowers, while the largest is var. grandiflora. There are many other named varieties well worth growing including var. speciosa, var. latina and var. alba, with white flowers. S. retusa is a pretty, minute species with the habit of the above, and deep, rich ruby coloured flowers several in a head.

For the bog there is the yellow-flowered S. Hirculus and the prostrate-growing aizoides, in addition to the giant S. peltata, with its peltate leaves and large flat cymes of pink flowers on stems 3ft. to 4ft. high. The well known London Pride (S. umbrosa) with its rosettes of thick leathery leaves and light graceful sprays of pink-spotted flowers is very useful as an edging for the border and very attractive in the summer months, a closely allied species being S. Geum with more rounded leaves.

For flowering in the autumn we have the Japanese S. Fortunei, with large dark green leaves that are rounded in general outline, but lobed and toothed on the margins. The white flowers, having unequal petals, are borne in panicles on stems that reach to a height of 1ft. or more. It does best in a sheltered half-shady position, where it is protected from frost. One of the most distinct members of the family is S. Grisebachii, belonging to the Engleria group, with silvery leaves produced in handsome rosettes and stems rising to a height of 9ins. or more. At the top is a nodding inflorescence of purplish crimson flowers having yellow stamens. Other members of the red-flowered group are S. media, S. thessalica and S. Stribrnyi.

Hybrids are numerous, one of the most remarkable being one called "Tumbling Waters," a hybrid of S. longifolia and S. lantoscana, with long sprays of white flowers on stems up to 20ins. long. Dr. Ramsay is another beautiful plant with silver grey rosettes and plume-like arching sprays of white, pink-spotted flowers. In addition there are many others worth growing, but these are enough for a start.

CULTIVATION.

Included in the large saxifrage family are plants which may be grown in any position to be found in the garden. For the bog there is the giant Californian S. peltata, with its peltate leaves, as well as the low-growing S. Hirculus and S. aizoides. For moist, shady and half-shady places we have all those included in the Mossy section, such as S. muscoides, S. hypnoides, and the various forms of S. decipiens. S. Burseriana also is partial to shade, and frequently suffers through being planted in a sunny position. Other shade-loving plants are those of the London Pride group of which S. umbrosa is typical. For sunnier positions on rocky ledges there are many members of the Aizoon group, represented by S. lantoscana, S. Hostii and S. Cotyledon among others. S. apiculata, S. sancta and S. marginata may also be grown in open situations. For all the latter a well drained gritty soil is essential with plenty of lime rubble for the lime-loving kinds. Among those that resent lime are S. Burseriana, S. Grisebachii and S. florulenta. Seeds of all saxifrages should be sown as soon as ripe, in pots of gritty soil, and these should be placed in a shady frame or border with protection in the shape of glass against heavy rain. Cuttings may also be taken now, although

ONE OF THE NUMEROUS HYBRIDS IN THE KABSCHIIA SECTION. S. IRVINGII.

Digitized by Google

somewhat late. These may be inserted in almost pure sand and kept in a close frame till rooted. As there is no nutriment in the sand the rooted cuttings must be potted off as soon as possible.

LIST OF SAXIFRAGES FOR GENERAL USE.

YELLOW.—SS. aizoides, Aizoon lutea, apiculata, aspera bryoides, Borisii, Boydii, Elizabethæ, Faldonside, Ferdinandi Coburgi, Haagei, Hirculus, Kyrillii, muscoides, mutata, Paulinæ, sancta, Sibthorpii.

WHITE.—SS. Aizoon, Burseriana, cæsia, cæspitosa, catalaunica, cochlearis, Cotyledon, crustata, Dr. Ramsey, Fortunei, Geum, Hostii, hypnoides, Jenkinsii (Boydii alba), lingulata, lantoscana, longifolia, marginata, oppositifolia alba, Obristii, Petraschii, Rocheliana, rotundifolia, scardica obtusa, Stracheyi, Sundermanni, tricuspidata, trifurcata, Wallacei, Tumbling Waters.

RED, PURPLE OR PINK.—SS. aizoides atrorubens, Aizoon balcana, Aizoon rosea, Bertoloni, cartilaginea, Clarkei, cordifolia, crassifolia, decipiens grandiflora, d. sanguinea, Grisebachii, Kellereri, Irvingii, Kolenatiana, lilacina, Mira, ligulata, muscoides atropurpurea, Guildford Seedling, oppositifolia vars., peltata, purpurascens, umbrosa. W. I.

AMONG THE MOST BEAUTIFUL OF OUR ALPINE PLANTS IS S. OPPOSITIFOLIA.

GARDENING LAW

BY CHARLES GREENWOOD.

POISONOUS SPRAYS.

ONLY a few days ago a case was brought to my notice regarding the danger that might arise from the use of sprays containing poison. A man possessed a small garden bordered by fruit trees and adjoining a grass field. He sprayed his trees with a mixture containing a very small quantity of arsenic and a little of the spray blew over into the grass field. Three days later two of his neighbour's cows—which grazed in the field—were dead, and the unfortunate owner of the garden will be compelled to pay his neighbour about sixty pounds as compensation for the loss of the cows.

The lesson to be learnt from this is: Be very careful when using poison in gardens or orchards, for you are liable for any damage that may be caused by your carelessness.

ALLOTMENTS.

There must be hundreds of thousands of allotments in Britain at the present day, and allotment-holders will be interested to know that special laws have been passed to protect them.

For instance, if your landlord wants to obtain possession of your allotment, which is not *more* than forty poles in extent, and is cultivated mainly by yourself for the production of crops for your family, then he must give you at least six months' notice to quit. He cannot, at any time, turn you out between April 6th and September 29th.

A lot of tenancy agreements contain clauses which give the landlord power to get possession of the allotment if he wants it, for instance, for building purposes. Generally speaking, he must give you at least three months' notice to quit in these cases.

COMPENSATION.

If you have to leave your allotment because your landlord has given you notice to quit, whether the notice has been the ordinary six months' or the special three months' sort, then you are entitled to compensation.

This compensation is paid according to the value of the crops growing on the land when it is being cultivated in the ordinary way that an allotment usually is. It is also given for manure that has been applied to the land.

If you cannot agree with your landlord as to the amount of the compensation that should be paid, then you can apply to the judge of your County Court to appoint a valuator who will estimate what the compensation should be.

REMOVING TREES AND BUSHES.

As the tenant of an allotment you have the right, when your tenancy ends in the ordinary way, to remove any fruit trees and bushes and any fencing and other improvement that you have put up at your own expense.

This must be done before the notice to quit expires.

Care must be taken when you are doing this not to injure the allotment in any way, as you will be required to make good any damage that may be caused by the removal.

FLOWERS STOLEN OR DAMAGED.

There seems to be rather a general impression that it is not really theft to take flowers or fruit from somebody's garden.

It is true that special laws had to be passed to provide for such thefts, as it was once held that growing things were part of the land itself and were not capable of being stolen.

It is now, however, an offence to steal flowers or fruit under any circumstances, provided that they are of some value and cultivated.

Heavy punishments await hooligans who are caught while maliciously damaging flowers, plants or trees—a thing that some of these gentry seem to take a delight in doing.

OVERHANGING TREES.

There have been quite a lot of cases decided about overhanging trees.

You should be very careful not to plant yew or other trees which are poisonous where they are likely to overhang a garden or field belonging to someone else, as cows and horses seem to be attracted to their deadly leaves and eat them with fatal results—and you are held liable for the damage that has been caused.

There is another rather general impression that fruit hanging on branches that jut over property belonging to someone else belong to that person. That is not so, but if branches from somebody's trees overhang your garden, then you are entitled to cut them off yourself without giving any notice to the owner of the tree, no matter if the trees have been overhanging for twenty or thirty years.

If any damage has been done to your garden by the trees overhanging, then you have the right to sue the owner of the trees for the amount of damage caused by them.

The fact that the roots of a tree standing on other land have spread into your property does not give you a share in the tree, but you have the right to cut off those roots which are actually in your land.

SOME RECENT DEVELOPMENTS OF THE BEARDED IRIS

BY SIR ARTHUR HORT, BT.

(*Continued from page* 550.)

IT will be seen that such success as I have had in raising new forms has been due partly to design, but quite as often to the chance action of the bees. Other hybridisers, such as Mr. Bliss, have worked systematically on Mendelian lines, aiming at a definite result. Far be it from me to depreciate such scientific work: in my own case leisure has generally been wanting, but I fear that I have also enjoyed a more gambling method. During the war I had no time to pollinate flowers, but contented myself with sowing seed fertilised by my neighbours' bees; and, as I never can bring myself to protect buds from the bees with muslin bags, I cannot always be certain that the result obtained even from flowers artificially pollinated is what I intended. At all events, I can heartily recommend to anyone who has not time or inclination to make deliberate crosses the pastime of raising plants from seed of kinds recognised as good seed-bearers. If to start with you have a fair variety of kinds growing together, the bees may be trusted to mix them up. The seed of a garden hybrid may give a more robust, or otherwise improved, form of the parent. Thus, I have seedlings, children and grandchildren, of Queen of May, in favour of which I have discarded the old Queen herself; and Alcazar is producing notable seedlings in several gardens known to me.

If one grows irises of this class from seed, it becomes before long a problem what to do with all the seedlings. Supposing there are twenty seeds in a pod and they all germinate, you will have twenty distinct plants, no two of them quite alike in flower. I divide them into three classes—those worthy of a name as distinctly new forms, those worth keeping but not distinct enough to name, and those which had better be destroyed. It is, of course, the second class which gives the trouble, especially if one has but limited space and labour at command. If space can be found, a patch of seedling-forms much alike in general character, but showing the sort of gradation which you see (say) in a wood of wild daffodils, has a charm of its own. Moreover, such things make useful presents to people who have just heard about irises, but are not so particular as to "points" as those who have been in the habit of looking at them with a raiser's eye. You can tell them to assign what names they please, and flatter them with the assurance that they have got what no one else possesses!

I have spoken of "points," and so had better say what are the points which I specially look out for in a new plant. As to colour, nothing muddy or muddly will do: I like *either* a self-coloured flower, or *else* a strong contrast between standard and fall. As to shape, I find I get increasingly particular. Some wild flowers with standards which readily flop or break, such as Amas and Kharput, are nevertheless indispensable; but in a hybrid I incline to insist on standards which hold themselves erect, whether meeting at the points or standing up well apart, and falls which do not "buckle" round the stem. Thus I have many seedlings of Amas which have improved on its standards.

Then there is *habit*: even if the individual blooms are not first-rate, a stem which branches freely, so as to show off the flowers on a sort of candelabrum, is highly desirable. I may instance the variety known as Porcelain, the spike of which has great architectural beauty. Not that I would discard such forms as some of the best wild pallidas, because their flowers sit close to an unbranched stem, but I dream of an ideal pallida which should have the flowers of the form called dalmatica set out on the branching candelabrum of Trojana. I have many charming branched pallida seedlings, but I have not yet seen the pallida of my dreams.

Let me mention, in passing, that, as pallida reminds me, a poor form may turn out a good seed-parent. One year, before consigning to the bonfire an extremely poor form of pallida, I gathered its seed. Thence came a race called Proteus, one of which has the largest flowers I have seen in any bearded iris: I have measured one 7ins. from the tip of the standard to the tip of the fall, and the extreme width of the standard was 3ins.

The last essential point is a good constitution; but a weakling generally saves trouble by committing suicide. I had once a Caterina seedling with light blue-purple falls and pure white standards, but I only saw it once. It is probably wise to see a seedling in flower at least twice before deciding on its merit—that is, of course, if it has good points on its first appearance, as these good points may tend to disappear the second year.

NEW AND RARE CHINESE SHRUBS

DEUTZIA LONGIFOLIA.

IN its best forms I should place this deutzia among the first half-dozen for border and pleasure ground planting. Vigorous and free in habit, it is later in growth than the forms of D. gracilis, thus escaping frosts, which damage the young growths of this species.

D. longifolia is an attractive deciduous shrub with arching branches of purplish rose blossoms abundantly produced in June. The individual flowers are ¾in. to 1in. across. The ultimate height of the bushes, according to Mr. Wilson, being 4ft. to 6ft.

The deutzias are readily increased by cuttings made of the half-ripened wood placed in a heated propagating frame from the middle of July onwards. Few shrubs give better results when the ground is liberally trenched and manured.

D. longifolia was originally collected by the Abbé David in Moupin, being described and named by

ONE OF THE FINEST OF CHINESE DEUTZIAS, D. LONGIFOLIA.

Digitized by Google

ONE OF THE MANY NOTEWORTHY HARDY SHRUBS INTRODUCED FROM CHINA. DIPELTA FLORIBUNDA.

Franchet in 1885. No seeds were, apparently, included, as the first plants introduced appear to be those raised from seeds collected in western China by Mr. Wilson in 1903.

The variety Veitchii was the name originally intended for a form with open flowers of a rich purplish rose tint, but seedlings vary so much in colour, as do plants growing in sun or partial shade, that it is difficult to define the difference or draw a definite line between the two.

DIPELTA FLORIBUNDA.

Among the many new hardy shrubs introduced from China during recent years, Dipelta floribunda is one of the most distinct and valuable acquisitions. A deciduous shrub of vigorous habit, Mr. Wilson records it occurring as bushes ranging from 4ft. to 15ft. in height. The dipeltas are allied to the diervillas and thrive under similar cultural conditions. The blossoms are very freely produced towards the end of May and early in June. They are pleasingly fragrant with a funnel-shaped corolla, the exterior rose-pink, white inside with a yellow throat. A feature of the bushes is the bracts at the base of the ovary which form thin disc-like wings developing with the fruits. The dipeltas are easily increased by cuttings, which root readily in a close frame towards the end of July and during August.

D. floribunda was first discovered in Shensi by a Russian surgeon, Dr. Piatsetski, in 1874 or 1875, Maximowicz's description being made from his specimens. The first living plants were sent home by Mr. Wilson in 1902, seeds following in 1904. Mr. Wilson also collected this dipelta again during 1907 and 1910 in western Hupeh, as it is a native of both central and western China. Two other species are in cultivation, D. ventricosa and D. yunnanense.

STYRAX HEMSLEYANUM.

A native of central and western China, specimens of this beautiful styrax were collected by Professor Augustine Henry during the year 1888 in Hupeh. For its first introduction to our gardens we are indebted to Mr. E. H. Wilson when collecting on behalf of Messrs. James Veitch in 1900. The first seeds were collected in western Hupeh, the subsequent plants flowering for the first time during 1909 in the Coombe Wood Nursery and providing material for the *Botanical Magazine*, Tab. 8339, of 1910. Mr. Wilson found the plant again during 1908 in western Szechuan.

S. Hemsleyanum is a large deciduous bush or small tree 20ft. to 30ft. high, with large nut-like leaves. During June the pure white flowers are freely borne in terminal and axillary racemes or panicles. There are from about eight to twenty blossoms in an inflorescence, each about 1in. across and pleasingly fragrant.

In common with all the species of styrax, the subject of this note should be given preferential treatment. Shelter from the north and east is important. The best specimen at Kew is growing in a large bed of Erica mediterranea. This provides protection in the early years of growth and permanent shelter for the lower parts of the tree and shades the ground from the drying sun, which is by no means the least important. Previous to planting, prepare a good station of well drained light loamy compost, adding a little leaf-mould and peat if available.

Cuttings may be rooted, though layering provides the best means of increase. As the young trees grow there should be plenty of home-saved seeds, but so far we have had little success with Kew and Cornish harvested seeds. A. O.

THE PURE WHITE FLOWERS OF STYRAX HEMSLEYANUM FREELY BORNE IN LONG TERMINAL RACEMES.

PLANTS FOR THE HOUSE

ONLY WHEN IT IS TOO LATE TO PUT THINGS RIGHT MANY CULTIVATORS REALISE THAT TIMELY ATTENTION TO WINTER-FLOWERING PLANTS WAS NOT GIVEN, AND THAT, IN CONSEQUENCE, THE HOUSE IS NOT SO GAY AS IT MIGHT HAVE BEEN. THE FOLLOWING ARTICLE GIVES SOME HELPFUL SUGGESTIONS ON HOW TO UTILISE ALL SPACE TO ADVANTAGE WITHIN A SMALL GREENHOUSE.

ALMOST before the summer flowers are in their full beauty, we get through the post numerous bulb catalogues to remind us of winter and dark days, when border and rose garden will delight our eyes no longer until summer comes again. To those who hate to be without flowers at any time, the following description of what a small greenhouse can supply may be of interest. It is not intended to apply to those fortunate people who can enjoy the contents of several greenhouses; but, to be definite, all the plants mentioned come from a lean-to greenhouse 15ft. by 12ft., heated by a small boiler which gives just sufficient heat to keep out the frost when severe. This house has to suffice for winter shelter for all cuttings and bedding plants, and (against all the canons of gardening) it harbours a vine and supplies the house with tomatoes. By the aid of impromptu staging and extra shelves, it is surprising what a number of pots can find a resting place in such a small space.

The requirements of the house are that two fairly large rooms should be kept bright for at least ten months of the year. Naturally, after May, the demand for pot plants is not so great; but when the out-of-door chrysanthemums and Michaelmas daisies are almost the only flowers left for cutting, the strain on the pot plants begins. October brings in the first pots of chrysanthemums. Between fifty and sixty of these are grown in various sized pots, chiefly Japanese varieties and singles, with a few incurved varieties. These are not, as a rule, severely disbudded, but are allowed to carry six to eight blooms, while some of the singles are allowed to grow quite naturally. It is convenient to have a few plants in quite small pots carrying one or two blooms. These fit into odd spaces and small receptacles that will not take a larger pot. Through October and November and well into December the chrysanthemums bring colour into the house without being reinforced by other plants, and they continue to add their quota until well into January.

With December on us the bulbs begin. Roman hyacinths or (these having become expensive luxuries) the Dutch miniature hyacinths (now christened "Cynthella") and paper white narcissi are the first comers.

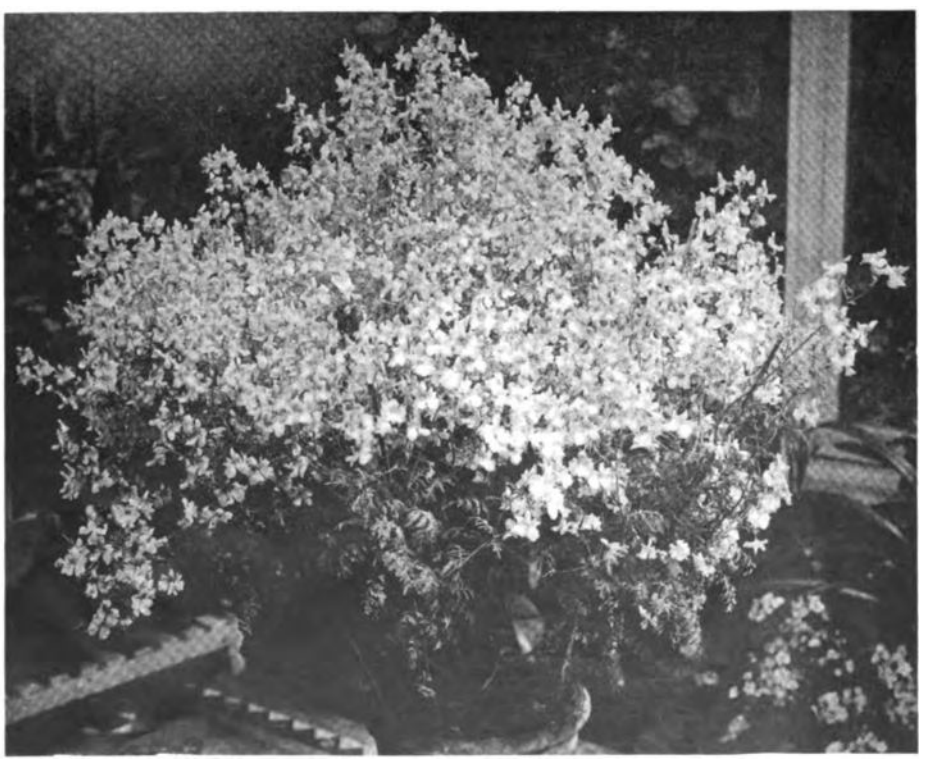
January increases the variety of bulbs. Freesias, with their pleasing scent, are always great favourites in the house, and Golden Spur daffodils—to my mind still unbeaten in colour by any other daffodil—bring us the first promise of spring. Then the polyanthus daffodils, Poeticus ornatus, and the larger hyacinths come in. Of the last, my favourite is the white L'Innocence, but there are so many good varieties that it is difficult to praise one kind more than another. White and blue seem to brighten a room more than the other colours. The pink is not sufficiently brilliant for the dark days. A room is so different from the open garden or the conservatory, for there are so few positions in it that are in full light. This makes it desirable to choose colours that stand out clearly and will brighten dim corners.

During February the hyacinths, daffodils and narcissi carry on. King Alfred is an invaluable daffodil for indoors for form, colour and endurance.

Primulas and cyclamens are brought in to take the place of the freesias, which are losing their first beauty. Then white and pink azaleas, which are coming out at the end of the month, take most kindly to the living-room.

March brings schizanthuses, cinerarias, geraniums and Emperor and Empress daffodils. April ends the indoor bulbs, for their unprotected brethren in the open garden are beginning to assert themselves; but schizanthuses and geraniums continue, and the white hydrangeas—of which there are such beautiful varieties now—fill up the spaces left by the retreating bulbs.

And now colour begins out-of-doors, and the need of the house is not so great. However, through May and June hydrangeas, geraniums and pelargoniums are required, and they go on throughout the summer.



THE PROFUSE-FLOWERING SCHIZANTHUS, WHICH RETAINS ITS BEAUTY AND FRESHNESS FOR A CONSIDERABLE TIME IN A LIVING-ROOM.

I should like to say a word regarding the best "stayers" in the house. The atmosphere and light of a living-room are not very healthy for a plant. I have noticed, too, that plants in a room heated night and day with hot pipes have a shorter period of health and strength than those in a room heated by the ordinary fireplace. Evaporation is much greater, and it may be that, unless care is taken, the roots may get dry. When the staff is small, the watering of the plants in the house

Digitized by Google

passes from the gardener to the lady or daughter of the house. The plants are frequently in ornamental tubs and vases, where the pots cannot be tapped to test whether they are dry or wet; the earth surface is often covered with moss, so that the first intimation of lack of water may be the wilting of the plant; or else "little and often" may be the rule for watering. This means that the surface is always damp and the earth beneath dry—very unfair treatment to give the plant. Where there is a conservatory attached to a room, the plants can be carried out and thoroughly watered at proper intervals; but to take them out-of-doors in frosty or windy weather for watering may do more harm than good.

The flower that preserves its freshness for the longest time in a room is the hydrangea, and, if well grown, it is most effective. You may put it in a hall with no direct light and it will remain cheerful for weeks, though most other plants wilt and grow sickly under the same conditions in a very short time. In an ordinary postion in a room, it will be still a thing of beauty after six weeks or two months of indoor life.

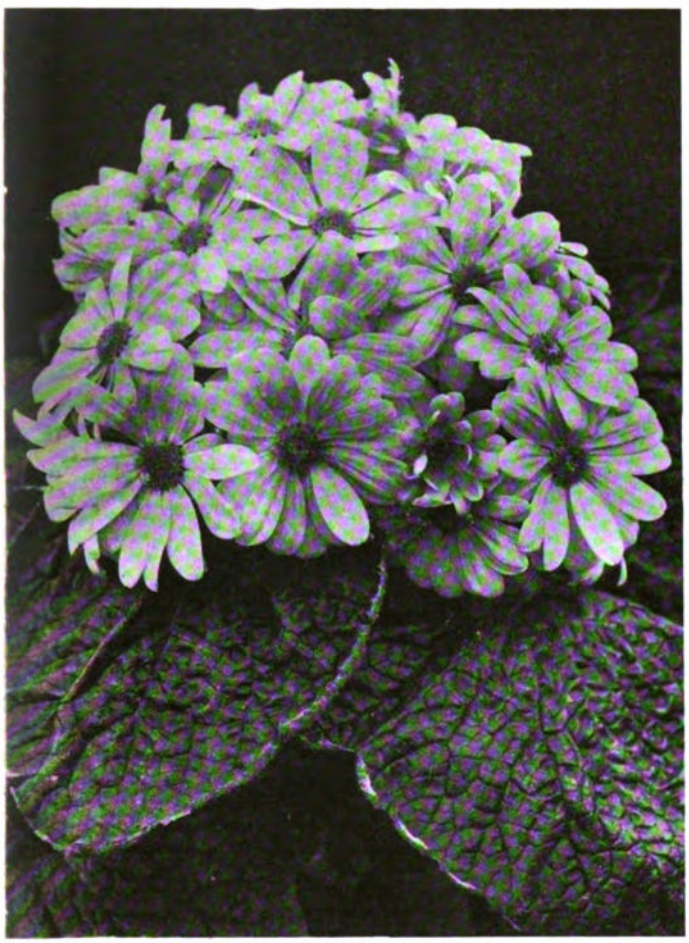
Next to the hydrangea, the ordinary indoor azalea will stand and remain bright for more than a month. After six weeks I have had them removed more from consideration of their constitutions than from lack of beauty. Cyclamens have remained throwing up their flowers from January to April.

Of daffodils, King Alfred is, with me, the longest stayer, though after three weeks it gets rather too long in the stalk. Chrysanthemums are always good in the house, unless fed too generously beforehand. Tulips, crocuses and scillas have been discarded, not because of their lack of beauty, but because, in the house, their period of beauty is a short one, and with such a small space at my disposal this is a serious consideration.

This is not, by any means, intended to be a list of the best plants for adorning a house. A number of these occur to me that it would be very pleasant to possess. Carnations, gloxinias, the sweet-scented cytisus and many others. It is merely intended to show that with limited space and small heating power, the darker and flowerless months of the year may be lightened, and that a small greenhouse can give a continuous supply of two or three dozen plants for the house for at least seven months of the year. The following table will show at a glance what can be reasonably expected under the conditions above described:

October-November	Chrysanthemums.
December	Chrysanthemums, Roman hyacinths, paper white narcissi.
January	Chrysanthemums, freesias, daffodils (Golden Spur).
February	Polyanthuses, Narcissus Poeticus ornatus, hyacinths, daffodils (King Alfred), primulas, cyclamens.
March	Daffodils (Emperor and Empress), schizanthuses, cinerarias.
April	Hydrangeas, geraniums, cinerarias, schizanthuses, azaleas.
May, June, July ..	Hydrangeas, geraniums, pelargoniums.

N. J. N. VICARS-MILES.



A FINE TYPE OF THE FLORIST'S CINERARIA.
These old-fashioned flowers add a decided charm to the house.

HYDRANGEAS ARE VERY EFFECTIVE PLANTS IN THE HOUSE.
Their massive trusses of bloom do not scatter their florets.

GLADIOLI AT VINCENT SQUARE

ONE could not but be surprised on entaring the Royal Horticultural Society's Hall, Vincent Square, on Tuesday, August 12th—the occasion of the fortnightly meeting—to see the fine collections of gladioli, phloxes, zinnias, etc., which were on view, having regard to the fact that it was marked down specially as a show for peaches, nectarines and apricots in addition to the flowers of the season.

One would have imagined it to be principally a show of gladioli backed up by roses, sweet peas and general herbaceous plants, the fruit being markedly conspicuous by its absence. However, it's an ill wind that blows nobody good, and one could at least feel thankful to the exhibitors for maintaining the usual high standard of excellence. The attendance, unfortunately, was below the average, but no doubt the time of year and the nature of the Show as printed accounted for that to a large extent.

A large collection of large-flowered hybrid gladioli was shown by Messrs. Sutton and Sons. The blooms were in excellent condition and exceptionally well staged. Here were to be seen such well known sorts as America, Odin, White City, Red Emperor, White Giant and Marechal Foch.

In another part of the hall the Reading firm had a large collection of double-flowered zinnias. The range of colours in these flowers was really wonderful.

Messrs. R. H. Bath, Limited, had a fine lot of gladioli. The following sorts were conspicuous: Lene Graetz, Thibet, La Savière, Souvenir and White Giant.

Messrs. Kelway showed their famous "Langprim" hybrids. Of outstanding merit were Field Mouse of a wonderful colour; Topaz, salmon pink, suffused buff; Firefly, deep scarlet; Master Weitse, violet blue; and John Churchill Cragie, salmon, with yellow blotch.

Mr. Alfred Edwards showed a batch of primulinus hybrids.

Messrs. Lowe and Gibson showed a unique collection of seedlings which had originated from seed sown in 1923. There were some wonderful shades in some of the flowers shown. This exhibit was an object-lesson. It proved that wonderful results can be obtained by sowing seed one year and obtaining excellent blooms the next.

Major Churcher staged a very good exhibit. The following sorts strongly appealed to us: Diana, deep scarlet; Scarlet Princeps; Nightingale, rosy pink; Salmon Plume.

Messrs. Bunyard and Co. showed a very representative collection of gooseberries. The fruits were in excellent condition. Besides gooseberries they showed apples and gages.

Messrs. Daniels Brothers, Limited, showed their new September Black Currant. There were fruiting sprays on view laden with the large luscious black fruits. This currant appears to keep up its reputation as a heavy cropper and vigorous grower. The fruits are of enormous size.

Mr. H. J. Jones had a large ground exhibit of herbaceous phloxes in the centre of the hall. The plants were shown in baskets. Unfortunately, some of the blooms showed traces of the recent wet weather. Here were such sorts as F. A. Buchner, pure white; Mrs. Jeans, pink, shaded mauve; Dr. Charcot, parma violet; Eugene Danzanvilliers, heliotrope, white centre.

It was a great pleasure to see Messrs. Vert's hollyhocks. There is no firm which has done so much to improve this stately border plant as Messrs. Vert and Sons. The exhibit under review was an "eye opener" to those who were fortunate enough to see it. The magnificent blooms borne on stiff stems were of every conceivable colour. It is not possible to mention all the varieties shown but here are some that especially appealed to us: Lord Kitchener, deep crimson; Lilacina, lilac mauve; Alba superba, white; Queen of Yellows; Lady Bailey, flesh pink; Black Knight, exceptionally dark.

The Donard Nursery Company had an interesting exhibit of Dierama pulcherrima hybrids which showed a wide diversion from the type plant, especially as regards the length of the spikes.

A comprehensive collection of dahlias was staged by Messrs. Joseph Cheal and Sons. To enable visitors to study the many sections of this flower Messrs. Cheal and Sons arranged them in their respective sections. This firm also showed peony-flowered dahlias on boards.

In a miscellaneous collection of plants Messrs. B. Ladhams, Limited, had a very fine bloom of Romneya Coulteri and showy blooms of Lavatera Olbia rosea.

The only exhibit of sweet peas was staged by Messrs. Robert Bolton and Son. Three outstanding sorts were Empire, Wembley and Powerscourt.

A large exhibit of violas was put up by Mr. Wm. Yandell of Maidenhead. Outstanding sorts were Mrs. Chichester, white, edged and flaked mauve; Moseley Perfection, yellow; Klondyke, yellow; J. V. Macdonald, pure white, yellow eye.

Herbaceous plants, including phloxes, were shown by Mr. W. Wells, jun. Here, too, was the quaint Netera depressa.

Giant streptocarpuses were exhibited by Messrs. R. and G. Cuthbert. Two outstanding sorts were Giant Mauve and Southgate White.

There were two or three exhibits of roses. Messrs. W. Easlea and Son had a very well arranged group in which the following sorts were noteworthy: Margaret D. Hamil, Lamia, Golden Ophelia and Mme. Butterfly.

Messrs. Chaplin Brothers showed such good sorts as Innocence, Mrs. Charles Lamplough, Maud and Los Angeles.

Messrs. D. Prior and Son and the Rev. J. H. Pemberton also showed good groups of roses.

Perennial scabious were shown by Messrs. Isaac House and Son.

Greenhouse plants, including many fine cannas, were staged by Messrs. L. R. Russell, Limited.

Hardy plants were shown by Messrs. Amos Perry, Messrs. M. Prichard and Sons, the Misses K. and E. Hopkins.

Perpetual-flowering carnations were staged by Messrs. Allwood Brothers and Mr. C. Engelmann. The former staged such well known sorts as George Allwood, White Pearl and the brilliant Scarlet Edward Allwood, and also showed their famous Dianthus Allwoodii, including many new sorts. In Mr. Engelmann's exhibit we noted the well known Laddie, light salmon pink and Topsy, deep crimson.

A miniature rock garden was shown by Mr. H. H. Claydon of Bishop's Stortford. It certainly was very original, and was complete even to steps and waterfall.

NEW AND RARE PLANTS.

BOMAREA CANTABRIGIENSIS.—A very effective hardy hybrid, with its broad lanceolate leaves, with their well known twisted petioles and their umbels made up of numerous flowers, the corollas of which were, as usual, waxy, wavy and rather dull in colour, of a yellow to pink tinged with spots of brown red. Award of merit. Shown by the Director, Botanic Gardens, Cambridge.

CLETHRA FARGESII.—A native of central China and one of the most ornamental shrub species on account of its very long racemes of white flowers showing up to advantage against the oblong ovate dark green leaves which are pointed at the tip and nearly glabrous. Award of merit. Shown by Colonel Stephenson R. Clarke, Sussex.

DIERAMA PULCHERRIMA "KINGFISHER."—A plant which looks specially well as a background with its long, narrow, sword-shaped leaves, slightly shorter than the type, and its flowers bell-shaped, pinky mauve in colour, borne in a long woody panicled spike, and pendulous. The flowers of this form are much lighter than those of the type, which are blood-red purple. Award of merit. Shown by the Donard Nursery Company.

EUSTOMIA RUSSELLIANUM.—This representative of the gentianaceæ bears most of the characteristics of the order, with its pale to glaucous opposite green leaves and pleasing blue flowers more or less paniculate. The corollas were of a good bell shape. The lobes were more or less oblong, and whitish at the base. The whole plant had a graceful habit. Cultural commendation. Shown by the Director, Botanic Gardens, Cambridge.

GLADIOLUS E. H. LIDDELL.—This is an excellent specimen of the large-flowered section of gladioli for which Messrs. Kelway and Son have already made a name for themselves throughout these isles and beyond. In colour it is a shade of magenta, the lower petal with a whitish base and centre. It appears soft and delicate. If the name implies anything it should go far, as it is called after one of our recent Olympic victors. Award of merit. Shown by Messrs. Kelway and Sons.

HOHERIA POPULNEA VAR. LANCEOLATA.—A representative from New Zealand with a peculiar name, no doubt taken from the vernacular. It is a small but handsome tree, reaching 20–30ft. in its native habitat. The leaves, as the varietal name implies, are lanceolate, though somewhat variable. The flowers are snow-white and are produced in great profusion, the plants being literally covered with blossom. For ornamental purposes it should be especially valuable, although, unfortunately, it may not take to all soils and localities. First-class certificate. Shown by Mr. G. W. E. Loder, Sussex.

HYDRANGEA OPULOIDES, VAR. CŒRULESCENS.—This was a beautiful specimen of one of these highly prized ornamental plants, with its light green opposite leaves and large, dense, roundish cymes of blue flowers. The marginal or neuter flowers, with their expanded white to pink calyx, stood out in strong contrast to the blue of the fertile flowers. It probably is related to H. Hortensia, if not a form of it, where such variation often occurs. Award of merit. Shown by Mr. G. W. E. Loder, Sussex.

HYDRANGEA OPULOIDES ALBO-ROSEA.—Another handsome plant of the same genus. Here the leaves varied somewhat from the type, being much smaller—broad ovate to ovate. The inflorescences were rounded with the flowers in whitish to yellow trusses, the outer flowers round the margin with their conspicuous deep pink bracts making a very charming picture which was worthy of the award. Award of merit. Shown by Mr. G. W. E. Loder, Sussex.

ODONTONIA JOICEYI (Odontonia Pittie × Odontoglossum Tityus).—This young seedling bore a single flower, the sepals and petals effectively marked with rose-purple, the expansive labellum rose-flushed and with purplish marking, the yellowish crest lined with bright red. Award of merit. Shown by Messrs. Charlesworth and Co.

PATHS IN GARDEN DESIGN

PATHS play a very important part in the design of a garden, and serious mistakes often occur if they are not given the attention due to them in the initial planning. Much care should, therefore, be taken to consider very carefully the value of their proportions in relation to the rest of the garden and to each other.

The chief objects to bear in mind when first deciding the positions of garden paths are beauty, comfort and the efficient working of the garden. They should be placed where they are most needed to serve the various parts of the garden, such as the kitchen and flower gardens and tennis court. Where possible they should follow the line of least resistance and by so doing give a sense of "decided direction" and purpose—a quality which affords great rest—as opposed to the restlessness created by the purposeless paths of the naturalistic school of gardening. This line of least resistance will usually mean a straight course from point to point when the ground is moderately level. If variety is needed it should be provided by supplying an obvious reason for the detour, such as a clump of trees, a sundial or some other definite object: otherwise the design will at once become aimless and indefinite.

Broad straight paths give a sense of spaciousness even in a small garden, whereas the effect of perspective on a long narrow path is to render it insignificant and to convey a feeling of scampiness to the general effect.

The comfort of a dry walk around a house cannot be over-estimated, but it is well to shrink from the use of ugly barren gravel, as it is most uninviting to walk upon and is very rarely in harmony with the architectural material of the house. It is better to look with favour on the careful use of paved walks, which have all the advantages of gravel with none of its ugliness, and they also make a splendid setting for both flowers and grass. It is usually on grounds of expense that gravel is used. Where possible, the same material should be used as that with which the house is built, whether it be tile, brick or Yorkshire stone. Old London stone, owing to its delightfully neutral colour, will be found most pleasing in combination with almost any other stone. Paving flags are often shamefully misused, but if they are treated in a purely formal way most interesting and varied designs can be made. The extensive use of crazy paving near the building is incompatible with the formality it is so important to preserve round the precincts of the house. Out of sight of the house crazy paving can be used with great effect in the making of dry walks.

The combination of a dry walk with the freshness and beauty of close-cut grass can be obtained by sinking flagstones just below the level of the turf at convenient distances when walking at a slow pace. Where the path diverges, a specially selected large stone should be used at the juncture. Each stone should be firmly blocked underneath to prevent sinkage, more especially when the soil is of light nature, and great care should be taken in placing the stones, both to produce a pleasing effect when all is finished and also in such a way as to allow the mowing machine to pass quite freely above, without damaging the blades.

Difficulty is so often experienced in trimming the edges of grass paths, and even with the mowing itself, when the low-growing plants on the border's edge bulge forward on to the path in their healthy and natural growth. A simple and very attractive way to combat this is to place a single line of flagstones on the edge of the grass path, keeping the straight face of the stone towards the centre of the path. The plants can then grow freely over the stone and show their beauty of form with no fear of being ruthlessly chopped away, a pitiable sight too often seen.

Grass paths, if kept well, make one of the best settings for flowers, but they have many grave disadvantages. They will not stand much wear and tear and at the same time keep their beauty; it is, therefore, as well to avoid using them in the kitchen garden or where there is much continual traffic. In any case, reserve them for that part of the garden most used in the summer months, where a cool green path is a comfort and a hard dry path is not essential. They must be kept perfectly soft and springy, fresh and of a deep green colour, with the straightness of their edges above criticism, otherwise their restfulness and sense of order and cleanliness will be immediately lost.

GRASS WALKS, IF WELL KEPT, MAKE ONE OF THE BEST SETTINGS FOR FLOWERS.

Formality, which should be the motive of the garden design round the house, is out of place in the wild garden, where the paths should be made to look as natural as possible, like woodland tracks, both in the direction and method of their making. Where the growth is open enough the path should first be cut with a machine, and then the hard edge on either side cut away slantingly with a bagging hook; this will soften any hard effect caused by the track of the machine.

Well kept paths do much to make even a poorly designed garden attractive, but where the design is good they are the keynote of its success, and greatly assist in lending enchantment to the surroundings. It is well, then, to aim at formality in the design, and simplicity combined with usefulness in their construction.

LILIUM CANDIDUM.

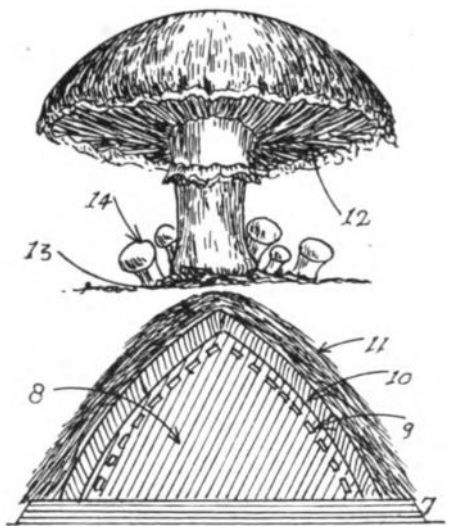
IN many cottage gardens these lilies thrive and flower freely, often retaining their leaves till the last flower has faded. In hundreds of other gardens the plants are partly, if not quite, a total failure. The question is often asked why is this the case, and why cannot more cultivators grow this lovely lily really well? In the first place the bulbs do not like being disturbed when once they are well established in a border; in the second, re-planting should be done quickly, before the bulbs get dry; in the third, only sound bulbs should be planted. Of course, many lovers of these lilies are obliged to take up and re-plant the bulbs. Where this work must be done for various reasons, preparations for carrying it out satisfactorily should be made before the end of August so that all of it may be completed before the end of September. Good open loam is the best; if poor, it should be well enriched with rotted manure. Even the best soil should have rotted manure mixed with it freely. Good drainage is essential; sites should be chosen with this end in view. The bulbs increase in number so we need not plant more than three in one position. Having made the hole and added the manure to the soil, place the bulbs 9ins. apart and bury them with soil, free from manure, several inches deep. If these precautions are taken there will not be much risk from canker and fungus.

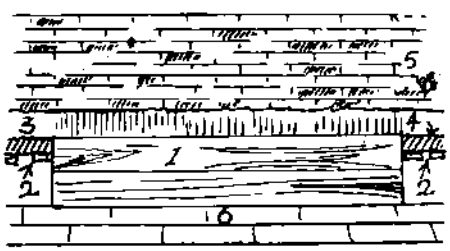
WINTER LETTUCE AND ENDIVE.

There are many very successful cultivators of these plants throughout the autumn and winter time, and some of them may think that others cannot fail to grow them well, too. But, alas! there are many dismal failures; certainly soil and situation count. In a low-lying district and where a clayey soil obtains, there is a disadvantage to begin with and special means should be taken to encourage early, healthy growth. The plants should be raised a fortnight earlier than in gardens where the soil is light and the situation naturally dry. For the winter supply the young plants should be well forward now; for the spring supply seeds may be sown forthwith. In every instance transplant the young seedlings twice, first time when quite tiny in a nursery bed 3ins. apart, second time in their permanent quarters 9ins. apart each way. Endive, 1ft. apart and 16ins. asunder in the rows. Of course, rough frames are ideal for lettuce and endive in the winter, but such cannot always be spared for the purpose. In very clayey soils in the open I like to form tiny ridges about 3ins. high and 7ins. wide and to plant the lettuce on the west, or south side, not exactly on the ridge, the plants thus receive some protection from wind and moisture. Slugs are very troublesome and to combat them strew the surface of the soil with dust lime prior to planting and with finely sifted ashes after. Early endive is readily blanched by laying old pea sticks on the plants and mats on the sticks.

HOW TO GROW MUSHROOMS

Mushrooms may be grown in sheds, cellars, under stages in greenhouses or in the open air and the present is a suitable time to make up such beds. Only the essential points can be given in this short note, but the sketches will help considerably. Fresh horse-droppings and a





small proportion of short litter, should be collected daily, placed in a thin layer in an open shed and turned daily to expel the rank gases. The beds should be very firmly made, inside ones 15ins. deep, outside ridge-shaped, 3ft. at the base, 2ft. 6ins. high to the ridge. The spawning should take place when the temperature is declining and registers 85°. No. 1, front boards supporting bed against a wall. Nos. 2, 2, lumps of spawn. No. 3, surface of bed. No. 4, soil covering 2ins. deep. No. 5, wall. Straw is placed on the bed. No. 6, floor. No. 7, raised ground for outside bed. No. 8, the bed. No. 9, spawn. No. 10, soil. No. 11, straw covering. No. 12, stage at which the mushroom should be pulled up. No. 13, No. 14, young mushrooms.

ANNUALS FOR THE GREENHOUSE.

All who have seen well grown annuals in a greenhouse in spring will be anxious to have some in their own structure. The plants are not difficult to grow, but the raiser should give them close attention from the seedling to the flowering stage. He should avoid overcrowding at each re-potting, even if this means that only a few plants of each kind can be accommodated. I do not refer to hardy annuals solely, but to tender and half-hardy ones and also to a few biennials, such as stocks of the Brompton type. The best way to grow these annuals is to wash and dry some 3½in. pots, to place one crock in each, nearly fill with a good compost of loam, leaf-soil and sand or old mortar rubble and to water prior to dropping a few seeds in the centre of each pot, lightly covering with sifted soil, but not watering afterwards till necessary. The resultant seedlings should be thinned to one specimen in each pot and the plants given frame treatment till Christmas. Earlier-raised seedlings should be thinned without delay now. The necessary repotting should be done in October.

MIGNONETTE IN POTS.

These charming little plants, with their spikes of fragrant flowers, are greatly appreciated in the early springtime. Except in favoured localities where odd plants will flower modestly outside, having survived the winter, the only satisfactory way to obtain a batch of plants in flower early in the year is to grow them in pots. Seeds should be sown now. If plants are raised too early they flower too soon and so spoil their chance of blooming profusely just when wanted. First, procure some 3½in. flower-pots, wash them well and dry thoroughly before putting in the single crock and compost. This cleanliness is necessary to enable the workman to turn out the ball of soil neatly, without roots clinging to the sides of the pots, when re-potting is done. Good fibrous loam, two-thirds; leaf-soil, one-third, with the addition of a small quantity of old mortar rubble, will form a suitable compost for the plants. Three-parts fill the pots, sow several seeds of mignonette in each one and lightly cover with fine soil; water, and place the pots in a cold frame or on a bed of ashes outside. Shade till the young seedlings appear. When the latter possess two rough leaves, thin to one plant in each pot. Grow on shelves in the greenhouse; re-pot in January into 6in. pots, and take off the tip of each plant if many spikes are required. GEORGE GARNER.

NOTES FROM CONTRIBUTORS

SOME NEW ZEALAND PLANTS.

DWELLERS in maritime districts are giving more attention than of yore to the rich flora of New Zealand. It was long before many of us realised that it was not in Devon and Cornwall alone that plants tender or half hardy in midland Britain would flourish along the whole western seaboard as far north as Cape Wrath, and on many parts of the East Coast also, wherever shelter from violent winds can be given them. We are learning something about the capabilities of our climate at last, and are taking advantage of the experience of a few amateur pioneers. Some of the shrubs of New Zealand are at their best in late summer and autumn after the flush of spring and early summer is past.

The numerous species of olearia, for instance, provide a long and lavish succession of bloom, beginning with OO. nitida and stellulata in May, followed by OO. semidentata, macrodonta and ilicifolia in June,

VERONICA SALICIFOLIA, ONE OF THE MOST HANDSOME OF THE GENUS.

and finishing with OO. avicenniæfolia and Haastii in August. O. Traversii may be mentioned only for avoidance, for its dingy flowers, though borne in great profusion, are quite devoid of beauty.

The lace-bark—Gaya (Plagianthus) Lyalli—is perfectly hardy near the sea, attaining the stature of a moderate-sized tree. Mr. Bean records that it was killed to the ground at Kew in the winter of 1908–9, but grew afresh from the base. Even so, it is well worth persevering with it in inland districts for the sake of the profusion of large, milk-white blossoms with which it wreathes its branches in late summer. There are two forms of this tree, one with greyish, downy foliage, the other and finer variety with almost glabrous grass-green leaves, borne on 2in. petioles with a blade 5ins. to 6ins. long and 3ins. to 4ins. wide. (Such are the dimensions in our plants, though Cheeseman in his "Flora of New Zealand" makes the leaf-blades only 2ins. to 4ins. long.) It is worth while to hold one of these leaves against the light and observe the beautiful venation through a lens. The foliage of gaya looks so soft as to suggest giving the plant a very sheltered place; but, in fact, it stands with impunity very severe buffeting from wind, the long, flexible foot-stalks serving to protect the leaves.

The bottle-brush plant—Callistemon speciosus—here got cut to the ground last winter in the open border, but it is perfectly safe when trained against a wall, where it makes a brilliant display from midsummer onward. Clianthus puniceus is more sensitive to cold; we had a large plant killed outright last winter, owing to its inveterate habit of starting growth about Christmas; but it is well worth persevering with this splendid shrub, which must have the protection of a wall. If that wall be part of a low building the clianthus will spread its scarlet and green drapery over the whole roof.

The genus Senecio is of ignoble repute in this country owing to our native irrepressibles—groundsel and ragwort; but there are many fine members of the family in New Zealand. Senecio Greyii and S. laxifolius (I confess to uncertainty as to which is which) cover themselves with golden flowers in many parts of Great Britain; but S. Huntii, which rises to a height of 20ft. in the Chatham Islands, is seldom seen. It is more tender than S. Greyii, but thrives vigorously on our West Coast, and provides a brilliant display in August. The white-rayed S. Hectori generally survives the winter, but gets too badly cut to give us any bloom, though it does well in some Irish gardens. S. elæagnifolius var. Buchanani is hardy enough to flourish in the Edinburgh Botanic Garden, but its merit as a garden plant consists only in the broad, leathery, shining leaves, densely clad with buff tomentum on their undersides, the rayless flowers having no decorative quality.

The genus Veronica outnumbers all others in species native to New Zealand, and many of them present so many varieties as to puzzle the most erudite botanist. Even the late Mr. Cheeseman, the most comprehensive authority on the flora of those islands, owned that he was baffled in attempting to classify the species, owing to the multitude of intermediate forms and natural hybrids. Certainly I cannot pretend to distinguish between such nearly allied species as VV. salicifolia, parviflora, angustifolia, etc.; but the handsomest of the family known to me is the form of V. salicifolia shown in the illustration herewith. It never fails in profusion of flower season after season, the crowd of long white racemes giving the impression of a rippling fountain. Propagation is most easily effected either by cuttings or seeds, and, to prolong the period of bloom, plants should be placed under varying conditions of light and exposure.

No collection of New Zealand plants can be considered truly representative without a group or isolated specimens of Cordyline australis (formerly known as dracæna), which, however, is only hardy in our milder maritime districts. The huge mass of flowers furnishes a sure attraction for bees, but unluckily is carried at such a height above the ground—15ft. to 30ft.—that one cannot often get a whiff of its peculiar fragrance.

At the risk of taking up too much of your valuable space, I cannot refrain from mentioning that most desirable evergreen for maritime exposure, to wit, Griselinia littoralis. The male and female flowers are inconspicuous and are borne on separate plants: the merit of this small tree consisting in its broad shining green leaves. It forms an admirable wind-break, but is not hardy except near the sea.

It may be worth noting that, whereas the same species of plant may be found in both the North and South Islands of New Zealand, it is desirable to obtain plants from the South Island for introducing to British gardens, the climate of that island resembling our own more nearly than that of the North Island.—HERBERT MAXWELL, *Monreith*.

LILIUM PHILIPPINENSE FORMOSANUM PRICE'S VARIETY.

IT is to be hoped that the somewhat formidable title of this delightful plant will not deter gardeners from acquiring it. Among the hundreds of fine plants which have been introduced to cultivation in recent years, this alpine lily stands out as among the very choicest. The typical Lilium philippinense has been grown in greenhouses for many years, but coming from such a warm climate is, of course, too delicate for outdoor culture. The present variety was found in Formosa at a considerable elevation by Mr. Price (who collected it); consequently it is far better suited to the British climate. An established bulb sends up a sturdy flower stem 18ins. high, on which one to four long trumpet-shaped blooms are gracefully poised. The long narrow tube is characteristic of this lily and measures 6ins. from the base to tip of the petal. The flower is pure white, of great substance, emerald green in the throat; the outside of the petals is stained with purplish crimson, sometimes giving a delicate pink flush to the recurved petal tips.

The readiness with which this lily comes from seed is one of its great attractions, and should lead to its becoming as popular as L. regale. I sowed ten seeds in a pot in a cold frame in March, 1922, and now rejoice in the possession of seven strong-flowering bulbs. Two of these actually flowered last summer, eighteen months after seed-sowing, while at present they are carrying respectively four, three, three, three, two, one and one flowers apiece. They were planted out in the late autumn of 1922 in peaty loam on a bank sloping gently to the north, well sheltered by dwarf Japanese azaleas. A plant of Gentiana lagodechiana has now spread itself over the bulbs and makes a beautiful carpet for the lilies with its rich blue flowers, and doubtless helps to keep the soil cool in dry weather. I understand that this lily

Digitized by Google

is not a success at Kew, but that it thrives in the Edinburgh Botanic Garden. It is certainly well worth a trial in any garden where choice plants are appreciated, and those who succeed with it will feel truly grateful to Mr. Price for its introduction.—N. G. HADDEN. *West Porlock, Somerset.*

ROSA WICHURAIANA.

IF this rose has been eclipsed from an ornamental point of view by the many fine hybrids raised from it, there are several reasons why it will always be cherished by some of us. In the first place, the fact that it is a species will always accord it a place of distinction. Then, it is one if not the last of all the wild roses to flower, its snow white trusses seldom being much in evidence until August. Its habit is also distinct, for it is a quite prostrate grower, its long, slender branches, which may travel a dozen feet in a season, creeping along the surface of the soil, a feature which has been inherited to some extent by not a few roses of the class that bears its name.

R. Wichuraiana is, moreover, a most adaptable plant. Though a sun-lover, it is not averse to considerable shade, and it will prosper exceedingly in any poor, light soil. Indeed, we have used it for covering sun-beaten, rocky banks where few things of the kind would grow; but it is, I think, most attractive when planted among some of the dwarf heaths. Through these latter it threads its long branches, and it has never yet shown any tendency to become too dense and heavy for its companions, nor is it ever pruned or attended to in any way. In addition to the white-flowered type, there is var. rubra, with the same procumbent habit and larger flowers of a rich crimson with a white base. This rose, which some consider a hybrid between the above and Crimson Rambler, does not appear to be so vigorous as the type, but it begins to flower rather earlier, and both will continue in blossom until late autumn. If one has any choice in the matter, the hybrid should be given the better place, since it is not only less robust than the species but a little inclined to mildew. —A. T. J.

MEDICINAL VALUE OF THE ONION.

NO plant in the kitchen garden gives such a delicate and delicious flavour to meat dishes as the onion, and someone has said that of a hundred recipes destined to allay the hunger of our long-suffering army, ninety-nine contained onions as an ingredient. Why there should be a foolish prejudice against the vegetable because of its somewhat pungent odour is rather hard to account for, but if properly cooked, it has an imperceptible effect on the breath. It is the raw onion that gives the breath the objectionable odour, though a little parsley eaten will quickly remove this. But the raw onion is not without its good properties, and those who relish such will find in it a tonic of much virtue. An onion eaten raw or stewed is a homely remedy for a cold, while as a nervine there is no better vegetable. The onion is also credited with being one of the best blood purifiers in the vegetable kingdom. The Greeks held it in the highest esteem, both as a medicine and a food, and invariably dosed their criminals with a mixture of onions and sulphur as a purifactory process.

Among the Romans, Nero was an absolute devotee to onion worship, and sundry days in each month were solemnly set apart on which he feasted exclusively on this unimperial diet, being impelled thereto by considerations of vanity rather than health, as he had a firm conviction that onions improved the voice. Onions are certainly excellent for the complexion, and their juice was an invariable ingredient in old cosmetics, its value being, of course, dependent on the sulphur it contains. Country children probably owe much of the clearness of their skins to the liberal use of onions in their diet.

Many of the old herbalists used to recommend onions as an infallible cure for baldness! They were also applied to wounds to stop the bleeding, and to burns to allay the inflammation, but no herbalist, after dilating upon their many "virtues," failed solemnly to warn his readers that being a herb of Mars, no one with a horoscope in which Mars is unfavourably aspected should venture on their use in any form.

Pliny ascribes to the onion twenty-seven remedies. The Greek physicians used onions in wine in catamenia. The Chinese seem to have learned the value of the onion, for next to rice probably no other vegetable is more largely used. In France pneumonia is now being treated by medical practitioners by the use of onion poultices, and it may be used with success in bronchial conditions.

Were the virtues of the onion better known the vegetable would undoubtedly occupy a larger space in the kitchen garden and allotment than is now allocated to its cultivation, with the result that a larger, sounder crop of onions would be secured for use in the dietary to the benefit of the community. Unlike other vegetables, however, it must be remembered that the onion has an extremely sensitive organism, so much so that it attracts to itself any morbid matter in its immediate and surrounding vicinity. Consequently it is unwise to eat onions that have been stored in a badly ventilated room, or in any place where sickness is prevalent.—R. D.

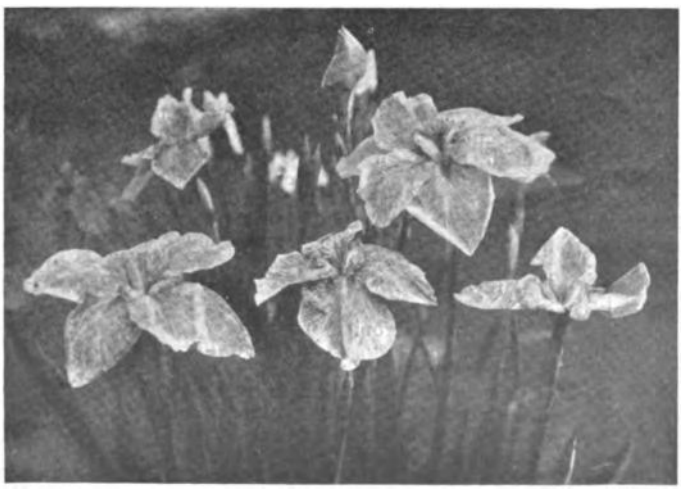
CORRESPONDENCE

SAXIFRAGA CÆSIA.

SIR,—In the illustration on page 537, the saxifraga beside S. cæsia, referred to by Dr. H. Stewart Wacher, seems, as far as I can see with a magnifying glass, to be S. cochlearis minor, which I called S. Probyni (*Gardeners' Chronicle*, 1910, and "Flore des Alpes Maritimes of Burnat, Vol. V, page 83). Of course, it is not cæsia; perhaps it is S. valdensis, which seems often to be called cæsia major but is quite another thing. Grenier and Gordon, in "Flore de France" (Vol. I, page 658), say: "S. valdensis is very near to cæsia, from which it differs by its much bigger size; its leaves are like those of cæsia, triquetres but straighter and only slightly recurved near to the end, where they are almost spathulate. The flowering stems are covered with glandulous hairs and the flowers form a corymb of 6-10 flowers." The stems and calyces are dark and hairy-glandulous, these being its most easily recognised characteristics. It is a rare plant, growing in the high summits of the Queyras at the foot of the Monte-Viso; I found it in the high Maurienne at Bessans, and it has been brought from Mont Cenis by Dr. Jenkin, I think. Your correspondent may identify his plants by the pubescence or smoothness of the stems.—H. CORREVON, *Geneva.*

IRIS KÆMPFERI.

SIR,—I enclose a photograph of Iris Kæmpferi which I trust may prove of interest to your readers. The bloom measured 8ins. across. I hoped to have sent you a good photograph of Campanula Zoysii, but slugs decreed otherwise. I find your paper the greatest help and interest.—L. S. DRURY.



THE FINE BLOOMS OF IRIS KÆMPFERI.

MAGENTA.

SIR,—I was much interested in Dr. Hampton's article on magenta flowers in THE GARDEN, August 2nd, page v, as I discovered by accident how effective they can be, rightly used. A plant of honesty sowed itself under a wall on which hung drifts of purple aubrietia (both were of very deep colouring), and the sight of these two together was a joy for many days. Then by accident some of the old magenta gladioli (Colvilei, I think, got into a grey border among some catmint) and the result was so effective that I am now collecting plants of those hues for the same border, which faces south in front of the house. Some seedlings of a giant thrift, which are a "barbaric" crimson, also look lovely with catmint and mauve Spanish irises; while the crimson lychnis (I think it is called) and a velvety grey plant with crimson flowers, in bloom now, the name of which I do not know, carry on the colour scheme. I wonder if any of your readers could suggest other plants to supplement these (I have a good many grey things—Cineraria maritima, santolina, stachys, Artemisia frigida, raoulia, Tenacetum argenteum and, of course, the lovely catmint; and on the wall behind are Ceanothus Gloire de Versailles, C. rigidus and Brilliant, with Rose Zépherine Drouhin and R. Lady Waterlow. I fill up gaps and keep the colour scheme going by relays of Antirrhinum Nelrose and a bright crimson snapdragon; and there is a little pink erigeron which flowers continuously through the early summer. I should be so grateful if anyone could tell me of other effective combinations in these colours. I got the idea of the grey border from Miss Jekyll's delightful book, and I pore over catalogues (one especially fascinating, from Six Hills Nursery), and dream of colour schemes before going to sleep at night! There is nothing in the world which satisfies one like a garden; although one is never

Digitized by Google

satisfied—and I look forward every week to the appearance of your paper, which is certainly more helpful now than ever.—M. H. W.

PINUS INSIGNIS.

SIR,—In a fairly recent issue of THE GARDEN (April 19th, 1924) I saw an illustration of a Pinus insignis at Dropmore. Without any desire to compete with the beautiful trees at Dropmore, it may interest you to see a photograph of a tree of the same species at Knowle, which enjoys, at any rate, a great local reputation as a fine specimen. Age, eighty-four to eighty-five years; height, 78ft. to 80ft.; spread (between perpendiculars), 84ft.; circumference 6ft. above ground, 17ft. The tree is curious on account of its huge lower limbs stretching out almost touching the ground and then rising to a point: in fact, these lower limbs make it impossible to take measurements of the trunk at ground level.—A. S. DUNLOP.

A HANDSOME SPECIMEN OF PINUS INSIGNIS.

VACCINIUM GLAUCO-ALBUM.

SIR,—To gardeners and any readers of THE GARDEN who are fond of ericaceous plants this cranberry should make a strong appeal. True it may not be hardy everywhere, but it has withstood up to 16° of frost here for several successive nights without protection, and its native home in the Himalayas is at an altitude of about 10,000ft. Growing here in ordinary cool woodland loam and leaf-mould, it is a shrub of about 2ft. in height and promises to grow taller. The foliage is evergreen and the pointed, oval leaves of leathery texture are a pale emerald green above with undersides of a vivid bluish white. This colour also pervades the conspicuous bracts of the flower racemes which latter, appearing in late June, produce pendent cylindrical blossoms very constricted at the mouth and of a delicate blush pink to almost white. In some districts this cranberry is said to fruit freely, the round berries being black with a silvery white bloom.—N. WALES.

ORNITHOGALUM THYRSOIDES.

SIR.—Nicholson says the flowers of Ornithogalum thyrsoides are of a yellow colour, but that there is a white variety with a dark centre. I got some bulbs labelled as above from Holland last autumn, and I might have supposed I had got the white, only the shape of the flower-spike does not coincide with the picture (Fig. 778) which is given in Nicholson's dictionary. It is much more like the inflorescence of arabicum in shape. The individual flowers, too, feature to some extent those of that variety, but they are more open and have pale brown markings at the bases of the petals. In a cold-house it has flowered here in the last week of May, growing from 11ins. to 15ins. high and bearing, in corymb fashion, a number of sweet-scented flowers, which remind me very much of hawthorn. It is a splendid laster when cut and put into vases, for the individual blooms open in succession as if they were on the plant. Would someone who is familiar with thyrsoides tell us more about it? Is it, for example, a less shy bloomer than arabicum? In Bailey's American Cyclopedia, thyrsoides is referred to Plate 1164 of the *Botanical Magazine*, which is a picture of lacteum and very different from what I have as thyrsoides, although Bailey's description, "white with a brown eye," tallies with mine. —JOSEPH JACOB, *Salop*.

CROCUS HYEMALIS.

SIR,—This winter-flowering crocus, which has white flowers, is a source of some temptation to many lovers of hardy flowers who wish to have something in bloom all the year round. Unfortunately, it blooms too late for our climate, and unless we can grow it in pots under glass or shelter it with a hand-light or bell-glass, we are usually doomed to disappointment. I have tried it in the open in a sheltered rock garden without protection, and always the flowers were scarcely ever open owing to the absence of sun in our winter days, or were so sodden by rain that they were reduced to pulp if they escaped the hardships of the frost or the smothering with snow which so often descends on our gardens at that time. It is well, I think, to give this word of warning. It is otherwise if an alpine house is available with slight heat in winter, when a pot or a pan full of this charming white-flowered crocus is lovely when it opens under its sheltering roof. Corms are not too expensive and should be planted as soon as they can be supplied by the dealer.—S. ARNOTT.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Rose Leaves Curled Up (F. W. B.).—The leaves sent for inspection are slightly mildewed. The youngest leaves, so affected, curl more than the matured ones. The extreme ends of the young shoots should be cut off. Growth has been checked by the recent cold weather. The specimen leaves sent indicate a lack of vigour in the plant. Apply several moderately strong doses of manure water. It will not be necessary for our correspondent to do more to them this summer.

Roses and Humea elegans (C. M.).—The leaves are attacked by a beetle called Anisopia horticola. It does most harm, however, to the buds. The maggots exist under the soil and do much harm to the roots of the rose bushes. Apply a good soaking of moderately strong soot water to the roots of each tree—half a gallon to each one twice in one week. The scent of the flowers of Humea elegans will not do any harm to persons near; it is the very fine spear-like hairs that pierce the skin and cause the intense irritation. The fine hairs on the leaves and stems of Primula obconica sometimes have the same effect on some people. The watery blisters follow in mild or severe form.

Some Choice Perennials (C. M. W.).—Anemone japonica, tritomas in variety, helianthus, rudbeckia, solidago (the dwarf variety), doronicum, centaurea, gaillardias, geums, anthemis, coreopsis, montbretias, Alyssum saxatile, auriculas, violas, polyanthuses and primroses. There are several varieties of most of the above possessing the shades required (yellow to deep orange). The flowering season would be from early spring to the end of the summer. The height of the plants will vary according to the richness of the soil.

Failure of Lilliums (A. H. F.).—All the liliums grown by our correspondent (LL. testaceum, candidum, tigrinum and chalcedonium) are loam-lovers, and failure is probably due to the fact that they have been planted in leaf-soil and sand; all the wet from the surrounding heavy soil will almost certainly drain into the prepared holes of lighter material. The holes should be drained with a good layer of clinkers and filled with a compost of good medium loam, with the addition of a little well decayed leaf-soil, and sand or some gritty material to keep the whole open and porous. Two of them at least are lime-lovers—viz., LL. candidum and chalcedonium; L. testaceum is supposed to be a hybrid between these two species, and succeeds under the same treatment. Old mortar rubble is excellent for supplying the necessary lime, as it may be used instead of sand to mix with the compost. A dressing of basic slag, 4 oz. per square yard, applied during the autumn, is excellent for the lime-loving lilies. The fresh compost should be trod fairly firm; when planting, plenty of coarse clean sand should be placed round the bulbs. Lilium candidum should not be planted too deep: if they are covered with about 2ins. of soil it is quite enough, and they should be replanted some time during August. The other three may be planted deeper, from 4ins. to 6ins. Our correspondent's lilies, from his description, are attacked by Botrytis cinerea, a fungus which attacks many lilies, especially L. candidum; before replanting, the bulbs should be dried for a few days and be well dressed with flowers of sulphur. When growing, they should be sprayed with liver of sulphur, using 1 oz. to 3 gallons of water; this should prevent the attacks from fungus.

Lilliums (E. M. C.).—Most lilies thrive best in partially sheltered positions. The best species for an exposed garden are LL. candidum, testaceum, chalcedonicum, umbellatum, croceum, Hansoni, Martagon, pyrenaicum and tigrinum.

THE ROCK GARDEN.

100 Selected Rock Plants (J. M.).—Acæna microphylla; Acantholimon glumaceum, A. venustum; Achillea conjuncta, A. tomentosa; Æthionema pulchellum; Alchemilla alpina; Alyssum saxatile, A. s. citrinum; Androsace lanuginosa, A. sarmentosa, A. villosa; Anemone alpina, A. sulphurea, A. narcissiflora, A. patens, A. sylvestris; Anthemis Biebersteiniana; Aquilegia cœrulea; Arabis albida; Arenaria balearica; Armeria cæspitosa; Arnica montana; Artemisia lanata; Aster alpinus, A. Farreri; Astilbe simplicifolia; Aubrietias

in variety; Campanula carpatica, C. Portenschlagiana, C. pulla, C. pusilla, C. Waldsteiniana, C. excisa, C. Raineri; Cerastium Biebersteinii; Chrysanthemum sibiricum; Cyananthus lobatus; Daphne petræa; Dianthus alpinus, D. neglectus, D. callizonus, D. cæsius, D. sylvestris; Douglasiana Vitaliana; Draba aizoides, D. imbricata; Dryas octopetala; Epimedium rubrum; Erinus alpinus; Eriogonum umbellatum; Erodium chrysanthum; Gentiana acaulis, G. asclepiadea, G. septemfida, G. verna; Geranium argenteum; Geum reptans; Gypsophila repens; Haberlea rhodopensis; Hieracium villosum; Hypericum polyphyllum, H. reptans; Iberis semperflorens; Leontopodium alpinum; Linum salsoloides; Lithospermum prostratum; Macrotomia echioides; Myosotis rupicola; Omphalodes Luciliæ; Onosma echioides; Oxalis enneaphylla; Phlox subulata and varieties; Phyteuma comosum; Potentilla nitida; Primula Auricula, P. marginata, P. rosea, P. viscosa; Ramondia pyrenaica; Saxifraga Burseriana, S. lantoscana, S. cochlearis, S. Cotyledon, S. hypnoides, S. apiculata, S. oppositifolia, S. Wallacei; Sedum spathulifolium; Sempervivum arachnoideum; Silene acaulis; Soldanella alpina; Veronica prostrata; Viola calcarata; Wahlenbergia Pumilio, W. serpyllifolia; Papaver alpinum; Waldsteinia fragarioides; Trollius pumilus.

THE ROSE GARDEN.

Rose Moyesii Not Setting its Hips (Mrs. J. P. B.).—As the plant is such a fine specimen, the hips, in the ordinary way, should form freely. The seeds in the berries sent for examination are sterile. Next November, or about the middle of December, remove the surface soil deep enough to bare the roots, and replace it with fibrous loam and rotted manure, mixed. In the meantime, make a garden fire strong enough to burn the soil as well as wood and coal ashes. Procure a barrow-load or so of this burnt mixture and apply it as a surface dressing next February. When the flowers are opening, and throughout the flowering time apply clear water freely and the berries should swell normally.

THE FRUIT GARDEN.

Apple-tree Leaves Turning Brown (A. C. B.).—The cause may be found at the roots of the tree if the branches are not cankered. It comes from some weakness of the tree and deficiency in the flow of sap to the leaves. The remedy is to surface-dress the trees with loam and rotted manure and to apply several doses, at fortnightly intervals, of weak manure water. The young shoots will be induced to continue a more healthy growth of shoots and leaves; the roots, also, becoming more active.

Fig Trees not Fruiting (J. H. H.).—Undoubtedly the soil is too rich for the fig trees. When the young fruits are just formed the ends of the shoots should be pinched off; this will cause the fruits to swell. Hard pruning must not be done, but young, very strong shoots should be rubbed off when quite small. To each square yard of surface soil, covering the main roots, apply a spadeful of old mortar rubbie or 6oz. of lime in the autumn every year, and fork in the material. It is usual to hard-prune the tamarisk in February; flowering follows in some cases and not in others. Unpruned plants grow lanky and also flower. The hard-pruning keeps the specimens compact.

Fruit Trees Dying Back (F. B. H.).—The trees are badly cankered, the young shoots being affected first, which fact indicates that the disease was in the trees some time back, when they were quite young. The young specimens if not infected when planted, would become so soon after. The roots are at fault and spraying would not do any good. We strongly advise our correspondent to clear away all the trees, as they die, from that quarter and plant shrubs, roses, etc., making a new fruit plantation in another part of the garden. They will not be a success in the present plot—at least not for many years after the soil has been well broken up and cultivated.

Strawberry Plants Failing (F. B.).—The young plants, specimens of which are sent for inspection, are lacking in vigour, and were evidently layered from plants equally unsatisfactory in this respect. The young plants are too hard and stunted to emit roots freely, and our correspondent will do right in making a new plantation. The foliage, even of healthy plants, assumes a bronzy-yellow appearance at this season. Trench the soil 2ft. deep in the new quarters, add half-rotted manure freely, and in the top 6ins. mix with the soil 8 oz. of basic slag per square yard. The ground should be prepared and the strawberries planted as soon as possible. Procure young plants from a healthy, fruitful stock.

Figs Unsatisfactory ("Beechwood").—Early in the growing season all sappy shoots should be pinched out, and this ought to be done till the middle of August, leaving only main branches, most of which will bear young fruits. At the end of July the tips of the shoots bearing figs should be pinched off. In our correspondent's case, judging from the appearance of the fruits sent, this has not been done, and the figs have been overcome by the growth this wet, dull summer. The cherry is the Morello.

Red Currants Unsatisfactory (Miss E. W., Hereford).—The bushes have suffered from an attack of aphides earlier in the season and, being inside a wire cage, birds were not able to assist in the destruction of them. The aphides infest the undersides of the leaves and the latter curl as a result. There is no disease present, but the bushes have suffered a severe check. Apply a good surface dressing of rotted manure in the autumn and lightly fork it in.

MISCELLANEOUS.

Heating Greenhouses (E. P.).—The suggested arrangement of the hot-water pipes should be a very satisfactory one. At the point where the pipes pass from one house to the other they need not be exposed to the weather. Brickbats and mortar built on both sides and a tile or piece of slate on the top would enclose the pipes. The average night temperature in the large house could be maintained at 58° Fahr. in the winter and in the small house at 60° Fahr.; but several degrees lower would do for greenhouse plants in severe weather.

How to Construct Violet Frames (Lancashire).—Taking the surface of the soil as the normal level, the back wall of the frame should be 2ft. high, the front wall 18ins. high, the width, approximately, 4ft. Single brick (4½ins.), will be strong enough for the walls, wood wall plates screwed together and lights about 4ft. 6ins. in width. A hot-bed is not necessary, so soil need not be taken out, but compost put in so that its surface will be 1ft. from the glass. The leaves of the plants almost touch the glass.

Peas, Parsley and Clarkia Unsatisfactory (Mrs. G. S. B.).—The clarkias are attacked by the fungus Pythium de Baryanum. It is present in the soil and affects the roots sooner or later: later when the plants are kept growing early in the season. Apply 6 oz. of lime per square yard in the autumn and leave the soil lumpy or ridged through the winter. Owing to the continuous wet weather the haulm of the peas at the soil level has been attacked by a fungus, Erysiphe Martii. This mildew is very deadly; destroy the plants, burn haulm and roots, lime the ground in the autumn and grow peas in another quarter next year. The parsley is healthy, but suffering from lack of stimulating food. Manure the soil for this crop in future.

Various Questions (D. McC.).—The auriculas thrive in a mixture of fibrous loam, rotted leaf-soil, sharp sand and a small quantity of charcoal dust. They do best in an open position, especially in a border facing north. The border soil or soil in pots or frames should never be allowed to become dry, but in the winter excess of moisture should be guarded against. If given good treatment and sweet soil this should prevent decay at the collar and roots. Do not use the methylated spirit, but an insecticide from a firm advertising in this journal. The spirit would injure the plants. Plants for the rockery: Alyssum saxatile compactum, Arabis albida, Arenaria montana, Aubrietia in variety, campanula, Draba Gigas, Iberis Little Gem, Linum flavum, dwarf phlox, primulas in variety, sedums, Silene alpestris, Statice incana nana, thyme, and Veronica repens. Greenhouse plants: Zonal Pelargoniums, primulas, cinerarias, chrysanthemums and various bulbs for winter and spring; pelargoniums, begonias, fuchsias, achimenes, liliums, petunias, salvias and gesneras for summer and autumn.

Renovating an Old Garden (W. T. W.).—As the garden has been neglected and weeds have become established, there is no more satisfactory way of freeing the soil from them than the one described by our correspondent. Digging deeply not only enables one to get rid of the weeds, but it improves the soil, too. The latter should be left in a lumpy state throughout the winter to mellow and sweeten. The most satisfactory way of treating the sunk portion of the lawn is to remove the turf, fill up and returf. This work should be done as soon as possible if the ground is soft enough. Retain the raspberry canes of medium strength, prune back to 1ft. from the base and re-plant, this autumn, in rows, allowing a space of 9ins. between the canes and at least 4ft. between the rows.

American Cress (L. S. S.).—The young plants of American cress should be thinned to 4ins. apart in the summer and to 6ins. in the autumn. A last sowing may be made early in September. For the benefit of late sowings, an open position is best and the drills should be 1ft. apart. A light shelter of branches in the winter is beneficial. Seeds of nemesia and schizanthus should be sown now.

Roses for Large Bushes in Meadow Grass (E. F.).—The species will be the best for positions described. We suggest that our correspondent plants Rosa Hugonis, RR. Webbiana, multiflora, rugosa, Willmottiæ, sericea, omeiensis and var. pteracantha, macrophylla and spinosissima. A few hybrid bush roses to try would be the Lord Penzance briars, Fellenberg, Homère, Grüss an Teplitz, Lady Waterlow, Blush Rambler, Conrad F. Meyer and Mrs. Anthony Waterer. Unless our correspondent cultivates rings round the bushes and applies an occasional mulch of manure the results will be very poor.

Names of Plants.—(J. M.).—Roses: 1 and 5 had fallen to pieces on arrival; 2, Jessie; 3, Marie Verdier; 4, Mme. A. Chatenay; 6, Pink Provence.——(Miss G.).—Amelanchier canadensis, the Service berry or June berry.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Onions.—The bulbs from the seed sown early in the year will soon show signs of maturity, and those that still possess strong green tops may have these bent over to encourage the ripening of the bulbs. When the crop is lifted it should be thoroughly ripened before being placed in store. The best way to keep them is in a cool, dry shed, damp being the chief enemy of the onion after it is stored.

Beet.—The roots should be lifted directly they have attained a suitable size, and stored in ashes in a cool shed. Break the leaves off, not too near the crown, or bleeding will follow and the roots be thereby robbed of their goodness, while they will also be pale in colour when cooked.

FRUITS UNDER GLASS.

Melons.—Plants that are making plenty of headway, and bearing a crop of fruit, should have all useless growths removed, but this should be done gradually or the plants will receive a check. Other plants not so vigorous or that have become slightly starved may be given liquid manure, and the later crop just swelling their fruits will benefit by a light top-dressing of soil, and a sprinkling of fertiliser. Melons approaching the ripening stage will need less moisture both in the atmosphere and at the roots, but sufficient water must be afforded to maintain the foliage in a healthy condition. More ventilation is allowed, and during a cold, wet spell of weather a temperature of 60° to 65° Fahr. is kept up by warmth from the hot-water pipes.

Peaches.—It is sometimes necessary to root-prune a tree, and if this is required in the early house such work may now be carried out. The tree should be lifted carefully and damaged roots cut back by a clean cut. When replanting add fresh soil such as good loam to which is added a fair sprinkling of lime rubble, lime being very necessary to all stone fruits. Spread out the roots, and make the soil firm, afterwards giving a thorough watering. Keep the trees well syringed with clear water when the weather is fine, and if the sun is hot a little shade will be an advantage until the roots are re-established.

THE FLOWER GARDEN.

Annuals.—The sowing of these useful plants is usually associated with the spring, but excellent results are obtained by sowing a number during the next few weeks. A warm, dry border is most suitable, but they will succeed in all districts except where it is very wet and cold during the winter months. Sow in lines 1ft. apart and when the seedlings are large enough thinning must be resorted to or the plants will be weak and spindly. Among the plants suitable are coreopsis, eschscholtzia, Shirley poppies, cornflower, candytuft, phacelia and numerous others.

Eremuri.—These stately plants are best left undisturbed for several years, but where they have formed a number of crowns, now is a suitable time to divide them. A well drained position should be chosen, and the crowns placed several inches below the surface.

Lilium candidum.—The present is a good time to plant fresh bulbs of this chaste old lily, or to lift and divide existing clumps. Deep planting is not recommended, and where the soil is of a heavy nature plenty of sharp sand should be added. Bold groups are the most effective.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Cabbages.—Plants raised from seed sown early in July should be sufficiently advanced to plant out now. Ground from which early or second early potatoes have been cleared is the right place on which to set out the young plants. Cabbages following potatoes, or *vice versa*, is correct rotation and, indeed, works splendidly in practice. It is said that potatoes are greedy for potash and do not take up quite so much phosphate, and so the ground is left in a most suitable condition for cabbages, as they draw to a greater extent on phosphates. Drills should be drawn 18ins. apart with a triangle hoe, and the plants set out in these at 12ins. to 15ins. distance from each other.

Celery.—The early set out plants should have grown quite tall, and the tying should be taken in hand forthwith. Care should be taken when doing the work to leave all top ties or bands somewhat loose, so that space is allowed for further growth and expansion. As soon as the tying is done and all surplus growths and leaf-stalks cleared away, the plants, if at all dry, should be well watered at the roots, then the earth from the sides of the trenches filled in and around each plant when the stems are perfectly dry.

THE FLOWER GARDEN.

Anchusa Italica Dropmore, raised from seed sown in boxes some time ago, should now be transferred singly into 4in. pots, then set in a cold frame. Before winter sets in the pots should be sunk to the rim in coal ashes, so that the roots of the plants and the pots will be safe in severe weather.

Carnations.—This has been a fine season for good clean carnation growths, and no difficulty should be experienced in selecting shoots for layering. Where the work has not been done or is yet to be completed, it should be forwarded without further delay.

Stocks.—The seedlings of All The Year Round, Brompton and East Lothian stocks raised from seed sown last month should be set out in cold frames or boxes filled with good soil. The compost, when placed in boxes or frames, should be made firm, so that the young plants are prevented from making soft or rapid growth. When once established, keep the frame lights off, so that the young stocks are kept hardy. It is somewhat disconcerting to find that self or home saved seed of East Lothian stocks produces such a large percentage of single-flowered plants. However, if anyone harvests seed from the type known as All The Year Round, they will be charmed with the results, as this kind produces many fine double-flowered plants.

THE HARDY FRUIT GARDEN.

Apricots.—The young shoots to be retained should be tied in so that the trees will present a neat and well kept appearance. This work should be done in such a way that the greatest amount of light and sunshine is allowed to reach the fruits.

Apples.—The plentiful blossom which we were privileged to see on nearly every tree has not given us the gifts we anticipated. Trees such as James Grieve, Mr. Gladstone, Lord Suffield and White Transparent, grown against walls, should now have fruits almost ready for culinary and dessert purposes. The practised eye can tell when the fruits are ready for pulling; but a sure, safe and simple guide is to grip each fruit gently and then slightly raise it upwards: if the stalk parts readily from the spur, then the fruit is ripe.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Malmaison Carnations that have been layered in frames should now be ready for lifting and potting. According to their size and quantity of roots they will require either large sixties or 48-sized pots. The potting compost should consist of a good medium loam that has been stacked for twelve months, and old mortar rubble may be used instead of sand, as lime in some form is essential for all carnations. Unless the loam is heavy I do not advise the use of leaf-soil in the potting compost. The plants should be firmly potted, afterwards standing them in cold frames. If the weather is bright, it will be necessary to keep the frames closed and shaded for a few days until the roots of the plants get a hold of the fresh compost. Afterwards the plants should be given plenty of air on all favourable occasions. Where it is desired to grow on some plants as specimens, good plants should be selected from young plants layered last season. If they are in 6in. pots they will require a shift into 8in. pots. Use the same compost as advised for the young plants. A 6in. potful of fine bone meal may be added to each bushel of soil. After re-potting, the plants should be neatly re-staked and tied.

Hard-wooded Plants, such as greenhouse heaths, may be successfully propagated by means of cuttings at this time. According to the quantity required, small sixties or 48-sized pots may be used. The pots should be nearly half filled with crocks, placing some rough material on the top of them. The pots should then be filled with fine sandy peat rammed very firm, and finished off with some clean silver sand. In selecting cuttings, most beginners make the mistake of using too large cuttings. Very small, half-ripened twiggy side shoots should be selected for this purpose. Trim off the base with a sharp knife; the small leaves are best pulled off, taking care not to tear the bark. With a little practice one soon becomes quite expert at this part of the operation. The small cuttings should then be carefully dibbled into the prepared pots of compost. They should then be well watered in with a fine-rosed watering can. Afterwards stand them under bell-glasses in a cool greenhouse. Although not really essential, a propagating case with slight bottom heat is an advantage. Under perfectly cool treatment they will take a little longer to root. The glasses should be removed for a short time every morning, wiping them dry with a washleather. Most of the hard-wooded greenhouse plants may be successfully propagated by this method. In preparing epacris cuttings the leaves should be carefully trimmed off with a sharp knife, for, unlike ericas, they cannot be pulled off without tearing the bark. The same remark, of course, applies to nearly all other hard-wooded plants. When propagating plants of this class it is a great advantage if stock plants can be kept in the propagating house for some time before the cuttings are required. This applies especially to many plants that are difficult to propagate.

Correa cardinalis.—This beautiful Australian plant, with its drooping, tubular-shaped scarlet flowers, is at present somewhat scarce in cultivation. It is propagated by grafting it on young stocks of Correa alba, a species which roots and grows readily from cuttings. C. ventricosa and its varieties are grafted on the same stock. However, C. pulchella and C. Harrisii can be readily increased by means of cuttings.

J. COUTTS.
Royal Botanic Gardens, Kew.

THE ARRANGEMENT OF CUT FLOWERS

WHEN arranging flowers for table decoration or to adorn the house, the choice of vases or bowls in which to place the blooms is of great importance. Their size, form and colour should be taken into account. Nothing surpasses crystal receptacles, though those made of ordinary glass please the eye. In both the water should be kept absolutely clean—*bien entendu*. If coloured pottery or china is used, green, orange and yellow go best with flowers, and simple designs in blue and pink on a white ground are not amiss. Green is the colour, *par excellence*, for vases, bowls or pots, especially the pale shade one gets in some Dresden china. Bowls of that colour filled with yellow roses, marigolds, orange Californian poppies and Cheiranthus Allionii (the small stock-scented wallflower), are most alluring. In high vases of the same colour lilies, irises and single chrysanthemums are charming, but roses and sweet peas look their best in bowls of all sizes and colours.

Violets and primroses should be placed in shallow bowls or large glass or crystal ones with mirrors beneath them so that the lovely shape and colour of the under part of the flowers may be reflected. Snowdrops are delightful if arranged lightly on moss in soup plates.

High-growing blooms, such as delphiniums, phloxes and giant daisies should always be put in the tallest available vases, their stems being kept as long as possible since height enhances their slim beauty. At the same time each stem should vary in length from its companions and should be put separately into its place. The chief rule with regard to flower arrangement is "to set up the blooms" (as our grandmothers used to say), as nearly as possible as they grow. This implies that tall flowers should never be overcrowded. As lilies, foxgloves, snapdragons and delphiniums expand, their stately stems rise proudly aloof at a reserved distance from their fellows. The small flowers may be massed together with good effect for so they grow. Generally speaking flowers should be "set up" with their own kind only, a mixture of cut flowers being inartistic.

The Japanese, who are flower worshippers and whose educational curriculum always includes flower study (not botany, but the contemplation of flowers as creatures of exquisite beauty of form and colour), and for whom floral decoration is a fine art, always arrange each cut blossom separately in a position which shows off its especial beauty.

Doubtless there *is* great beauty in masses of bloom, but it is less perfect and subtle than that of the single flower. Nature dots violets, primroses, snowdrops and lilies of the valley about promiscuously and we can imitate her. Such flowers and also scillas, crocuses, anemones and hepaticas are charming when grouped together in wide bowls. Strong-scented flowers if placed too near to others cause them to fade quickly, so it is best to have them as far apart as possible in a room. Violet leaves have a curious faculty of nullifying the scent of their flowers if they are placed together, these should therefore be arranged without their foliage. Roses, lilacs and the blooms of flowering shrubs in general, can often be gathered in sprays and arranged as they grow, excessive shortening of the stems being avoided.

The foliage of the flowers themselves is the best to use in almost every case; a notable exception being that of wallflowers, which is insignificant. These should be placed in bowls, their glorious colouring needing no green to enhance it. If, however, they are gathered with long stems, wallflowers may have sprays of dark-leaved maple or copper beech to keep them company. Daffodils are daintily beautiful with their own sword-like leaves, but if they are dotted in among sprays of bog-myrtle they are equally entrancing.

Quality should always take precedence of quantity and a room should never be overflowered. Two beautiful arrangements of cut flowers are often quite enough. No regularity should be observed in the placing of flower receptacles. One high vase on a writing table, a low bowl on a small table, one medium sized vase and one large bowl on the chimneypiece, a tall vase on a shelf corner and a wide low bowl on a table near by: these things give diversity in the room which arrests the attention and satisfies the eye. Like an ill-kept bed or a weedy path in an otherwise tidy garden, one faded flower or leaf spoils the whole harmony of a pretty room, therefore all such should be at once removed.

VICTORIA SLADE.

BOOK REVIEW

SIR JAMES COTTER, BT., has chosen a most ambitious title, "All About the Rose in Simple Language" (Andrew Melrose, London, price 6s.), for his book of 214 pages, and while we cannot say that he has literally carried out his avowed intention, he has given a vast amount of information in a very pleasant and chatty manner. Although Sir James Cotter ventures to express the hope that his book may "help the seasoned rosarian," it is essentially a book for the amateur and, perhaps most of all, for the novice. Throughout the book it is evident that the advice and much of the information freely given is the result of personal experience, and this adds greatly to its value.

Commencing with a brief history of the rose, the author gives very readable descriptions of the different types, with which he includes some of the species. Amateurs, especially those who are young in rose growing, will find the chapter on "Rose Terms" especially useful. Then comes "Rose Gardens," in which it is laid down that three essentials to successful rose growing are: (1) Immunity as far as possible from frosts. (2) Shelter from cold winds. (3) Abundance of fresh air and sunlight. We cannot imagine anyone failing to agree with 2 and 3, but the first is very debatable. If frosts were qualified with "severe" then all would be in agreement, but there be those who, out of their experience, have formed the decided opinion that moderate frosts in winter are beneficial to the rose. If Sir James were right, we should find the best roses in the Riviera districts and the worst in the Midlands and the North. Whereas, generally, the reverse is the case.

While we are at one with the author's insistence on deep digging when making rose-beds, we should like to point out a slight inconsistency. On page 43 we read that "three feet is none too much, four is even better," but the chapter closes with a lucid description of bastard trenching two spits, which are feet, deep.

Sir James is a whole-hearted advocate for roses only in rose beds, and when first-rate blooms are desired this, of course, is the way to obtain them; but quite a number of garden lovers prefer general effect and are content with, perhaps, smaller blooms.

For the winter protection of tea roses in cold gardens a mulching of leaves is recommended. In this there is a danger of harbouring slugs and also, long before spring, the leaves become "soggy" and airtight, so that many prefer to cover the stems with cinders or small coke.

Writing on manures is nearly always treading on dangerous ground, particularly when treating with chemicals. We are inclined to feel that the author over-values manures for roses, especially when he recommends the application of liquid manure "once a week from the time the buds commence forming until the end of the first week in July." Manures and soil are too intimately related to dogmatise. Later in the book we are told that "watering outdoor roses is a thing to avoid as much as possible."

Apart from these details the reader will find much of interest and, as we have previously remarked, the novice will derive a deal of useful information from this book. The paper and type are good, but the illustrations are capable of considerable improvement. The few colour plates are travesties of beautiful roses, and nearly all the line drawings are badly drawn, though they express the author's meaning.

A. C. B.

General Bulb-Growers' Society of Haarlem, Holland.—The different floral committees have made the following awards to herbaceous plants at their sessions from May 26th to July 14th, 1924:

FIRST-CLASS CERTIFICATES.—Delphinium hybrid Dina, single, unicoloured sky blue, eye striking creamy white coloured, spike formed like a pyramid. Iris (Holl) David Bles, unicoloured deep blue, falls in the centre pearl blue, with small yellow spot. Exceedingly stout variety, with big flowers. Iris (hispanica) Golden Lion, dark yellow, falls and standards elegantly waved. Ixiolirion Ledebouri, dark blue, the variety is a fortnight earlier than others, petals are shorter. Pyrethrum hybrid Eileen May Robinson, soft pure pink, large flowers, single.

AWARDS OF MERIT.—Delphinium hybrid Empress Queen, mauve with blue, large spike, semi-double flowers. From seeds by the Nursery Rijnstroom v/h F. Koppius at Alphen o/Rijn. Delphinium hybrid Hortulanus E. Th. Witte, unicoloured mauve with white eye on base of sky blue. From seeds by the late Mr. F. Koppius. Delphinium hybrid Ivorine, ivory white to soft sulphur yellow, large stout spike with soft yellow eye. Delphinium hybrid King George V, violet on a dark blue base, with little black eye. From seeds by the late Mr. F. Koppius. Delphinium hybrid Tutankhamen, mauve on striking blue base and a white eye. From seeds by the Nursery Rijnstroom v/h F. Koppius at Alphen o/Rijn. Delphinium hybrid Princess Elisabeth, light violet with striking bright white eye, middle-sized flower, half filled. From seeds by the Nursery Rijnstroom at Alphen o/Rijn. Iris (Holl.) Heemskerk, unicoloured golden yellow, standards passing into sulphur yellow. From seeds by Messrs. C. G. van Tubergen, jun., at Haarlem. Iris (Holl.) Josselin de Jong, standards white, falls golden yellow with orange blot. From seeds by Messrs. C. G. van Tubergen, jun., at Haarlem. Iris (pallida) Goldcrest, unicoloured deep blue with striking yellow beard. From seeds in England. Iris (Regelio-cyclus) Lucia, violet-red, with striking blue beard. From seeds by Messrs. C. G. van Tubergen, jun., at Haarlem. Lupinus polyphyllus Pink Pearls, warm salmon pink, mild flowering. From seeds in England. Lupinus polyphyllus Tunic, very soft pink, long stem, to be considered as an improvement of L. p. Princess Juliana. From seeds in England. Pyrethrum hybrid Dr. Bosch, colour salmon rose, long stem, free-flowering, little flower. From seeds in Germany. Sedum elegans, leaves grey, on the rockery (dry) grey with brown shades. Resembles Sedum reflexum, aureum and others. Stem does not stoop before flowering. Explorated in Austria. Tritonia crocata Hogarth, soft Isabella colour. Tritonia crocata le Printemps, orange. Tritonia crocata Nectar, creamy coloured, pink shaded. Tritonia crocata Rosalie, bright orange red.

THE GARDEN

ORCHARD GARDEN WOODLAND

Vol. LXXXVIII.—No. 2754 Saturday, August 30th, 1924 Price THREEPENCE

The Kelway Colour Border

is planned for continuity of bloom as well as colour effect. Your garden is of enduring beauty from early Spring to late Autumn, and so continues for several years, as a result of the minimum of cultivation, expense and attention.

These Colour Borders have evolved from many years of experience, and clients get the advantage of securing, amongst other subjects, the world-renowned Kelway Specialities in Hardy Plants.

Send dimensions of space to be filled, and the effect required, stating aspect and soil, and asking any questions. We are only too pleased to advise.

Odsal, Bradford.—"The borders I put in of your plants are doing well and I must say they are the best I ever got."

WRITE NOW to the inventors of Colour Borders:

GOLD MEDAL DAFFODILS

Awarded 60 Gold Medals and 3 Silver Challenge Cups

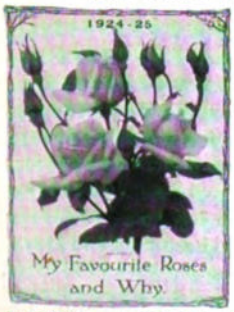
The most complete and descriptive Catalogue of DAFFODILS published; over 400 varieties offered, including many NEW and RARE SEEDLING VARIETIES for 1924. Post free

Also List of NEW HYBRID NERINES, the most beautiful Autumn-flowering plants for the cool greenhouse

BARR & SONS, 11, 12 & 13, KING STREET, COVENT GARDEN, LONDON, W.C.2.

You will, I hope, forgive my questionable method of arresting your attention. The question itself is really one of moment to you.

Do You know ? this Booklet ?



If you know it, there is no question at all about it; you send for your copy every year and wouldn't settle your new list without it.

"MY FAVOURITE ROSES AND WHY" is a text book to give any beginner confidence, but it aims to be a YEAR BOOK and a ROSE ANNUAL that will keep an expert up to date.

Of course it is a Catalogue, too—it wouldn't be free and post free if it weren't; but don't hesitate to write for it because you can never send me an order—if I may say so—it isn't your order I'm after, it is your appreciation.

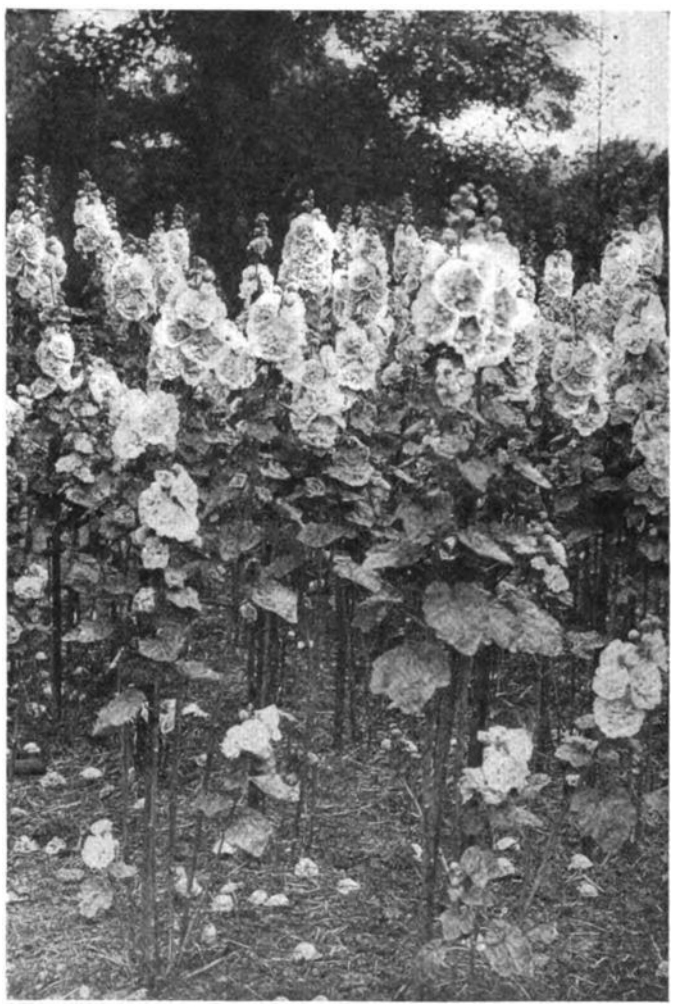
THE GARDEN

VOL. LXXXVIII.—NO. 2754. AUGUST 30, 1924

We would ask our readers to remember that "The Garden" is produced for the benefit of all gardeners. We are always pleased to consider articles or notes on any horticultural subject. We are also here to answer questions. Below will be found details of our Service Bureau which has been instituted to help gardeners in everything appertaining to gardening.



The hollyhock is one of the oldest of cultivated flowers, and, like many old flowers, it is frequently mentioned in poetry and folklore. The strains found in our gardens at the present time are vastly different from the original wild form, the double-flowered and typical garden forms having been acquired under intense cultivation.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

SEEDTIME

IN a vague way my mind has been rambling on for the last hour or so thinking about seeds. My thoughts run like this:

What a good thing that all seeds are not like the ordinary Brazil nuts, which recline in a case so hard that the entire working equipment of a carpenter is blunted in breaking the case open. Botanists tell us that this case is a safeguard against the attacks of insects. *Ergo*, are the mandibles of Brazilian insects less easily blunted than carpenter's tools?

Again, what satisfaction do the Chinese get from eating melon seeds? The kernel is tasteless and is tiny, and yet they extract it with the skill and speed of a dozen parrots and every roadside is littered with the husks in melon time.

The next thought, perhaps not original, is that seeds are the most important things in our lives, and yet in every garden countless millions of seeds are wasted. There is no wastage of energy in the world compared to that of seeds, which are smothered when they fall, or are dug into the ground. No doubt some crank, some day, will measure this energy and try to evolve some scheme for utilising it. Meanwhile, there is no getting away from the fact that an enormous amount of seed is wasted.

This is no incitement to gardeners to collect even a portion of their own harvest, for few realise the immense skill and labour and cost which are necessary for keeping strains of both vegetables and flowers pure. Apart from the mechanical processses of collecting, cleaning, drying and storing seed, the main fact is one of selection. It has been my good fortune, within the past fortnight, to have been shown over the establishment of one of the largest raisers of seed for sale in the world. Here were acres and acres of every conceivable plant being grown entirely for selection of the best strains. The ground was divided into plots of about 8yds. square, each flower separated into its various colours. In order to keep the colours apart from each other, they are separated by some entirely different plant. The result was amazing, and I should advise every large grower of annuals, like gardeners of public parks or gardens, to visit a big seed-raising establishment during July or August so as to see what plants and colours group together. In this particular place there must have been dozens of kinds of phloxes, each one grown in its separate plot, where every variation of tone and colour could be judged clearly and concisely.

As I have said, the labour is enormous. There are men whose sole job at this time of year is to move from plot to plot, pulling out rogues and examining the qualities and defects of each individual plant in the plot. It requires a great deal of skill and patience. The best plants are carefully labelled and numbered for special strains, then the seed is collected and sent out to farmers who actually grow the seed for market the following year, for, large as this extent of ground is, they cannot supply a tithe of what the market can absorb.

This is only given as an instance of the reason why it does not pay the ordinary gardener to grow his own seed. It is really a question of pounds, shillings and pence, for it only pays when it is done on an enormous scale.

On the other hand, there are exceptions, particularly in the case of rare plants or special strains, and in the collecting of such seeds people are often negligent. They say, maybe with truth, that they have sufficient for their own needs; but barter and exchange are important means of acquiring plants among keen gardeners, and a change of locality often does a plant good. I could give a number of instances where plants, not only rare but beautiful, have been lost to cultivation owing to slackness in collecting seed. Many of the new Chinese primulas have proved on first importation to be difficult plants. They are supposed to be perennial, but in many cases they die after flowering. Probably in a generation or two they may become more accustomed to conditions in the British Isles, but gardeners become despondent and neglect to collect seed.

By all means leave vegetable and all ordinary flower seed to those who utilise their knowledge and make their living by raising them, but also keep an eye on anything which is out of the way in your garden, and collect the seed before it is scattered.

POSSIBILITIES OF GARDENING IN SCOTLAND

BY SIR JOHN STIRLING MAXWELL, BT.

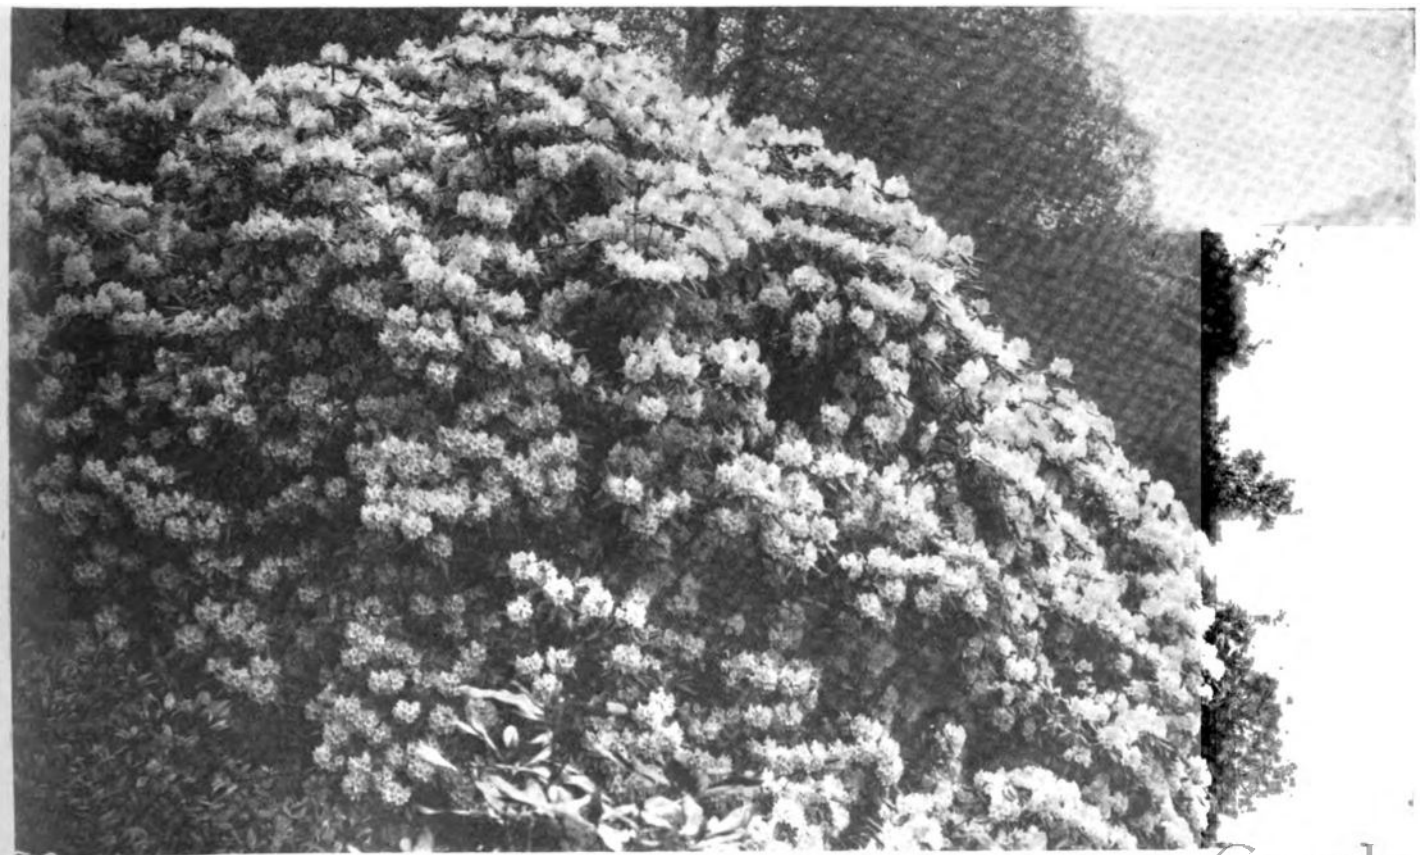
SCOTLAND IS A COUNTRY OF UNBOUNDED OPPORTUNITIES IN THE WORLD OF GARDENING. EVERY PLANT, FROM THE SUBTROPICAL TO THE ARCTIC, WILL FIND A HOME SOMEWHERE IN ITS CONFINES.

THE Editor asks me to write a note on garden possibilities in Scotland—a somewhat bewildering theme since few countries of similar size are capable of growing so wide a variety of trees, shrubs, and herbs or of lending them so becoming a setting. In range of climate Scotland is, of course, surpassed by countries such as Chile, Kenya or Ceylon, where abrupt changes in elevation bring the tropics within a few miles of a temperate, not to say alpine, climate; but in Europe it has no rival as a home for plants, except in the sister kingdom south of the Tweed.

For the culture of such fruit trees and flowering shrubs as demand a hot and dry summer, we must admit that Scotland has few districts to compare with the southern English counties. Yet anything that grows in Hampshire or Kent will thrive as well in the kindly climate of Nairn or Moray, and even in the Lothians and Berwickshire we find at Whittinghame a notable eucalyptus tree and at Marchmont a magnificent arbutus. For plants which dread frost and drought—plants which are only half-hardy in the districts just mentioned—the west of Scotland affords ample scope from Galloway right up to Cape Wrath. Even Cornwall cannot claim a softer climate, and Cornwall lacks the shelter of hills. It also lacks the marked distinction in length of day between summer and winter, which in the north tends to concentrate the period of growth and thus enables tender things to withstand a winter which even the moderating influence of the sea cannot quite cure of caprice. This last point holds good in spite of the fact that very few of the plants we care to cultivate come from latitudes so high as that of the North of Scotland.

It will be apparent to the reader that any attempt to enumerate the fine things which can be grown in Scots gardens would turn these notes into a nurseryman's catalogue. Let our space rather be devoted to special opportunities which Scots gardeners might exploit. First, there is the great opportunity offered by the west coast. Here in a few fine old gardens, such as those at Culzean, Lochinch, Monreith, Ardgowan, Stonefield and Poltalloch, we see how perfectly at home the flora of the Himalayas, Western China and Chile can be made, not to mention many good things from New Zealand and South Africa. At other places such as Benmore, Ardtornish and Poolewe, enthusiasts have more recently brought together fine collections. Here and there a single striking specimen is found, like the large Rhododendron Falconeri at Gairloch. But the number of plants in general cultivation on the west coast is deplorably small. On the Firth of Clyde hundreds of gardens are passed which contain nothing more interesting than golden euonymus and an occasional plant of Escallonia macrantha. The glories of the April rhododendrons are unknown. In June one looks in vain for the tall primulas from China or the lovely family of meconopsis which would both thrive as well and spread as rapidly in these little gardens as in their native mountains. Public gardens such as are found in most of the coast towns would do good service in making these recent acquisitions known and distributing the seed they bear so plentifully. Now that the influence of the Royal Botanic Garden in Edinburgh is to be extended to the Bayley-Balfour Memorial Garden in Glenbranter, where the possibilities of the soft western climate will be fully exploited and brought within reach of the public, one looks forward with confidence to a rise in the standard of west coast gardens.

Secondly, mention must be made of the small glens or ravines which are found everywhere in the Highlands and in several lowland counties—notably Lanarkshire and Ayrshire, which are otherwise rather windswept. These glens offer wonderful opportunities to the gardener. Here as in all sheltered places, the thermometer must be studied and frost-holes avoided. But the escape from wind, variety of aspect, and rapid drainage which such ravines afford, can be used to



A GLORIOUS SIGHT IN THE PASS OF LENY, PERTHSHIRE. RHODODENDRON CAMPANULATUM IN FULL BLOOM, THIRTY FEET HI

Digitized by Google

produce effects quite beyond the gardener's reach on level ground. The writer's thoughts turn to the entrance of a Perthshire glen where plants of Rhododendron campanulatum and R. barbatum have reached the size of trees—a glorious sight in bloom—and, again, to a garden on the Findhorn, where herbaceous plants planted in large masses adorn the steep, sunny bank of that noble river. Quite apart from its cultural advantages and the chance it affords of effective grouping and bird's-eye views, the glen has mystical charms of its own, especially if the sides are tree-crowned — the broken lights, the noise of water, the exclusion of the outside world—which would make the fortune of any pleasance

Thirdly, a word about the gardens of shooting lodges. These are often at quite high elevations. Many lie between the 1,000ft. and 1,500ft. contours. These gardens are not large or ambitious, and too often they are neglected except for a week before the Twelfth. But where they are in charge of a keen and competent man, be he gardener or keeper, they are often quite delightful. Their elevation makes them late, but they make up for lost time in the long days of the northern summer. The writer knows of a garden near the head of the Don where the strawberries are at their best in the first fortnight of September, roses and sweet peas in full bloom and the borders as gay as those of Hampton Court. His thoughts also wander to a little garden at 1,300ft. in Inverness-shire and compare a large patch of Rhododendron kamschaticum, brilliant in June with its red saucers (when the hares have not paid it too much attention), with struggling specimens of the same species under handlights at Kew. Plants which fall victims of our changeable winter are relatively safe at high altitudes where the winter is steady and the spring late. There are thus in the shooting-lodge garden opportunities often unsuspected by the owner for the cultivation of plants which cannot be kept alive in most lowland places, as well as for the whole race of alpines. Here cotoneasters of all kinds flourish amazingly and, given shelter from wind, many delicate rhododendrons. Primula and gentian, meconopsis, anemone and campanula, and many herbaceous plants apt to damp off elsewhere, will be found to survive and increase under these conditions.

A GENERAL VIEW OF GLENBRANTER, THE FUTURE HOME OF MANY RECENT INTRODUCTIONS.

This note, incomplete as it is, cannot altogether ignore the question of autumn colour, a beauty in which Scotland excels, but seldom sufficiently considered in the gardener's lay-out. Here the writer would specially appeal to those whose gardens are among the hills, where grass and bracken turn at the first touch of frost, especially after a wet September, to gold and amber. It is true that nothing is lovelier at this season than the native birch, rowan and aspen. But other glories are within the gardener's reach. I refrain from a catalogue, but I suggest for a beginner, among the smaller trees, Acer rubrum, A. circinatum, A. pictum and the Japanese maples; among shrubs the common barberry, Berberis Thunbergii and Rosa rugosa; among herbs, Spiræa palmata, Saxifraga peltata and Funkia Sieboldii. These, with plenty of Michaelmas daisies, will make any garden glorious in October, but doubly so in a moorland setting, where the whole picture is in harmony.

ROSES FOR LATE SUMMER

THIS IS A TIMELY REMINDER THAT ROSES ARE NOT FINISHED FOR THE YEAR AFTER THEIR FIRST BLOOMING. SUITABLE VARIETIES FOR THIS TIME OF YEAR ARE LISTED WITH FULL DETAILS.

WHATEVER may be our taste in flowers, the rose stands unrivalled as the flower which prolongs the summer and joins it to autumn and, in some seasons, to winter.

Rose growers will remember the autumn of 1923 and how one was able to gather quite good roses until the early part of November, when the sudden frosts brought winter in reality.

Lovers of the rose are no longer content with the rose of summer; a little study and observance of the varieties which are so good in autumn are worth while, because one may plant these with the assurance that, providing we are not visited with a very dry late summer season, we shall have good flowers in normal September weather.

Although a selection of the suitable varieties is an important point, it is also necessary in order to secure good autumn roses to "do them well." When planting, it is not merely a matter of orthodox routine to prepare the soil so that the roses make good growth. Readers of THE GARDEN have been well informed from time to time on the best method to plant roses. Those who have a good rose soil have little trouble beyond deep digging (two spades deep), the manuring of the soil and hoeing; but those who have light sandy soil, or black sour soil, must take more drastic measures to secure success with autumn flowers.

It is well to remember that these late blossoms are obtained through the means of late growth, and we can only get this by a soil condition which makes them grow again after the first flush of summer vegetation. With poor sandy soil, therefore, as well as black peaty and sour soils, it is necessary to take out 2ft. of earth and replace with some of a heavy nature. Nothing is better than turfy loam, if obtainable although good results with the aid of stable or farmyard manure can be got with ordinary heavy soil. Those who are unable to do this can do much by digging deeply (2ft.) and by manuring heavily, both with stable or farmyard manure and bone-meal. The black soils must have a heavy dressing of lime (or ground chalk) applied early in each year at the rate of ½lb. to the square yard.

SUMMER TREATMENT.

Few people appreciate the value of the hoe. It is almost a mysterious tool in the way it works. It should be used after

Digitized by Google

every heavy fall of rain or watering. It should stir the soil lightly every three weeks to maintain a light surface or tilth.

Unless we have a wet summer, liquid manure water two or three times during July, with occasional heavy floodings of the rose-beds, is one of the best things in order to secure this late growth, which brings the flowers. It may be noticed that I use the word "flooding" in preference to "watering," because few people appreciate the amount of water necessary to penetrate a soil which is at all dry, to be of any good to a deep-rooting plant such as the rose.

To penetrate to the roots, not only a quantity of water but time is required. A bed should, therefore, be watered about three times in an evening, after which a trowel should be used to see how far the water has penetrated the soil. If watering is repeated three days running, it is far better than at intervals of two or three days.

In cutting blooms of the first crop we should cut stems sufficiently long to avoid leaving a long, leggy plant, bearing in mind that this is a summer pruning for the next crop of flowers. If we do not cut our flowers, the same remark applies to the cutting of old flowers and seed vessels, which should be removed as soon as possible, for these much retard a new growth.

Material for spraying the new growths should be kept in stock so that it is to hand to use against aphis immediately they are observed, for aphis may quickly spoil the next crop of flowers.

LATE SUMMER AND AUTUMN VARIETIES.

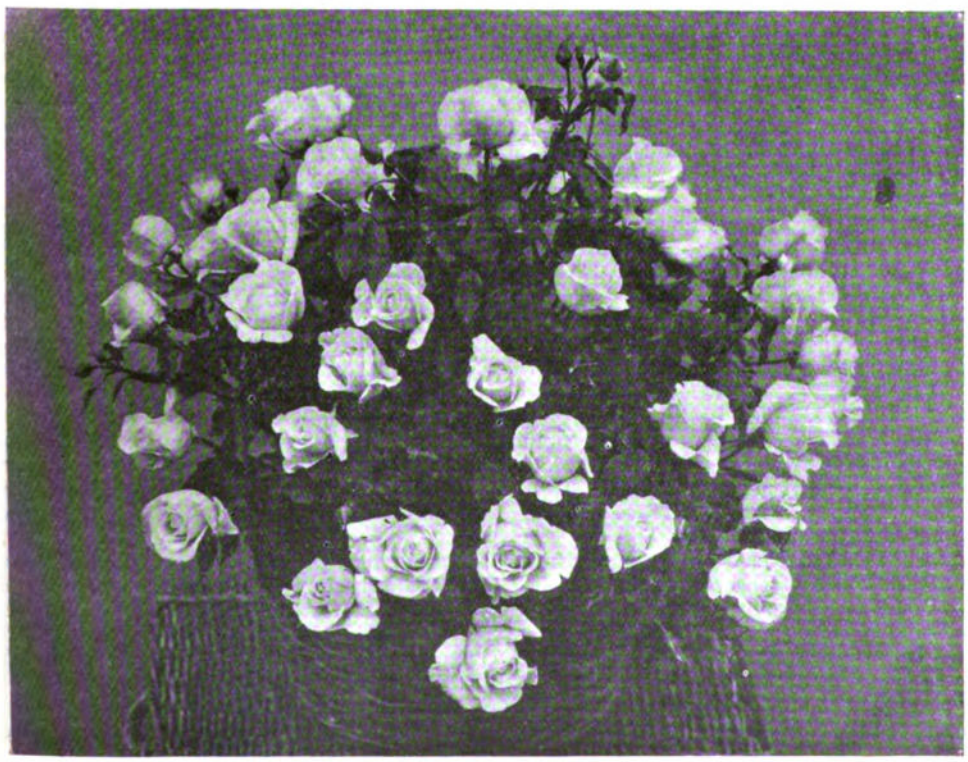
The galaxy of June roses obtained from the old hybrid-perpetual and other summer roses may not be easily repeated, but with a good selection of the continuous-blooming and more perpetual hybrid teas there need be no break of flowers from May until autumn in the south, or from June farther north.

In consequence of the cold summer of 1923, most of the hybrid teas flowered well in the autumn when we had better weather; but a list made last autumn would not be entirely reliable for every season.

Included among the more reliable varieties would be: *Crimsons*—Hadley, Hoosier Beauty and Colonel Oswald Fitzgerald.

Among *Reds*, Queen Alexandra is a remarkable variety that should be included in every garden. A peculiar feature of it this season is that the old gold reverse to the petals is scarcely to be seen. Victory and Richmond are also good, and the newer Etoile d'Holland may be included with its parent, the beautiful General McArthur.

CHRISTINE, OF A DEEP GOLDEN YELLOW, UNUSUALLY FREE AND KEEPS ITS COLOUR.



AN ACCOMMODATING VARIETY OF UNUSUAL EXCELLENCE AND DELICATE TONE OF COLOUR, MRS. H. MORSE.

Of *Rose Pinks* we have an ample choice. That wonderful old variety, Mme. Caroline Testout, would be included, although it may not be everyone's shade of colour. Columbia, Premier, Lady Alice Stanley and a variety I would like strongly to recommend Rose Marie, a lovely rose for the garden, comprise a quartet of varieties that last a week when cut and in water. Mrs. H. Morse may also be included, although this could be classed with Mme. Abel Chatenay, which has never yet been beaten. *Paler Shades* would comprise Ophelia and the more richly tinted Mme. Butterfly.

Among *Whites*, Frau K. Druschki flowers well but less freely than the dainty Clarice Goodacre.

The *Yellow* varieties include Christine, Golden Emblem, Souvenir de Claudius Pernet, Golden Ophelia and its improved form the new Roselandia, also that lovely apricot-tinted yellow, the Rev. F. Page Roberts. Souvenir de Mme. Boullet is another to make a note of.

The *Copper, Orange* and *Apricot* varieties provide a wealth of colour for the autumn. Those who have not enjoyed the richness of Los Angeles or of W. F. Dreer, its half-sister, have a treat in store.

Digitized by Google

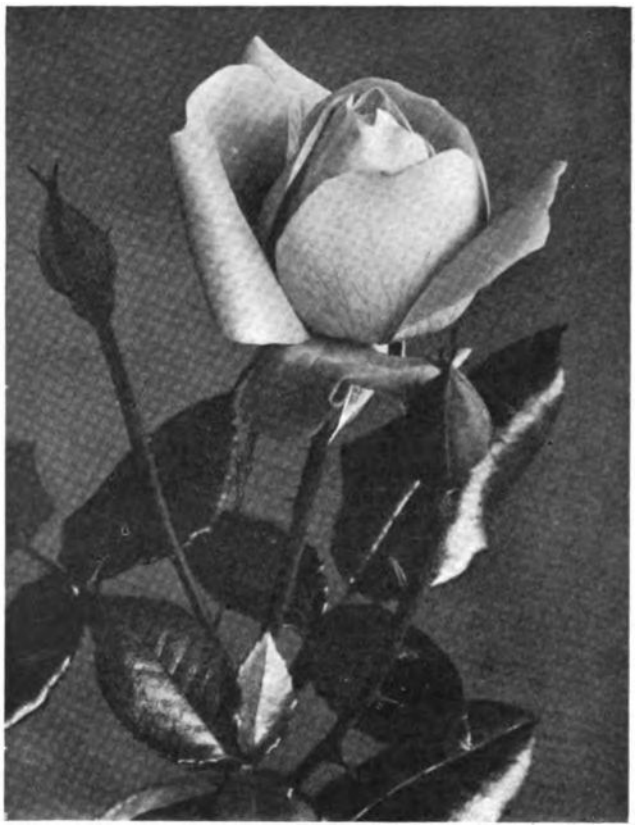
Mme. Herriot, Lady Pirrie and Independence Day are popular ones; while Aspirant Marcel Rouyer, a new rose with an awkward name, has a great future, for it is a greatly improved Sunburst. Those who like singles will find Isobel the queen of this class, her wonderfully tinted flowers are reliable in late summer as well as early.

THE CLIMBERS.

Of climbing roses the rose garden of twenty years ago had few to make it bright. Indeed, on the contrary, there was a sadness as of departed summer while summer was yet with us.

The early ramblers of May and June finished with the Wichuraianas in July, but with the climbing hybrid teas we have a wealth of material to maintain the rose garden gay until autumn in keeping with their dwarf and bush originals.

Our old friend Mme. Abel Chatenay is still to the fore in its climbing form, but if I only grew one, methinks it would be Climbing Paul Lédé, because it grows well everywhere. Its



ONE OF THE SUPREME GOLDEN YELLOW VARIETIES, GOLDEN EMBLEM.

shapely salmon-tinted flowers in summer assume an orange and copper tint in autumn. Climbing Richmond, Climbing Ophelia and Climbing Lady Hillingdon should all be included. For pergola or pillar work Souvenir de Claudius Denoyel is a gorgeous shade of crimson whose deliciously fruity fragrant flowers make it indispensable to all who want the best. Climbing Château de Clos Vougeot is less reliable, yet worth the while of all to try. It is easily the most magnificently coloured dark red rose, blackish crimson with brighter red edge to the petals. Those who can make this rose "do" have their reward where it succeeds. Its flowers hang a week on the plant, and the hotter the sun so much better is the colour it develops, for it never "blues" except in cold wet weather.

Such is a short list of our best friends among roses—those which prolong the glories of summer. There are others, there will be many more to come, but with them we may have roses from May until October.

LAURENCE J. COOK.

THE STORY OF THE ROYAL BOTANIC GARDEN AT EDINBURGH

[This year marks the centenary of the Edinburgh Royal Botanic Garden in its present position at Inverleith. With the exception of Oxford, Edinburgh is the oldest botanic garden in the British Isles. As well as being a botanic garden, it is a great teaching centre under the able directorship of Professor W. W. Smith, since the department of botany of the University of Edinburgh is situated within its confines. Since the days of Sir Isaac Bayley Balfour this garden has specialised in systematic work connected with the flora of China and the neighbouring countries, and it was mostly due to the untiring energy of Sir Isaac that so many magnificent new Chinese plants have found their way into the gardens of this country. A feature of the Edinburgh school to-day is the interest that is taken in the intricacies of plant propagation. No doubt our readers will remember Professor Small's interesting account of the demonstrations which took place at Edinburgh six weeks ago. No visitor to the capital of Scotland should miss seeing these magnificent gardens.—ED.]

THE mere mention of the Botanic Garden at Edinburgh will bring to the minds of many readers of THE GARDEN a vivid picture of an area some 58 acres in extent where may be seen a great spectacle of plant-life assembled from all over the world, each member, one feels, possessing an individuality of its own. And indeed, if one has the good fortune to walk round with the Regius Keeper or the Head Gardener and learn of the way of this plant and of the needs of that, the feeling becomes a definite assurance. Botanists and horticulturists most competent to judge will tell you that the garden is one of the finest institutes of its kind, while the thousands of visitors who pass through its gates testify to the appeal it makes to those who love plants and flowers, perhaps, for their beauty alone.

Yet this extensive collection of plants had but a small beginning, and it may be of interest to give a very brief outline of that historical development which has culminated in the now famous garden of to-day, the present year marking its centenary in the site which it now occupies in Inverleith on the north side of the town.

Most botanic gardens have had their origin in physic or medicine gardens, and that of Edinburgh is no exception. It owes its inception to the designs of Sir Robert Sibbald, an eminent Edinburgh physician of the seventeenth century. Sibbald was intended for the ministry and was sent to the College to study theology; but science attracted him more, and he went abroad in pursuit of medicine. In 1661 he qualified as a doctor in Paris and in the following year returned to Edinburgh and settled down to medical practice. He soon became acquainted with Dr. Andrew Balfour, also a physician, and with Patrick Murray, the Laird of Livingston in West Lothian. Murray was much interested in the cultivation of useful plants and had a good collection of them. When he went abroad, Sibbald and Balfour, by this time fast friends, secured many of them for the purpose of establishing a physic garden in Edinburgh, and in 1670 a small piece of ground at Holyrood, not so large as a present-day allotment, was stocked with medicinal plants, mostly from Murray's collection but partly also from Balfour's private garden. This was the foundation of the Royal Botanic Garden of Edinburgh, the second oldest in Great Britain, that of Oxford, founded in 1632, being the oldest.

Into this small garden at Holyrood the two physicians, together with a James Sutherland, to whom the care of the garden was entrusted, brought together a collection of eight or nine hundred plants. In 1677, the same physicians obtained from the Town Council a lease of a piece of ground situated below the Calton Hill, just where the north-east portion of the Waverley Station now stands. This area they converted into a second medicine garden, known as the Town's Garden, the same James Sutherland being appointed to its charge. Still later, in 1702, the Town College, now the University, founded another and third physic garden at "Kirk o' Fields,"

Digitized by Google

close to the College buildings, and of this College garden also Sutherland became custodian. Thus, in the beginning of the eighteenth century there were three physic gardens in Edinburgh, with Sutherland in charge of all of them. This position brought the man into great prominence, and the University appointed him Professor of Botany, while the King made him King's Botanist in Scotland. Sutherland proved himself an enthusiastic collector of plants, both British and foreign, and had between two and three thousand species under cultivation. As Professor of Botany he gave instruction to students at a fee of £1 per session, and for purposes of teaching he kept a specially arranged border of dispensatory plants. It is difficult to estimate the far-reaching influence which these early physic gardens of Edinburgh have had on the development of science and medicine throughout the world. Certain it is that, with Sutherland as King's Botanist and Professor of Botany, Sibbald as first Professor of Medicine, and Balfour as one of the founders of the Royal College of Physicians, they have given Edinburgh a Botanic Garden and School of Medicine of which she is justly proud.

A PORTION OF THE MAGNIFICENT ROCK GARDEN AT EDINBURGH.

In 1706 Sutherland resigned his charge of the Town's Garden as well as his Professorship in the University, but, remaining King's Botanist, he retained the care of the Royal Garden at Holyrood, and apparently carried also the title of "Regius Professor of Botany." Sutherland's successor was William Arthur, appointed in 1715; but as he became implicated in an unsuccessful Jacobite plot he held office only for a short period, and in 1716 was succeeded by Charles Alston. Soon afterwards the College garden was abandoned, and in 1729 the Town Council gave Alston the charge of the Town's Garden and appointed him Professor of Botany in the University. Thus the Royal Garden and Town's Garden were united under one keeper, and the Regius Professorship of Botany and the University Professorship were similarly combined. The dual post, once again established during Alston's period of office, has so continued to the present time.

In 1763, the Royal Garden and the Town's Garden proving too small, a transference was proposed by John Hope, who had succeeded Alston in 1761, and a new site, about five acres in extent, was secured in Leith Walk. Here the gardens did not remain very long, for Daniel Rutherford, who succeeded Hope, emphasised the need for more suitable ground. The change—not effected, however, until after Rutherford's death—was made in 1820, when the gardens, now under the care of Robert Graham, were removed to 14 acres of ground at Inverleith. The transference of all the plants took fully three years, and thus one hundred years have elapsed since the final establishment of the Botanic Garden of Edinburgh in its present site. During that interval there have been many changes, first under John Hutton Balfour, appointed in 1845, who gradually added to the size of the garden until the present area was completed in 1876, and later under Sir Isaac Bayley Balfour, who held office from 1888 until 1922. It is not too much to say that under him the whole establishment was completely reorganised. Plant-houses that were of no further use were removed or rebuilt and their range greatly increased. Scarcely anything of the old laboratories remains, an almost completely new block of buildings taking their place. The outside garden was entirely overhauled, and a rock garden, Balfour's special pride, created on a grand scale. Truly, Edinburgh Botanic Garden remains a monument to his persistent enterprise and unbounded zeal, a great constructive work which had taken him thirty-four years to complete.

A VIEW FROM THE GARDENS AT INVERLEITH.

In this necessarily brief account, in which an attempt has been made to give some idea of the early beginnings of the Royal Garden at Edinburgh rather than to dwell on later developments, no reference to the principal gardeners has been possible. In the list appear such famous names as John Mackay, George Don, William McNab and James McNab. Their history is another story, and its telling must be left to another time.

J. R. MATTHEWS.

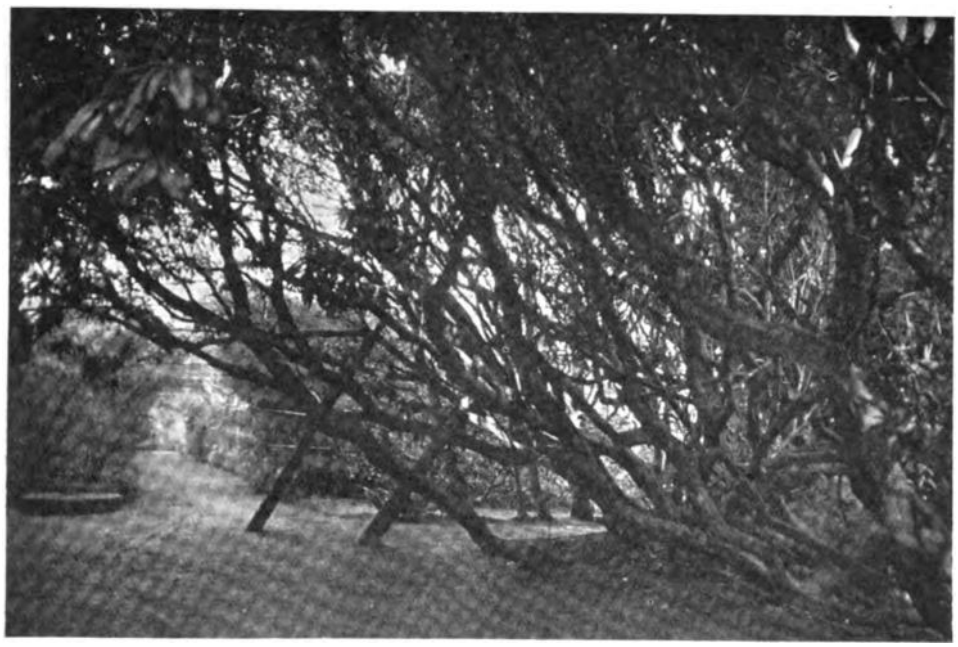
THE GARDEN AT LOGAN

LOGAN, the garden of Mr. Kenneth McDouall, lies on the Mull of Galloway, that narrow strip of land which runs south from Stranraer into the Irish Sea. To those who have not visited that district, Galloway is only known as a wild country where a breed of cows live and which is filled with lochs sprinkled among moors. This is known from Mr. Crockett's novels. What is not generally realised is that Galloway possesses in sheltered nooks and crannies along the coast what must be one of the most equable climates in the world. It is true that last spring they suffered from the results of eight or ten degrees of frost, but that was practically unheard-of previously, and they were not so badly treated by the weather as were the south and west of England. In many years Logan has only a degree or two of frost on the grass on an occasional winter morning, and even that is not common.

In some ways the country and the climate resemble that of Cornwall, but, on the whole, it is more equable and it rarely suffers from drought. The great advantage, from the gardening point of view, that the extreme south-west of Scotland possesses is that July and August are usually damp months and that they are never burnt up by the sun, as is so often the case in the home counties. I was told beforehand about the climatic conditions at Logan and expected to find a great garden, and I was not disappointed.

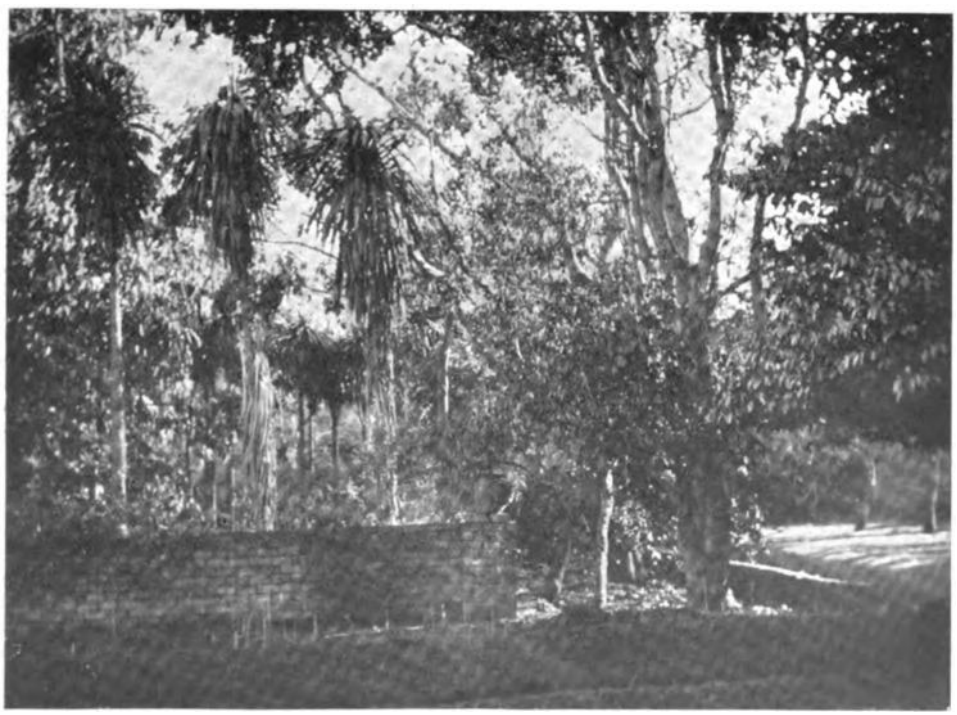


FINE RHODODENDRON HYBRIDS OF GREAT AGE.

Apart from the climate, Logan has one other great advanage. Both Mr. McDouall and his brother are such keen gardeners that they rarely leave home. They are constantly at work in their garden, with that skill and affection which is probably the greatest asset that a garden can have, for the more you put into a garden the greater the result will be—a common aphorism, but a true one.

Logan House faces south-east and looks over Glenluce Bay towards Sir Herbert Maxwell's house at Monreith. To the west lies the garden, and behind that a gently rising wooded slope filled with rhododendrons, and beyond that again the sea. Naturally, as the place is practically surrounded by the sea, there must have been a hard tussle to begin with to keep off the winter gales, which blow there with unexample ferocity; but this has been accomplished by means of hedges and belts of trees, while the slope to the west gives a very fair protection.

One of the first things which struck me at Logan was the fact that here was a garden filled with sub-tropical shrubs, and yet alongside of them roses and other plants which fill gardens elsewhere flourish with equal vigour. This is a very rare combination to find in a garden, and it speaks volumes for the fertility of the soil, for usually roses do not thrive in the moist, clammy atmosphere so necessary for the well-being of sub-tropical shrubs. The rose garden is particularly attractive, enclosed in bays of clipped yew, with taller specimens standing sentinel at the corners. Two of the illustrations to this article show the tropical appearance of this garden better than any number of words. One shows a line of dracænas of great size with two Australian gums of a growth rarely attained in this country, while the other is an illustration taken under some old rhododendron hybrids. This is the true form which the tree rhododendron takes in its native habitat, great branches with clean stems interlacing overhead, forming



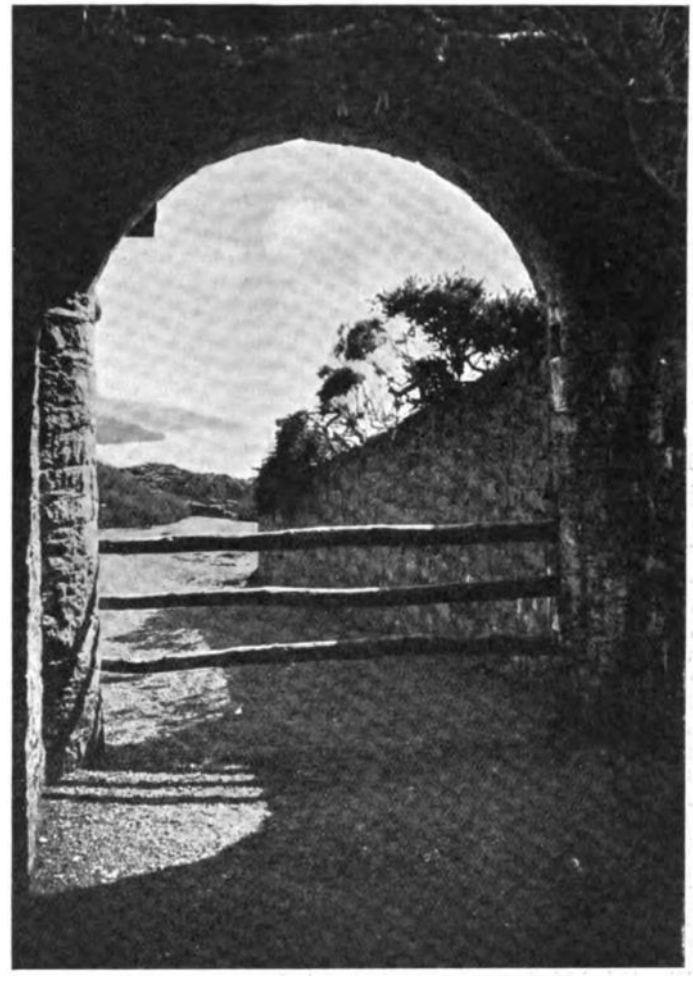
THE TROPICAL APPEARANCE OF THE GARDEN IS SHOWN IN THIS ILLUSTRATION.

Digitized by Google

such thick shade that nothing will grow underneath. It is as well to say that this form of growth is by no means uncommon in this country, but it is only found in situations nearly perfect for the cultivation of rhododendrons. The Himalayan rhododendrons grow particularly well at Logan. Arboreum, Aucklandii, Falconeri are all prominent; but the bush that attracted my attention was one of R. Hookeri: although not the largest, it was the most healthy and shapely that I have seen, and R. Hookeri is usually very difficult. Most of them are planted in the wood beyond the garden. Among the larger bushes straggle those sweet-scented rhododendrons usually seen in greenhouses, such as Maddeni, Dalhousiæ, Edgworthii and their hybrids. They are all completely at home and are as healthy as anyone would like to see [In clearings in the wood and by the side of the drive down to the sea are beds of the newer Chinese seedlings. The illustration shows a portion of a bed of seedlings of R. sino-grande, which is extensively grown at Logan. As a rule, their large leaves are tattered and shrivelled, as this rhododendron is not over hardy; but among all the dozens of seedlings I saw in this garden I could not find any leaf which was not perfect.

Another point wherein Logan differs from Cornwall is that their climate allows them to grow the dwarf alpine rhododendrons with far greater success than in the west of England. At Logan they are grown on the peat terraces, which were described in THE GARDEN of July 26th, 1924, page 519. R. repens was in flower during my visit, and I also saw masses of R. calostrotum and R. myrtilloides, the latter with a mahogany-coloured bell of firm waxy texture, and, to my mind, one of the best of the dwarf rhododendrons.

The fourth illustration shows the western gateway with the road leading down to the sea shore and the fish-pond—and here I must break away from gardening for a moment, for Logan is the proud possessor of what must be the only salt-water fish-pond in the British Isles. It was made many years ago out of a natural cleft in the rocks which is filled at high tide by the sea. Although no longer in use from the food point of view, it contains numbers of large cod and some lythe. The cod are excessively greedy and snap voraciously at limpets held in one's fingers. A cod is not a pretty feeder and gurgles in his gullet when he snaps. Neither is he a dainty feeder, and one has to remove one's fingers in haste, otherwise they will be caught by his exceedingly sharp teeth.



THE WESTERN GATEWAY OF LOGAN LOOKING TOWARDS THE SEA.

To return to the garden. It is impossible to list all the subtropical plants and plants you never expect to see growing and flowering out of doors in Scotland without protection, such as the datura, for such lists only raise envy in the breasts of those not blessed with such a climate as Logan. Although it is the most favoured in this respect, Logan is by no means the only fine garden in the neighbourhood; both Monreith and Lochinch are within a few miles, and they both contain splendid collections of plants. In fact, that portion of Galloway which borders on the sea is full of enthusiastic gardeners: and little wonder, for it is a picturesque corner of Scotland and blessed with conditions suitable for gardening such as could not be found in a Sabbath day's journey.

As this is the time of year when most people from south of the Tweed visit Scotland, it is as well to point out that wherever one travels in Scotland it is a good thing to keep one's eyes open, for, although individual gardens may not be as well known as in England, yet, wherever one goes, one will find keen gardeners and fine gardens. In the east and north they are considerably behind England in time of flowering, so comparisons can be made of the different results obtainable north and south of the Tweed.

FREESIAS FROM SEED

BY THE REV. JOSEPH JACOB.

WE live and learn. Modern ingenuity has made carnations possible all the year round. The potentiality of the freesia as yet is only imperfectly understood. As flowers go, it is a very new comer. One of the best books on bulbs ever published, called "Bulbs and Bulb Culture," by the late D. T. Fish, had nothing whatever to say about freesias. The edition I possess was published in 1885. Even then no mention is made of them, although in Barr's bulb catalogue for 1882 two varieties are listed, viz., Leichtlini at 3s. 6d. a dozen and refracta alba at half a guinea. In the same year THE GARDEN had a coloured plate on July 29th.

Much has happened since then. Freesias are now among the commonplaces of every bulb list. The introduction of coloured varieties—more especially, I think, the yellow ones with their delightful scent—gave them a new impetus. Few in 1882 can have dreamed dreams of the vast development that would take place within forty years. The find of the pinky mauve Armstrongii in South Africa brought in colour. Workers in Holland, Italy, America and Britain began to see visions, with the result that we have the freesia as it is to-day. Yes; but what may it not be to-morrow? From my own experience I think I can say there is a great future before it. We are learning—line upon line, here a little and there a little—slowly learning what can be done by cross-fertilisation and selection. The picture of a splendid potful in full bloom in August from seed only sown the previous March which appeared in Sutton's catalogue for 1923 must have opened thinking gardeners' eyes. That such a thing should be possible! A goodly array of flowers on plants which less than six months before were but seeds! This fact when it is fully appreciated will be found to be a big leg up to its development. No weary waiting of years as in the case of the daffodil! A freesia seed can give us a plant that will bloom as quickly as one from a sweet pea seed!

Will readers forgive my referring to myself? I am sending one of our largest firms ten thousand carefully cross-fertilised seeds this year. It is a straw which shows how the wind is blowing. The wind is zephyr-like now. Before long it will have become a gale—more than a gale, a hurricane, were all Britain the favoured south coast of the Isle of Wight or the warm nooks of Devon and Cornwall. It is no extracting sunbeams from cucumbers to have freesias blooming all the year round. I have three good pots in flower as I write, from corms sent me in March by Mr. Leonard Sutton, and flower-spikes are showing on little plants raised from seed sown last Jaunary. I had some quite decent-coloured flowers this last April from seed sown in July, 1923. Of course, one always gets a small proportion of bloom from seed sown about half an inch apart in seed pans. If, however, one year's experience is anything to go by, one can get good results in the following spring if the seed is sown more thinly in 6in. pots and the plants kept steadily growing on.

To me seedling raising is a great joy. There is a great inward satisfaction to feel that this or that family is like clay in the hands of the potter and that to a very large extent we are able to fashion it as we will. I had visions, when I began, of deep-coloured sweet-scented yellows of an open build. My Flame received the only award of merit given to a freesia this year by the Royal Horticultural Society. I have pure whites which are not far removed from stephanotis in shape and size. It has all been done by seedling raising and selection. Hence it goes without saying that the less time a plant is over its seed production the better for the would-be potter. This acceleration is indeed a "big leg up." How much more can be done in a given time!

To anyone who has a cool, airy greenhouse from which frost can be excluded and who wants a horticultural hobby full of interest and thrills might I suggest the raising of freesias from seed—home-grown, if in any way possible.

LATE-FLOWERING ALPINES

ALPINES which bloom in the later summer are by no means too plentiful; even the commonest kinds are very much in demand at this time of the year, and are also greatly appreciated. To a large number of alpine enthusiasts it seems to be a puzzling question as to what plants can be employed to give colour from, say, July onwards; and, no doubt, it is a troublesome point, as by far the majority of alpines have finished blooming by the end of June. Still, there are a good many, from which a selection is described below, that will prove helpful to readers in search of such information. We should be very grateful to the gentian family, as it provides quite a number of good plants suitable to the title of this note, and which are well worth growing. Some of them may be rather more particular about composts than others, but, I take it, that is all in the game, and in the end the extra time and trouble are often recompensed by good results. However, a good many alpine lovers know the good qualities the gentians possess.

GENTIANA ASCLEPIADEA.—Here we have "the willow gentian," a glorious plant for a cool moist corner in a good peaty loam, and which will grow to 2ft. or 3ft. high where it is suited. It is not difficult by any means, and freely produces graceful, slender stems furnished perfectly with oval pointed leaves arranged in pairs. Its lovely blue blossoms adorn the upper portions of the stems, sitting close in the axils of the leaves. August and September are the months these flowers are borne, when the usual lack of colour prevails in the rock garden. After the plants flower they soon die down for the winter and remain dormant until the following spring. Seed is generally plentiful, but it is rather slow work raising them and growing into flowering size plants; at least three years must be allowed.

GENTIANA SINO-ORNATA is still rather uncommon in gardens, undoubtedly due to its newness, having made its appearance in cultivation only a few years ago. It is one of the loveliest of its race, and of great merit. Flowering in October or so adds additional value to the plant, and for that reason alone it should become extremely popular, and no doubt it will become an "every-man's plant" before very long. Regarding cultural details, I shall suggest and advise treatment that I know to be successful, although I have heard of it thriving splendidly (in numerous cases) in composts that differ from the composts of my own experience. However, I find that a depth of 6ins. or 9ins. of a good mixture of peat, leaf-mould and silver sand in equal parts provides a happy home for this notable plant, in such a position where the sun cannot dry it out. Coolness at the root is a great help towards success. The plant is of prostrate habit almost, and soon makes a mat of dark green leaves, somewhat fleshy and narrow, borne on trailing stems about 6ins. in length; from the tips of these the flowers appear, in large trumpet form, of an Oxford blue shade, beautifully striped on the outside with quaint distinct lines. A close rival to this plant is Gentiana Farreri, very similar in habit and requirements; the colour of its blossoms is more of an electric blue, also striped, with a slightly darker shade on the outside, and the foliage rather narrower and more grassy. Both plants are natives of China, perfectly hardy and perennial, and die down after flowering and remain dormant during winter.

SILENE SCHAFTA.—This charming little plant is worthy of a place in any rock garden, as it hardly ever fails to give the utmost satisfaction with the least possible attention. It thrives in almost any well drained soil and enjoys a sunny aspect. The flowers are a rich pink colour, usually smothering the tufted, slender plant, which grows a few inches high. August being its flowering period causes it to rank among some of the best late-flowering plants. Seeds are readily

Digitized by Google

set, and also germinate with ease, so that, once obtained, there should be no difficulty in keeping up an ample stock to supply ordinary needs.

SILENE CALIFORNICA.—Another item for showy flowers in August, desirous of a warm and sheltered position, in a compost of light gritty soil. It grows about 9ins. high, but the stems are rather lax and are inclined to flop about. At the apex of these stems are borne large solitary flowers of an intensely vivid scarlet, very shaggy and handsome. The leaves are green, oval and pointed. It is rather uncommon in gardens and has the reputation of being a fairly uncommon species, but still it seems to seed and germinate readily.

CYANANTHUS LOBATUS, COOPER'S VAR.—A plant of trailing habit with fleshy leaves and stems, much beloved by the ravenous slug. As an improvement on the old species it has larger and darker blue flowers. They may be likened to those of the "Periwinkle," with round inflated calyx covered with short black hairs. Its leaves are small, green and finely cut at the tips, with a covering of silky silver hairs on the underside. Moisture at root is the key to success, with sunshine; failing this, a cool, semi-shady position is advisable, in a mixture of gritty peat and leaf-mould.

SAMOLUS REPENS.—A quaint carpeter from Australia, needing special care in allotting it its future home. Being a somewhat tender plant, it should be awarded a warm position, sheltered from cold winter winds, in light, gritty soil. It is prostrate in habit, seldom more than a couple of inches high, with tiny leaves of a coppery colour, and abundant flowers in July or August that are almost white, a slight tinge of the faintest pink being present; however, they make a fine contrast to the foliage. Although it is not very showy, and never hits one in the eye, it is quite a dainty little alpine.

ONE OF THE LOVELIEST OF ITS RACE, GENTIANA SINO-ORNATA.

ZAUSCHNERIA CALIFORNICA MEXICANA.—In the late summer this plant blooms in profusion, blossoms of a wonderful scarlet, dangling from slender upright stems of a foot or 18ins. high, and in shape of long narrow trumpets; but it must have one of the sunniest aspects, particularly where it will be kept fairly dry, especially in winter. The foliage is rather hairy and presents a grey-green appearance. The soil should be light, gritty and well drained, and small plants then grow quickly into good-sized clumps.

ŒNOTHERA MISSOURIENSIS.—From late July onwards for several weeks large clumps of this delightful "evening primrose" are seldom without flowers; although individual blooms are very short-lived, there is a good continuous supply always following on. About 4ins. is the diameter of the exquisite, almost sessile, primrose-yellow flowers when fully expanded, but usually they are like large shallow cups, and do not open out as much as is possible. They rise from the axils of the long narrow leaves, which are dark green. The stems are thick and fleshy, dark red in colour, and grow about 12ins. in length, but they do not appear bolt upright—they always, more or less, lie or attain a semi-procumbent habit. It is one of the easiest to grow, asking only for a sunny position in ordinary good loam. For the wall garden it is also delightful.

INULA ACAULIS.—Here is a choice and uncommon alpine, fit for a position in the moraine, where it will form dense low tufts of dark green foliage, not exceeding a height of 3ins. In the late summer numerous flowers appear, stemless, nestled snugly among the leaves, like golden baby sunflowers an inch across. It is perfectly hardy and a sound perennial.

CERATOSTIGMA PLUMBAGINOIDES, probably better known as Plumbago Larpentæ, a typical autumn-flowering plant, is indigenous to China. It requires a warm, light, sheltered position, then it will run about freely underground and soon make a handsome patch of leafage on red stems 6ins. high. The flowers are borne in heads and are deep blue in colour.

Note.—With the exception of samolus and inula, all the plants referred to lie dormant in winter. F. BARKER.

THE CAUCASIAN CATCHFLY (SILENE SCHAFTA) IS WORTHY OF A PLACE IN THE ROCK GARDEN.

FORTHCOMING EVENTS.

September 2nd.—Glasgow and West of Scotland Horticultural Society's Show, to be held in Kelvin Hall, Glasgow (four days).—Croydon Horticultural Society's Meeting.—Royal Caledonian Horticultural Society's Meeting.

September 6th.—Blackburn Horticultural Society's Meeting.—Falkirk Horticultural Society's Exhibition.

COMPLETE MUSHROOM CULTURE

MUSHROOMS all the year round is an impossible ideal, for through the heat of summer it is impossible to grow sufficient to justify the trouble. For about nine months of the year, however, spendid crops result and, by a succession of both indoor and outdoor beds, an unbroken supply is easily kept up.

Growing in the natural way, in a meadow or on the lawn, is a method that is worth much more extended practice, and the time to begin this is in June. It is a very simple matter, and all that is necessary is to lift pieces of the turf, about 1ft. square and a similar depth. Put in 9ins. of fresh horse droppings and ram this as hard as ever you can, then insert a piece of spawn, replace the cut-up turf and again ram well. This is by no means a one-season experiment, for you will gather a splendid crop of mushrooms during the August and September following the insertion of the spawn, and for many years afterwards this will spread and become more and more prolific, far from the original spots in which it was planted. Production in later years may be enormously stimulated by the application of a handful of salt spread over each square yard of ground, which, while it increases the yield of mushrooms, does not injure the grass.

Forcing outdoors from July to April is a very easy matter, if certain methods are observed from the outset The two things most important are the manure and the spawn. The manure should come from horses that are well fed, and too great care cannot be taken in turning and re-turning the heap so as to get rid of all rank steam. While the manure should be sufficiently fresh to ferment freely, it should not be used too fresh, or fermentation may be so violent that the centre becomes white, which necessitates taking down the whole bed and remaking. Throw the manure up into a conical pile and turn it two or three times a week. Plenty of short strawy litter is an advantage, as it tempers the heat, and, if the manure is nearly pure, about one-eighth its bulk of garden soil should be added or there is danger of overheating. Take care, in turning your heap, that the manure which was previously on the outside is turned in to the centre and *vice versa*. Three turnings, as a rule, are sufficient to ensure a proper condition of the manure, but this depends to some extent upon its moisture when received. If very wet, a longer time must be allowed; while, on the other hand, where very dry, it should be damped slightly or it will quickly become white in the centre. Needless to say, perhaps, that steps must be taken to protect the heap from heavy rains while it is heating in preparation for the bed.

Making the bed demands just as much care as the preparation of the manure. Let it be sufficiently large, otherwise it will soon cool, and a great point is to maintain a steady lasting heat. Beat, tread and ram the manure as hard as you can possibly get it, right from the very bottom, and build your bed so that it will be about 4ft. wide at the base, sloping up nearly to a point at a yard high. A thermometer will be necessary to test the heat, for, immediately after making, this will probably rise to 90° Fahr. or more. In a week or ten days this will decline to 80° Fahr., and then is the time to spawn. If the heat rises very considerably, the safest way to cool down is by making several large holes, here and there, through which the excessive heat can make its escape. Do not leave these open too long, or the cooling will be too rapid.

Spawning consists in breaking each brick into eight pieces and inserting these all over the surface of the bed, at distances of 1ft. apart. These pieces of spawn should be inserted perfectly flat, so that there is no air space left behind them, and covered to about the thickness of the brick with manure. The whole bed should now be covered to a depth of 1in. with garden soil, using this sufficiently moist so that it will stick on and not fall off in flakes. Begin this earthing at the bottom and work upwards and, at the top of each spadeful of soil that is packed on, leave a slight ridge so that the soil above will be kept from slipping down.

Having well earthed the bed, the whole should now be covered with a layer of straw to a depth of at least a foot. In about six weeks mushrooms will begin to appear and the yield should continue for three months, especially if, as they become dry, the beds are just moistened occasionally with liquid manure warmed to 75° or 80° Fahr.

Cleanliness of the crop is vastly improved by covering the whole bed with a sheet of canvas before the straw is put on, keeping it in place by pegging at the corners. This also greatly simplifies the gathering, for, where only a straw covering is used, one is very apt to break the mushrooms in forking off the straw. Mushrooms should never be cut with a knife, but pulled out so as to remove the whole of the stalk. Failure to do this leaves the stump of the stalk still in the bed and this rapidly becomes a black lump of decay, which has the effect of killing the mycelium that is spreading in the manure around it and thus prevents the growth of further mushrooms.

The making up of other beds to provide a succession should not be neglected and, as the months advance and we get further into the colder weather, care should be taken to place these in more protected positions and also to increase the depth of the covering straw. Nothing "sucks" the heat from the bed worse than wind, and this is the first point that should be guarded against, by placing the bed at the foot of a wall which gives shelter from the north and east. In very exposed places, the best plan of all is to sink the bed entirely below the ground. Take out a pit and, when the manure is in proper condition, throw it into this, treading as the work proceeds so as to get the whole very firm. Let the top of the bed be about 1ft. below the ground level and spawn the surface in the usual way. It is very easy to place boards over the top of such a bed and bury these under straw to any required thickness, and a bed made upon this plan is usually very productive for a long period. Beds that show signs of becoming exhausted may often be revived by allowing them to approach dryness and then giving a thorough watering with warm salt and water, 1 oz. of salt being dissolved in every gallon of water.

In all cases one can scarcely be too careful as to the source from which spawn is procured, for its freshness is one of the most vital points. Poor spawn is worse than useless and will never produce a good crop of mushrooms. It is not so much a question of age as the conditions under which it is stored. These should be dry and cool, warmth and moisture being the essentials to start the mycelium running. Purchase your spawn, therefore, from a good firm, which has available the best conditions for storage and from which there is a quick sale.

Indoor culture presents no greater difficulties than any of the methods hitherto described, and any building that is well away from the house, such as an old shed or stable, may be utilised with just as profitable a result as in the regular mushroom house. Observe similar care in the preparation of the manure, and see that, while it is sufficiently moist to ferment readily, it is sufficiently dry to have a certain amount of "spring" in it when trodden, as this is just the condition under which the spawn runs most rapidly.

For indoor beds, a foot thick is sufficient, and care should be taken not to spawn until the thermometer tests show that the temperature has fallen to 80° Fahr. Cover the surface, after spawning, to the depth of an inch with garden loam that has been passed through a ¼in. sieve. Keep the temperature about 70° Fahr. by means of the hot water apparatus, if a greenhouse or other building is being used, but in the case of a stable or outhouse maintain the temperature by means of a thicker bed and a deep covering of straw. In the case of a heated house it is better not to use a straw covering, as it has the disadvantages of encouraging woodlice, and also the spawn from the bed is apt to become drawn into the litter. More water will be required in a heated house, but too great care cannot be taken to avoid over-wetness, as this is rapidly fatal to the running spawn. Always use tepid water for moistening purposes and see that paths, walls, etc., are damped efficiently, as well as the manure of the bed. Ventilation on a moderate scale should not be neglected, for it is important to keep the atmosphere sweet, though air should not be admitted in such quantity as to lower the temperature or unduly dry the atmosphere.

Digitized by Google

Where mushrooms are grown indoors, whether the building be an ordinary greenhouse or a shed or outhouse, do not fail to recognise the importance of light in producing results of the very best quality. Where light and air both circulate freely, the mushrooms are thick and heavy, while those grown in the dark are thin and generally lacking in flavour.

Mushrooms may also be successfully raised in pots, but, owing to the limited size of these, the crop cannot be expected to be a heavy one and, owing to the fact that these pots have to be plunged in a bed of fibre, it is much easier to make up a small outdoor bed, which will unquestionably give better results.

Before leaving the subject, a word must be said concerning the various pests that may be encountered. Allusion has already been made to woodlice, and to these may be added slugs and snails, the larvæ of several flies, and, possibly, rats and mice. Slugs and snails are best dealt with by the time-honoured method of trapping by bran or a cabbage leaf. Woodlice will congregate in pots filled with hay and can then be destroyed by turning this into boiling water. Mice and rats should be killed by trapping or virus. Spraying the beds with weak salt and water is the best remedy against the fungus gnats, but care should be taken not to make the surface too damp. H. W. CANNING-WRIGHT.

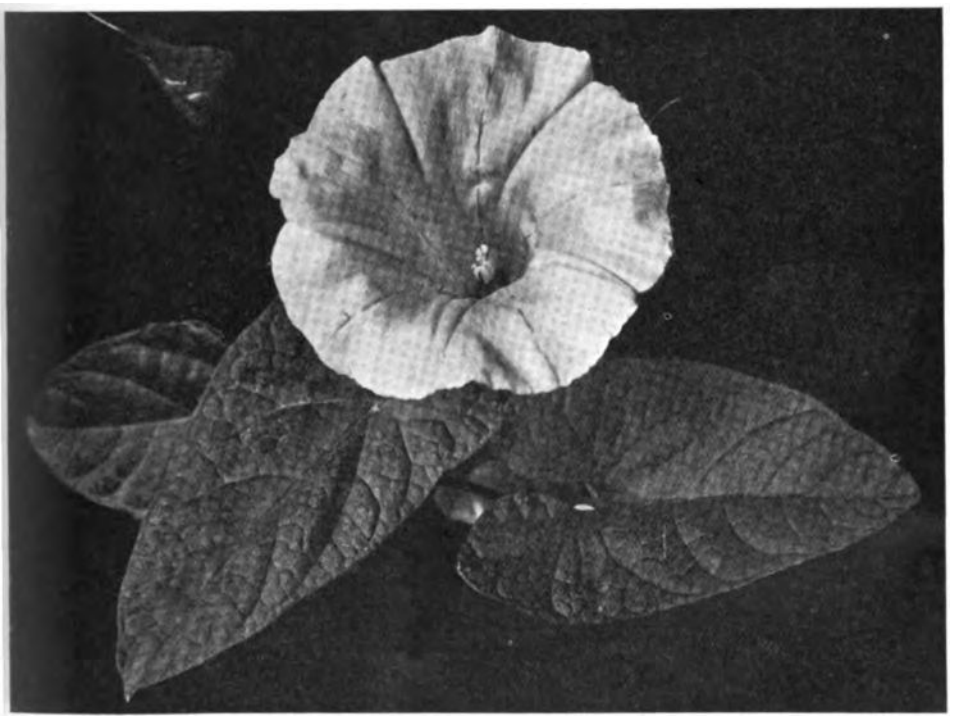
NOTES FROM CONTRIBUTORS

TWO LARGE FLOWERED "BINDWEEDS."

THE ordinary native bindweed (Calystegia sepium) is too common a plant to find a place in gardens, charming though it is. Practically a form of it, but infinitely showier, Calystegia sylvestris, a native of South-eastern Europe and North of Africa, is, however, well worth growing.

The plant is a very strong grower, sending up twining stems over trees and fences up to 12ft. or 15ft. high. During most of the summer, it produces beautiful satiny white flowers, faintly shaded pink on the outside, that measure 3ins. to 3½ins. in diameter, which is at least double or treble the size of those of Calystegia sepium. What makes the species quite distinct are the two large floral bracts, slightly margined with pink, which hide the calyx almost entirely and are conspicuously rounded, with their base ventricose and keeled. The buds are also plump and heart-shaped. The flower is about as long as it is wide, and is borne on a pedicel 4ins. or so long. The foliage is more developed than in C. sepium, distinctly wider at the base and shorter in length. It is generally more lobed at the base and its tint somewhat deeper.

As a whole, C. sylvestris can be ranged among the most ornamental climbers, both for the ordinary or for the wild garden. Nothing more lovely can be imagined than the base of a large Lawson's cypress, dotted, in July and August, with the attractive and large flowers. Anybody who has seen this will long wonder why the plant is not more commonly met with. Its only drawback, like C. sepium, is its invading habit; but provided one is forewarned, measures can be taken to keep it in bounds. The best way is, probably, to build up round the clump an underground fence of tiles or other builders' material, or to keep the rhizomes severely in check every year.



CALYSTEGIA SYLVESTRIS ROSEA WITH BLOOMS OF A DELICATE SOFT PINK.

Beautiful as C. sylvestris is, its variety rosea, a rare form, is still more showy. It has flowers quite as large as the type and of a soft pink. Occasionally one finds it in catalogues under the erroneous name of C. sepium rosea or flore incarnato (C. dahurica), which is quite a distinct and, in the mind of the writer, inferior plant. With it, as with the type, one can make beautiful arches, columns, wall coverings, etc. It can also be used to advantage for climbing up conifers and small trees of strong nature that have a bushy base.

One point not to be missed about these calystegias is to grow them always in a sunny or half sunny and open situation and in soil of fertile nature; otherwise they flower shyly and their blooms do not attain full size and beauty. The propagation of these bindweeds is easy; any tiny underground stem will grow the following season into a new plant, but will, as a rule, show best its second year after it has taken full possession of the ground around it.—C. L., *Paris*.

SOPLEY PARK, HAMPSHIRE.

SOPLEY PARK is the residence of Mr. J. Kemp-Welch, and in the beautiful and well kept gardens, which, practically, surround the mansion, there are many features that arrest the eyes of the visitor, excite his curiosity, arouse his interest and almost tempt him to covet. I had the privilege recently of inspecting these gardens, which are so well managed by Mr. James Murray, the competent head-gardener. To do full justice to these gardens I should have to write a long article, but I only intend to refer to a few features in them that may be interesting to readers. First, I should mention a scheme in blue and shades of blue in a greenhouse. Groups of achimenes, heliotrope, etc., filled the stages, and I have to admit never having seen a more simple combination nor one more pleasing. The old tree carnations were—at the end of July—flourishing still and bearing huge flowers freely. The lawns were lovely, reposeful and a fit setting for the many fine specimen trees. The prevailing colours in the flower-beds were blue and varying shades of it. In a recess backed and flanked by trees and shrubs, and on which the visitor comes suddenly on turning a corner, a rosery has been established right away from other kinds of flowers. Pansies are used as a groundwork, and the general effect is most pleasing. The paths are formed in graceful curves, but in the fruit and vegetable gardens they are straight and tend to the economical working of these quarters where vegetables of all kinds are grown to perfection. The apples and pears are equally well looking, many trees being loaded with clean fruits. Standing out were pear Doyenne du Comice and apple James Grieve. Under glass grapes, including Muscat of Alexandria, peaches and nectarines, figs, melons and tomatoes were huge crops, quality throughout being conspicuous.—G. G.

THE MONTPELIER RUSH.

FEW people know Aphyllanthes monspeliensis, the Montpelier rush, yet it is a plant of high interest in every way and, when it flowers, not to be despised or overlooked, so distinct is it in every way. It belongs, I believe, to the lily family, and comes from the South of Europe and North of Africa. To see it out of flower you think you are looking upon a spreading tuft of rushes of glaucous grey-green and giving no promise of what is to come. By and by, if the conditions are propitious, little brown bud-like sheaths appear at the top of some of these rush-like growths, and then there emerge from these attractive six-rayed flowers of blue. It is quite a delightful plant if you can flower it; if not, it is interesting, but disappointing. In its native lands it seems to seek for a little shelter from the

Digitized by Google

fierce sunshine, and is to be found mainly in partial shade, but in most of our gardens it delights in full sun, although in the south the shade of a shrub is often helpful in inducing this flowering bush to bloom. I have seen it flowering admirably in the garden of a keen grower on the top of a rockwork bank and exposed to all the sun of the day. But this was in a garden near the Forth, and there, as in the North of England, it required all the sun it could secure. This plant grows naturally on rather stiff soil, but with us should have a lighter compost. A rich, deep loam has been recommended, but I think it prefers one of loam and leaf-soil, with or without a little sand, according as the loam is heavy or light. It is frequently long in coming into flower, as it is generally over-divided in nurseries. It hates disturbance, but the economic conditions of a nursery are such that this must be done or it would not pay to retain it in stock. When planted and happy, it should be left alone, and its owner will in time enjoy its flowers.—S. ARNOTT.

THE MIXED BORDER.

THE "thirty acre" gardens which Bacon seems to think the smallest that are worth consideration, and all those delectable rose, rock and herbaceous borders described in horticultural papers, while eminently desirable, are, alas! beyond the reach of those readers who possess only small villas and the grounds thereto attached. These will be well advised to turn their attention rather to the mixed border, which, like genius, shows to most advantage within narrow limitations. It may surprise them to hear what a number and variety of plants may be grown in a patch of ground only 25yds. long and 6ft. in breadth, and how, with forethought and care, a succession of blooms may be maintained in it throughout the year. Thus, a short description of a border of this size may serve as a consolation and suggestion. It is situated in an East of Scotland villa garden and has a southern exposure, and a red brick wall to shelter and form a background to it. On the top of this wall, 5½ft. high, Erinus alpinus, Dianthus deltoides, alyssum, etc., have established themselves. Against it two plants of Senecio Greyii have been placed, one at either end, whose grey leaves are beautiful all the year round and whose great panicles of clear yellow flowers make a fine show in summer. Between those are placed also three freely flowering roses—a Dorothy Perkins, a Conrad F. Meyer, and an old-fashioned nameless white rose more sweet-scented than any of them. In the spaces still left are specimens of Berberis Darwinii, Choisya ternata, Cistus ladaniferus, C. purpureus, Escallonia macrantha, Jasminum nudiflorum, Kerria japonica, Phygelius capensis, Veronica Hulkeana, and Weigela rosea.

The soil of the border is poor and sandy and requires frequent enrichment; in spite of this, the plants thrive wonderfully. The following flowering shrubs, most of them evergreen, save the border from having the bare and blasted appearance of the ordinary herbaceous border during the winter: Cistus algarvense, C. crispus, C. lusitanicus, C. salvifolius, Cytisus Ardoini, C. præcox, Ononis rotundifolia, Philadelphus Avalanche, Spiræa arguta, S. decumbens, Veronica Autumn Glory, V. parvifolia, V. pinguifolia and V. cupressoides. The herbaceous plants are mostly in clumps, but some of them are only single plants. They are Aster Beauty of Colwall, A. Climax, Armeria cephalotes, A. setacea, Anemone japonica Lord Ardilaun, A. Pulsatilla, Anchusa myosotidiflora, Artemisia argentea, Campanula Moerheimi, C. macrantha, Centaurea stricta, Centranthus coccineus, Chrysanthemum Bronze, C. King Edward, Dictamnus Fraxinella albus, Echinops Ritro, Helleborus niger, Helenium autumnale, H. Riverton Beauty, Single hollyhocks, Iris Queen of May, I. pumila violacea, Megasea purpurea, Montbretia germanica, Orobus vernus, phlox red and white, Pulmonaria rubra, Polemonium cœruleum, Polyanthus primulas, Rudbeckia laciniata plena, Scabiosa caucasica, Statice latifolia, Tradescantia virginiana, Thalictrum aquilegifolium, Verbascum densiflorum and V. Weidmannianum.

There are also a few clumps of bulbs—Chionodoxa Luciliæ, Colchicum Bornmülleri, Erythronium Pink Beauty, Lilium candidum, L. umbellatum, Narcissus Queen of Spain, N. Emperor and Muscari conicum.

The edging of the border is made of old whinstone causeway blocks, rising about 4ins. above the gravel walk, and made up behind with stone chips, rough sand and old leaf-mould into a soil suitable for alpines. The following plants fill the ground behind the edging, and some of them grow over it on to the path: Acantholimon glumaceum, Antennaria dioica, Anthyllis montana rubra, Arenaria balearica, A. montana, Aubrietia Dr. Mules, Calceolaria poyrrhiza, Campanula muralis, C. Profusion, C. turbinata, C. Warleyii, C. White Star, Dianthus deltoides, D. cæsius, D. fragrans, Erigeron alpinus, Erodium guttatum, E. Reichardi, Geranium lancastriense, G. Traversi, Genista tinctoria fl.pl., Gnaphalium Leontopodium, Gypsophila rosea, Hypericum olympicum, Iberis Little Gem, I. petræa, Lithospermum prostratum, Mertensia primuloides, Phlox frondosa, P. Nelsoni, Potentilla nitida, P. Tonguei, P. Miss Willmott, Saponaria ocymoides, Saxifraga Aizoon and varieties lutea and rosea, S. apiculata, S. Cotyledon, S. Elizabethæ, S. lantoscana, S. ligulata, S. sancta, S. Wallacei, Scabiosa Pterocephala, Sisyrinchium bermudianum, S. striatum, Silene acaulis, S. alpestris, S. Elizabethæ, S. maritima fl. pl., Smilacina bifolia, Sedum album, S. kamschaticum, S. reflexum, Sedum spurium coccinum, Statice auriculæfolium, Teucrium lucidum, Tunica Saxifraga, Veronica incana, V. pectinata rosea, V. Bidwillii, V. Catarractæ, V. Guthriana and V. pimeleoides.

At present, although the plants are rather crowded, they give little trouble beyond that required to prevent them encroaching upon one another; indeed, some of them have not been disturbed for years, although they all get a top-dressing annually.—H. W. L.

CORRESPONDENCE

THE BREAKING OF TULIPS.

SIR,—In your issue of April 5th, Mr. W. A. Watts made the best contribution to the vexed question of The Breaking of Tulips that I have ever read. When I lived in Dundalk I lost many varieties through this cause, and nearly every variety "broke." It is undoubtedly due to some disease which has the power to live in the soil and so infect any tulip bulbs planted in it. Of course, some sorts are better able to resist this disease than others. Mr. Watts recommends dusting the bulbs at planting time with green sulphur. Does he mean common flowers of sulphur, and could the bulbs be dressed now? I have them in bags. Would it do to put some of the sulphur in each bag and shake up the bulbs?—IGNORAMUS.

[We forwarded the above letter to Mr. Watts, who replies as follows: "In reply to your correspondent 'Ignoramus,' the sulphur I use is the green sulphur generally used for horticultural purposes. It is very fine, finer I think than the yellow flowers of sulphur and therefore better suited to the purpose. I use a little powder distributor, which costs about 1s. at a chemist's, and fill it about one-third full with the sulphur, and give each tray containing the bulbs two or three good puffs before they leave my bulb sheds for the field. There is no reason why the bulbs should not be treated when lifted, and I may say that for many of my other bulbs, such as hyacinths, crocuses, daffodils, etc., I mix green sulphur and insect powder half and half and give a good dusting with this mixture as the bulbs come into the sheds from the fields. If there are any insects or any mould or fungus spores lurking round, this will check them. The amount of powder used is very small, the cost is inconsiderable, the application very simple, and the result, in the case of tulips, at any rate, most satisfactory. Next season I intend to apply the sulphur in the early spring to the young foliage of the tulips with a knapsack powder distributor, with the idea of checking 'fire.' The latter is so apt to appear, after frost or rough weather, on the damaged foliage; but my chief object in using the sulphur on tulips is, as I have previously explained in your columns, to give the bulbs protection from some unknown fungus which I believe to be the cause of 'breaking.'"—ED.]

EVERGREENS IN A FRENCH GARDEN.

SIR,—Will you allow me to ask the readers of THE GARDEN if any one of them will send me some seeds of Piptanthus nepalensis (the evergreen laburnum)? I will, of course, pay for them and the postage. A small quantity will come quite well by post. Some kind anonymous readers of THE GARDEN sent me a great many seeds for "The Little Gardens of Reims." They were greatly in demand. I gave them away as prizes to the more deserving jardinets. I also sold about thirty of the resultant plants at the Kermesse at Reims last year for Les Blessés Mutilés de la Guerre. I could have sold hundreds. Everyone was asking for them. In the garden of the wonderful hospital which has been built by Americans on the outskirts of Reims, in memory of their fallen in the Great War, half a dozen plants of Nepaul laburnum grown from British seed are planted. So are rose trees, gooseberries and currant bushes grown from cuttings sent to me from Windsor Castle Gardens as King George's personal gift to the poor of Reims. Here I am planning a new garden for English people. There is a long stretch of north wall on which I want to induce interesting evergreens to grow. I shall be most grateful to receive any advice from my fellow horticulturists as to what to plant there.—VICTORIA SLADE, 11, *rue de l'Aquette, Grand Vaux, Savigny s Vige, S. et O., France.*

FRAGRANCE IN CALYCES OF RHODODENDRONS.

SIR,—A correspondent in your issue of June 28th draws attention to the fragrance of the leaves of Rhododendron oreotrephes, a quality which, as you point out, is shared by many of the species. One other quality has, I think, been less often noticed: the calyces of some rhododendrons have a distinct and delightful scent. Thus, the beautiful hybrid Lady Alice Fitzwilliam has calyces that smell exactly like the common scented-leaved geranium, though the powerful scent of the flowers is very unlike this. This peculiarity is shared by others of the Edgeworthii tribe and, if I remember aright, by R. ciliatum. Probably some of your readers have noted it in other kinds unfamiliar to me.—W. ARNOLD-FORSTER.

SEEDLINGS AND THEIR PRESENT TREATMENT.

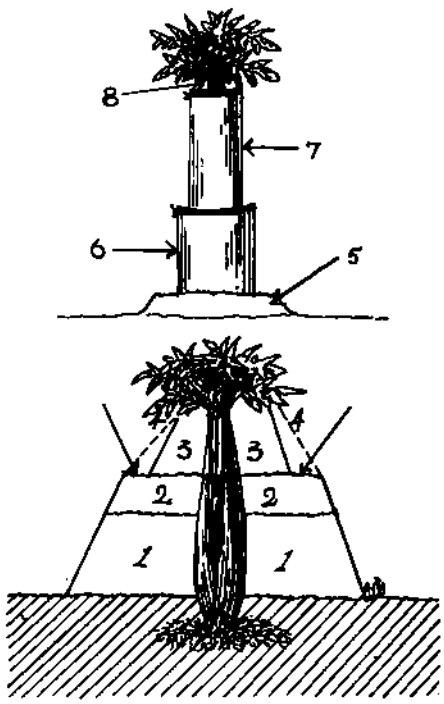
IN the early part of the year, the cultivator who wishes to raise batches of seedlings must meet and overcome many difficulties—late frosts, cold rains, general dampness and insect pests. In the autumn there are difficulties, too, some similar, others not. In the spring, warmer weather and more light come with every day that passes, and if there is a little overcrowding (always a mistake) there is not so much damage done as at this time, when colder weather and shorter days are ahead. So we at once realise the necessity for transplanting farther apart. The question of watering should be duly considered. We have to contend with fogs as well as rain and, later, frosts. Seedlings, now, do not require as much water as they do in spring. If kept on the dry side, it will be to their advantage, and when water must be applied it should be used about breakfast-time, not in the afternoon. In the spring, we try to keep cold winds from the seedlings, and few are placed on high, dry shelves, but nearer the front and middle part of the greenhouse, in the case of those raised under glass. Now, we place them on the high shelves to prevent overdrawing and damping. Seedlings in the open borders should be guarded against earthworms and slugs and the collection of foreign matter among them.

AUTUMN TREATMENT OF GRAPE VINES AND PEACHES.

Many amateur cultivators grow a few vines in a greenhouse structure along with a miscellaneous collection of plants. Such conditions handicap the owner when he tries to obtain that blue-black colour in black grapes and the coveted amber in the white. Even the grower who devotes a structure solely to the vines must act carefully during the colouring process and after the berries are ripe. In regard to the first referred to, all necessary watering of the pot plants should be done early in the day, and if there are stones or tiles as flooring, spilled water should be mopped up at once. Some night air is essential, but only sufficient to keep the atmosphere from becoming stagnant; this is not a difficult task where the hot-water pipes can be warmed at will. A stagnant atmosphere would result in split or decayed berries, or both. In the vinery itself a buoyant atmosphere is easy to obtain. The black grapes colour best under a canopy of healthy main leaves—not a cluster of lateral shoots. The white grapes require full exposure to the sunshine after the berries soften for ripening. Peach and nectarine trees are frequently neglected after the fruits have been gathered. The cultivator should remember that the trees are under glass and, like a chained-up dog, at his mercy. He should thoroughly soak the border with clear water several times, syringe the trees freely, also several times, and night and day keep all the ventilators wide open.

BLANCHING CELERY.

There are several ways to effect a good blanch. The commercial way is somewhat different from that of the private grower. The latter does not mind taking a little extra trouble with his plants in this respect, especially if he requires spotless sticks for exhibition. The two



methods I adopt myself ensure well blanched stems both for autumn and late winter use. My efforts are made towards excluding slugs, which mar the beauty of so many finely grown specimens. Perhaps the sand system will be carefully noted. I like to place sand next to the stalks of all plants for show purposes. Ordinary soil earthing: Nos. 1,1, first earthing; Nos. 2, 2, second; Nos. 3, 3, third. Begin with a wide base; the arrows point to ledges on which the final earthing, Nos. 4, 4, is done and all sides left smooth for the winter. Sand and paper earthing or blanching: No. 5 shows a base of sand; No. 6, broad, stiff paper band; No. 7, top paper band; No. 8, soil and sand, mixed, pressed tightly. The paper bands are filled with sand. Watering and feeding may be continued.

DRYING OFF TUBEROUS BEGONIAS AND GLOXINIAS.

We all like to keep the tubers of these plants sound throughout the winter months if possible, especially those that are expensive or great favourites; but, in spite of all efforts, losses frequently occur. The old plan of storing the pots containing the tubers near to the hot-water pipes should not be followed in these days. It has been responsible for the loss of thousands of good tubers in the past. Even in this case fewer losses would have occurred if boards had been placed between the pots and the pipes and, in this way, prevented dry rot. In the first place, the tubers should be well prepared by gradually drying off the plants and taking care that the old leaves mature naturally before they are removed from the crowns of the tubers. In the meantime, several boxes, a few inches deep and new, should be procured. Peat, leaf-soil or coconut refuse form a suitable material in which to pack the tubers. I prefer sweet leaf-soil free from bits of wood and fungus growths. The leaf-soil should be passed through a ½in. mesh sieve. Place a thin layer in the bottom of the box, then carefully arrange the tubers on the material, leaving a small space between each one. Fill up with the peat or leaf-soil, leaving the crowns of the tubers bare. Remove practically all old soil from the tubers, and store the boxes in a dry place in an intermediate temperature. A greenhouse is quite suitable.

PLANTING VIOLETS IN FRAMES.

The violet is a very accommodating plant. The two enemies most injurious are red spider and damp—especially in the form of fogs. It is not wise to leave the work of placing the plants in frames for early spring flowering to a late date, much better get the plants well established before the short days and cold weather of winter come. September is a good month for the purpose, early in northern counties and towards the end of the month in the southern. The frame should be in a warm, dry position. If a hot-bed is made up, it should be 2ft. wider each way than the frame, and at least 2ft. high after the material has settled down. However, splendid crops of violets may be grown in soil in a frame without any hot-bed material or artificial heat. The soil should be of good quality and sweet — a very important point — and about 1ft. in depth, so arranged that the leaves of the plants will almost touch the glass of the frame-lights. It is an advantage to have the soil in a medium state of moisture.

GEORGE GARNER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Winter Greens.—Such plants as kales, broccoli, savoys and Brussels sprouts are making considerable headway, the season having been ideal for getting them established without much labour. A thorough hoeing will help them, and if the Brussels sprouts are likely to bend over, each plant should be given a stake.

Endive.—A final sowing of a winter variety should be made in lines 1ft. apart, selecting, if possible, a dry border for this crop. Plant out seedlings from earlier sowings directly they are large enough.

Winter Spinach.—The sowing made a few weeks ago should be sufficiently advanced for thinning, and the plants should be about 6ins. apart in the rows. Keep the plot free from weeds, and a frequent use of the hoe is recommended. Where spinach is in demand another sowing should be made.

Celery.—Continue to earth up celery when the weather is dry enough. First remove all side shoots and weeds. The day previous to earthing up, afford the roots a thorough watering with diluted liquid manure. The celery maggot should be watched for, and all brown patches on the leaves picked off. An occasional dusting of old soot will tend to hold this pest in check, and, moreover, it will act as a stimulant for this crop.

THE HARDY FRUIT GARDEN.

Raspberries.—The old canes which have borne fruit this season should be cut out at the first opportunity, and the new growths reduced to five or six on each root. Retain the best and stoutest canes, and tie them singly to the wire supports. All shoots between the rows should be pulled up, weeds removed, and the soil lightly pricked over with a fork. If the plantation has not received any manurial assistance for this year, a mulch of partly decayed manure will be beneficial. At this season the canes should receive as much light and air as possible.

Black Currants.—Overcrowded bushes never produce fine fruit, so it is essential for a little annual pruning to be carried out. The spur system as applied to red and white currants is not suitable for the black varieties, the pruning consisting of merely thinning the old growths that have borne fruit. Encourage the production of strong basal shoots, and if the bushes are now relieved of all useless wood, the new growths will have a better chance to develop to their fullest extent. Plants that are suffering badly from big bud ought to be dug up and burnt, and later on a fresh plantation made on another site.

FRUITS UNDER GLASS.

Pot Vines.—These may now be given a sheltered position outside, but the plants should be fully exposed to the full rays of the sun in order to thoroughly ripen the canes. Plunge the pots in ashes, and the roots should be kept moist until the leaves are fully matured and fall from the canes. The lateral growths should be cut back at intervals to encourage the main bud to develop.

THE FLOWER GARDEN.

The Bulb Order.—This should be sent off as early as possible to avoid disappointment, and with a view of having the bulbs to hand when required.

May-flowering Tulips.—When the bulbs were lifted some months ago, there were found to be quite a number of small bulbils that will not bloom during the coming season. These ought now to be planted out in the reserve garden in lines 1ft. apart.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

French Beans.—The variety Canadian Wonder is usually bearing good crops about this period of the year, but the plants are easily spoiled by frost and early in September a few degrees is sometimes recorded, while the second and third weeks of the month may be quite free from frosts. If the beans are growing on a border, one should fix up a temporary framework of some kind on which a few pea trainers can be laid. Each evening—except if it is raining—spread over the trainers sufficient frame mats to keep the plants safe. By doing a little extra work of this kind one can keep the plants alive and thereby prolong the supply.

Lettuces.—To have lettuces for cutting in winter and early spring the plants should be grown either in a frame or in a sheltered part of the garden. A narrow border at the base of a high wall is quite a suitable place, and seedlings should be set out now 4ins. or 5ins. apart. The cabbage varieties, All the Year Round and Tom Thumb, or Balloon Giant, a cos kind, do quite well out of doors in the winter time.

Onions.—This year—in general—bulbs do not seem to be very large. Those produced from seed sown last autumn should be partly raised now by the digging fork and left thus for a few days. Afterwards they should be lifted and spread out on top of a wall or where they will receive the greatest amount of sunshine, so as to dry the skins and ripen the bulbs. Throughout this period they should be occasionally turned until they are perfectly dry. The bulbs should then be tied up in bunches and hung from the rafters of an airy shed.

Spinach.—The prickly seeded or what is also termed winter spinach should be sown now or as opportunity favours. We have had it sown between the lines of young strawberries as late as September 23rd and obtained splendid results. The shelter which the spinach—when it was fairly well grown—afforded the young strawberry plants seemed to give us the only explanation for the early ripening of the fruits of these strawberries.

THE FLOWER GARDEN.

Ageratum.—Those who like blue shades should grow this old bedding plant, and, indeed, it is not to be despised, as it is so accommodating and even effective when in flower. Those who possess a good compact and floriferous strain should procure cuttings now and insert them in boxes filled with medium fine sandy soil made firm. Give a good watering to settle the cuttings, then place the boxes in a frame and shade from bright sunshine.

Marguerites.—Cuttings of these should also be secured and dibbled into boxes or pots filled with medium fine sandy soil. The double white variety Mrs. Sanders is a choice kind.

Hedges.—The clipping of yew hedges and trees should now be attended to, and it is wise to leave this work to an experienced individual. Well kept golden yews, either in hedge or bush formation, add considerably to brighten and beautify the surroundings.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Nerines, of which there are now so many beautiful varieties, are worthy of much more general cultivation. They only require cold frames and ordinary greenhouse treatment during all stages of their cultivation. N. Fothergilli major is usually the first to show its flowers about this time. The numerous garden varieties will then keep up a display for several weeks. Nerines are generally regarded as being difficult plants to grow successfully, but really their cultural requirements are quite simple. After flowering they should not be neglected, as is too often done. Being their growing season, they should have every attention as regards watering and regular feeding. Where the plants have been in the same pots for a number of years—they usually flower best when left undisturbed for some years—they should be kept regularly watered until the foliage shows signs of turning yellow. At this stage water should be withheld and the plants may then be stood in a cold frame and the lights placed over them to keep them dry. Otherwise they should be fully exposed to the sun or stood on a shelf well up to the glass in a sunny greenhouse. Success depends almost entirely on these two important factors, viz., good cultivation during their growing season and a thorough roasting in the sun when they are at rest. When the flower-scapes begin to show, growth also commences. It is then necessary to give the plants a good soaking at the root, afterwards watering them regularly as they require it. When it is necessary to repot them it is best done when they are just starting into growth. After repotting, water should be very carefully afforded until the plants get a good hold of the fresh compost. The potting compost should consist of a good rich medium loam with the addition of enough sand or old mortar rubble to keep the whole open and porous. A 6in. potful of fine bonemeal may be added to every bushel of soil. It is not advisable to use large pots, and large shifts should be avoided when it is necessary to repot specimen plants. Nerines produce seed quite freely, especially if hand fertilised. Seed should be sown as soon as ripe and the resultant plants grown on without drying off until they attain flowering size, which is usually the third year from seed sowing. Nerine Bowdeni should never be dried off altogether, for, unlike the others, it is more or less evergreen.

Pycnostachys Dawei.—Plants propagated earlier in the year make fine large specimens for the conservatory beds. If cuttings are rooted at this time, useful plants will be produced for the stages.

Coleus thrysoideus may be treated in the same way as the above, plants rooted at this time being very useful for the stages and general decorative work. This coleus can be successfully rooted right up to the time that the inflorescences are beginning to show. Shoots at this stage rooted in small sixty pots are very useful for table decoration.

Lachenalias should now be repotted, the bulbs being sorted out into different sizes. The smaller sizes should be placed in boxes and grown on for next year. Lachenalias thrive in a similar compost as advised for nerines, and eight to ten bulbs may be placed in a 48-sized pot. Stand the plants in a cold frame and give very little water until they start to grow. These plants require perfectly cool treatment at all times, and succeed under the same conditions afforded nerines and freesias. J. COUTTS.

Royal Botanic Gardens, Kew.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Plants for Dry, Sunny Bank (J. H.).—Suitable shrubs include Spartium junceum, Genista hispanica, helianthemums, double gorse, Tamarix pentandra, Atriplex Halimus, lavender (especially the dwarf vera), Santolina Chamæcyparissus, Vinca major, Hypericum calycinum and rosemary. As the locality (Budleigh Salterton) is mild, it will be possible to grow at least a dozen cistuses, including CC. laurifolius, cyprius, Loreti, purpureus, ladaniferus, Hillier's Silver Pink, corbariensis monspeliensis and obtusifolius. Besides the annuals mentioned (poppies and eschscholtzias) portulaca, Limnanthes Douglasii and nasturtiums should be included.

Plants for a Rocky Wall (A. T. A. C.).—There is not much prospect of success with the rock wall as long as the elm roots are allowed to invade it, for they not only impoverish, but also dry it up. It would be best to take up the turf at the top of the wall for a width of 3ft. at least, and completely clear it of roots, then to return the turf on the backward 18ins., leaving the remaining 18ins. as planting space at the top of the wall. Then, every three years at least, the back 18ins. of turf should be lifted and the roots again cleared. For the rocky face and the space above, the best plants would be: helianthemums, both the trailing kinds and the larger H. formosum, santolina, nepeta, dwarf lavender, aubrietias, double arabis, Iberis, pinks, Sedum spurium, and your Sedum spectabile, which evidently needs division. This also would be a good arrangement for colour. At the end, where protection from wind is wanted, some evergreen shrub such as laurustinus or holly would be desirable. For the large shrub bed, good additions would be Cistus laurifolius and C. cyprius, both about 5ft.; Veronica Traversi, 5ft. to 6ft., and the dwarfer V. buxifolia, 1ft.; the golden Cassinia fulvida, 3ft.; the grey-leaved Phlomis fruticosa and Senecio Greyii, both about 4ft.; the two hardy fuchsias, FF. gracilis and Riccartoni; Yucca filamentosa, Staphylea colchica, 5ft.; Olearia Gunniana, 3ft., and O. Haastii, 5ft.; Rhododendron myrtifolium, 3ft., and R. ferrugineum, 2ft.; Hydrangea paniculata, H. hortensis and H. arborescens, all 3ft. to 5ft. For lilies among the shrubs, LL. candidum, testaceum and its beautiful white variety, the scarlet pomponium and chalcedonicum, the orange croceum and umbellatum, the pale yellow monadelphum, the apricot-orange tigrinum and the purple Martagon, with its dark variety Catani.

To Prevent Hydrangea Blooms Turning Blue (W. C., Guernsey).—Evidently, the soil in which the plants are grown contains iron, or the water coming into contact with their roots turns the flowers blue. You should procure some soil—at least for the pot plants—from a district known to be free from iron.

Rose and Other Questions (J. McG.).—With regard to the questions about roses, we advise you to procure catalogues from rose growers advertising in THE GARDEN. In these catalogues you will find everything you wish to know, as the different varieties in the various classes are quite correct for the purpose. The small indentation under the bark, showing when the wood is removed from the bud in preparing it, is natural and not detrimental. Carnations Bookham Yellow, Dora Blick, Gordon Douglas, Sir Galahad, Miss Willmott, Purity—these are selfs. The following are yellow ground fancies: Amphion, Becky Sharp, Bombardier, Fantasy, Gipsy Girl, J. J. Keen, Lord Steyne, Rosamond, Sam Weller and Salome. Isatis glauca is a hardy biennial and is propagated by seeds sown in early autumn. Verbascum phœniceum is a hardy herbaceous plant, perennial, propagation by root division in spring. Boltonia asteroides has pale violet or purplish flowers. You will be able to pick it out from the Michaelmas daisies. Tradescantia virginica is propagated by root division. Plant the harebells and ferns in the autumn, and the heather in clumps when the flowers have faded.

TREES AND SHRUBS

Staking a Thorn Tree (E. F.).—On the side to which the tree is leaning fix a stout forked stake or prop at a good angle to withstand pressure. Place the bottom of the prop on a piece of paving stone to prevent it working into the ground. Fix a piece of old rubber tyre in the fork of the prop to guard against damage to the bark. If it will rest against the underside of a branch close to the trunk so much the better.

Beech Hedge (E. M. C.).—To obtain bushy plants forming a thick bottom to the proposed hedge, top the young plants before new growths commence next spring. Continue to stop the shoots as each 1ft. of growth is made until the required height is reached.

Double Gorse (E. M. C.).—Spring is the best time to prune gorse, but if, when young, the plants make extra vigorous new growths, stop these about midsummer. Remove the dead tips now and also all dead material from the base.

Davidia involucrata (F. B., New York).—This very interesting tree thrives in most soils, growing freely in company with woodland trees such as the beech, chestnut, oak, elm, maple, hornbeam and lime. Davidia involucrata resembles very much in leaf the last-named tree. A damp or peaty soil is not required; a medium rich loam is the best for young trees.

THE HARDY FRUIT GARDEN.

Loganberries (E. F.).—It is usual to loop the vigorous young shoots of loganberries to temporary supports until the old canes have finished fruiting and can be cut away.

Summer Pruning of Fruit Trees (C. H. C.-P., Surrey).—It is advisable to summer prune fruit trees. Young shoots growing from the main stems, if not required to fill gaps, should be cut out entirely. Other, normal, shoots of the current year's growth should be cut back to six leaves or buds from the base. The winter pruning following in due course. It is getting late to do this work, but it may be done forthwith.

The Pollination of Plums (Felsted).—(1) Kirke's Blue is stated by Mr. M. B. Crane, John Innes Horticultural Institute, Merton, to be self-sterile, and to set fruit if crossed with Old Green-Gage or Coe's Violet. (2) Mallard: We can only find a very old reference to this, in which Mr. Sherrard, Mr. Crane's predecessor, states "the Plum is partially self-sterile." (3) Diamond: We do not think this has been experimented with, but it is a notably shy cropper in Kent, even on a plot where it is mixed with a large number of other varieties. (4) Arch Duke, no information. (5) Admiral, no information. (6) Belle de Septembre, no information. We do not think any of these three have been used experimentally. (7) Utility: We do not think this plum has been experimented with, but its early promise of profuse cropping would seem to indicate that it might be self-fertile, like most of the heavy croppers, such as Victoria, Czar, Pershore, etc. (8) Washington: Both Mr. Rawes of Wisley and Mr. Hooper of the S.E.A. College, Wye, place this as self-sterile, and the latter suggests crossing it with Pond's Seedling. As to whether any plum will cross-pollinate any other, in Crane's article, "Journal of Pomology," Vol. III, No. 1, he says that in certain instances, which are probably exceptions, varieties are inter-sterile. We think that with the mixture of trees you have got the question of distance would hardly matter. It is rather more a question of insects. Have you noted hive or wild bees or other insects doing the work? We have not found cordon plums to grow very satisfactorily, especially on unknown root stocks. Plums like to have things their own way, and this is impossible with cordons. We have consistently proved that certain root stocks assist plums in much earlier cropping, which is a factor previously neglected.

FRUITS UNDER GLASS.

Grapes Diseased (W. P. H.).—The berries are badly mildewed. No doubt this has been caused this year mainly by the cold winds. A too dry border or one too wet will also conduce to mildew. The grapes are quite unfit for consumption and should be burned. Thoroughly syringe the vines with "Abol" according to instructions given with each tin. This course would help considerably to prevent mildew occurring next year. Of course, careful ventilation, so as to avoid cold draughts, is very important.

MISCELLANEOUS.

Treatment of Bulbs (E. D., Henley).—Rose President Bouche would tone with Mme. E. Herriot best. You have treated the soil quite correctly; in spring apply 1lb. of sulphate of ammonia and 3lb. of superphosphate per 20 square yards to assist both growth and blooms, also the colour of the latter. Moderate applications of rotted manure would not injure the bulbs. The above artificials may be applied instead. Protection from winds and forenoon sunshine is essential in growing tree peonies. Allow, approximately, 4ft. between the plants. The long exposure of the bulbs of Lilium candidum would harm them very much. They do not thrive if frequently disturbed. Apply a good surface mulch in spring of fibrous loam. Yes, Anemone apennina, if given a little shade and allowed to become established, would do well in rough grass provided the latter was not left to grow and smother it. The same remarks apply to Tulipa macrospila. A clear ring of soil must be kept round the bulbs, and their foliage should be allowed to mature naturally and not cut while green.

The formation of Flower Buds (Mrs. V. Aldershot).—If one knew what plants you have in mind it would be easier to answer your questions. To deal with all plants would require too much space. Many woody plants form their flower buds mainly in the previous autumn, herbaceous plants form theirs on the new growths in spring; but the process of flower bud formation is going on all the time, from one year to another. The plant sent for identification is Artemisia vulgaris, "mugwort."

Various Questions (W. M.).—Delphinium Zalil should flower well in your district (Aberdeenshire) if the plants are strong and grown in a deep, rich soil. Sometimes slugs destroy the leading shoot before it is 1in. long, and the secondary shoots fail to flower. Place old coal ashes 1in. deep on and around the crowns in winter. Plenty of room should be allowed for the willow-like stems of Ansonia salicifolia to ensure ripening and flowers. Ordinary deeply dug soil will do. Olearia Haastii is quite hardy; grown in a comparatively sandy soil in the south, the plants flower four

Digitized by Google

of five years. In heavier soils in the north they frequently flower every other year, after very hot summers two years in succession. It is not possible to say what accounts for the poor growth of peonies without knowing treatment of plants. Herbaceous peonies are fond of moisture. The Moutan peonies like some protection in spring, and decomposed manure for all, preferably cow manure. This manure answers well for the Japanese irises; we advise a good trial, and also plenty of moisture for the plants generally.

Names of Plants (Miss C.-B.).—Roses: 2, Moschata alba; 4, Pink Provence: 5, Marie Verdier; 7, Zenobia, moss; 8, Mousseline, moss; 10, Old Damask; 11, White Provence; 12, Charles Lawson; 13, Dawn; 15, Old Cabbage Provence; 16, Double White Briar. Nos. 1, 3, 6, 9 and 14 had fallen to pieces on arrival.——(" South Saxon ").—Taxus baccata, common yew.——(" Shotley ").—Roses: 1, Eclair; 2, D. Jamain; 3, Captain Hayward; 4, E. Morney; 5, Mrs. S. Clarke; 6, Augustine Guinoisseau; 7, Mrs. George Shawyer; 8, Philadelphia Rambler.——(Miss R.) Acanthus longifolius.

RULES FOR THE ROSE COMPETITION

A list of six (only) hybrid tea roses to be sent in in order of preference on a separate sheet of paper, with name and address of the sender clearly written on the top. No ALTERNATIVES WILL BE ALLOWED, but readers may send in any number of lists.

Lists must reach this office not later than Saturday, September 20th (after that date no lists will be accepted) and must be accompanied by a coupon, which will be found on page ii. of this issue. Coupons will also be found in the issues of September 6th and September 13th.

The popular vote will be final, and no correspondence will be entered into over this competition.

Envelopes must be marked COMPETITION and addressed to THE GARDEN, 20, Tavistock Street, Covent Garden, W.C.2.

The Editor will not be held responsible for letters missing in the post.

The First Prize will be an order for £3 on any advertiser to be found in the pages of THE GARDEN.

The Second Prize will be an order for £2 on any advertiser to be found in the pages of THE GARDEN.

The Third Prize will be a book, or books, from the *Country Life* Library to the value of £1.

The result will be announced in THE GARDEN in the issue of October 11th.

The Editor's decision on all points will be final.

See THE GARDEN, *August 23rd, page 578.*

PEONY PLANTING

A FACT that merits far wider recognition among the gardening fraternity is that everything has its proper planting season, and—although we may do this at other times without absolute disaster—yet, when the work is done at the correct time, far speedier and better results are ensured. In no case is this more true than with the peonies—especially on the score of speedy establishment, for no plant likes removal less. Ever a favourite in the hardy garden, the Old English forms have given place to a new race of hybrids of glorious beauty, the petals of which vie with the finest of sea shells in delicacy and beauty of colouring, while—in many varieties—they compete with the rose in exquisite fragrance.

Their dislike of removal must be emphasised from the point of view of soil preparation—this cannot be too thorough, and care should be taken that some of the supply of manure provided is of a permanent character. Basic slag and half-inch bones are two valuable substances that should not be forgotten in this respect, although plenty of well decayed animal manure should be used in addition. Mix this with the soil, right from the bottom, and we may remark in passing that the ground intended for growing peonies should be trenched at least 3ft. deep. Planting, of course, must not be done until the ground has had time to settle, and this means that it must be prepared some time in advance.

Position is an important point. The shrubbery—although so commonly used—is one of the worst possible places. Not only do the hungry shrub roots draw heavily upon the available nutriment, but the tops of the peonies die to the ground level in autumn, thereby leaving large gaps that give an unsightly appearance to the shrubbery in winter. An open but half shaded spot is the ideal, for here the flowers last longest and retain their colour best, a consummation that is impossible of achievement where fully exposed. The old crimson form bleaches to an unpleasant pink in a few days under hot sunlight and the dainty pearl pinks, etc., of the modern varieties are far more fugitive. Writing of the old crimson form reminds that this *is* a plant that will grow under trees, etc., and seems to be quite unaffected by their proximity, but the choicer forms must be planted in the open.

Do not wait until the tops have died down, but complete your plantings before the end of September. This may sound rather unusual advice, in view of the fact that—with most perennials—they are allowed to remain as long as possible before cutting down, but an examination of the roots will disclose the reason for this. Just beneath the surface of the ground, next year's shoots, buds, leaves, etc., are already formed and more is gained by sacrificing the foliage now than in allowing planting to be deferred.

September planting means that those roots will already have begun to work before wet and cold stop further progress. October or November plantings simply remain dormant until the spring and then have to start upon their work of re-establishment. Do not bury the crowns too deeply, 2ins. below the surface is about right, and—while making quite firm—be sure not to bruise the growth buds. Plants should never be put nearer than a yard apart, for—once established—growth is very luxuriant and they will fully cover that area.

Next March and every one that follows, mulch the plants heavily with manure, for this serves a threefold purpose. First, it retains moisture in the soil; secondly, it keeps the plants cool; and thirdly, it goes far in providing that nourishment without which handsome flowers cannot be produced. It is during the early part of the season that any extra nourishment is of the greatest value, for no sooner is flowering past, than the plant turns steadily to the business of producing the following year's shoots and buds. Do not feed during the first year after planting, the ground will contain plenty of nourishment from the initial preparation, but, in subsequent years, a few thorough soakings of liquid manure during dry spells will be amply repaid.

Vol. LXXXVIII.—No. 2755 Saturday, September 6th, 1924 Price THREEPENCE

The Kelway Colour Border

The formation of actual scenes of beauty with living subjects abounding in interest individually would seem to be a pleasant and worthy amusement, and one as full of dignity as the portrayal of such scenes on paper or canvas.

The late Dean Hole truthfully wrote in *Our Gardens :* "There has been no introduction which has had such happy and universal influence in extending and increasing the enjoyment of a garden as the HERBACEOUS BORDER." One of the first remarks of one's hostess in the country nowadays is, "Would you care to see my new Herbaceous Border ?"—or "my new KELWAY Border ?"

Send dimensions of space to be filled, and the effect required, stating aspect and soil, and asking any questions.

WRITE NOW to the inventors of Colour Borders :

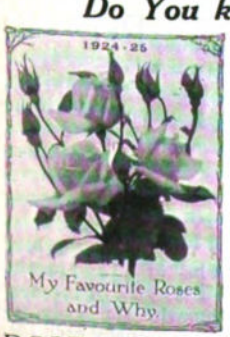
Also List of NEW HYBRID NERINES, the most beautiful Autumn-flowering plants for the cool greenhouse

BARR & SONS, 11, 12 & 13, KING STREET, COVENT GARDEN, LONDON, W.C.2.

You will, I hope, forgive my questionable method of arresting your attention. The question itself is really one of moment to you.

Do You know ? this Booklet ?



If you know it, there is no question at all about it; you send for your copy every year and wouldn't settle your new list without it.

"MY FAVOURITE ROSES AND WHY" is a text book to give any beginner confidence, but it aims to be a YEAR BOOK and a ROSE ANNUAL that will keep an expert up to date.

Of course it is a Catalogue, too—it wouldn't be free and post free if it weren't; but don't hesitate to write for it because you can never send me an order—if I may say so—it isn't your order I'm after, it is your appreciation.

SEEDS AND PLANTS FROM OVERSEAS

I.—SEEDS.

ON the opposite page will be found the first of a series of articles by Dr. Cockayne on "New Zealand Plants for the British Isles," in the introduction of which he comments upon the fact that many New Zealand plants are difficult to grow in the British Isles. Several of my friends who are expert seed raisers have told me that New Zealand seeds as a rule are bad germinators. That may partly be due to the fact that a great proportion of the New Zealand flora is strictly endemic, but apart from that a great deal of biological work remains to be accomplished to elucidate what goes on inside a seed prior to germination. To a gardener all that matters is "Does a radicle appear or does it not?" but the problems dominating the germinating qualities of seeds have never been really discovered. It seems to be certain that a plant in the prime of life will bear seeds with a higher percentage of germination than either a very young or a very old plant, this, of course, only in the case of ligneous or perennial plants. These remarks, however, only come into the scope of this article in that they show that the question of germination can be approached from various angles.

The usual reasons for poor germination of seeds coming from abroad are as follow:

1. Endemic nature of the plant.
2. Unknown conditions of original habitat and climate.
3. The power of germination is short lived.
4. Chemical action taking place owing to violent change of temperature.
5. Postponement of sowing and careless cultivation on their arrival in this country.
6. What might be called unnecessary packing.
7. Errors in collecting.
8. Mere cussedness on the part of the plant.

Now let me try and explain these reasons in detail with possible suggestions of remedy—if I can think of any:

1. It is natural to suppose that, if a plant is endemic in a confined area, as in New Zealand, it will strongly resist interference even in its seed, particularly as many parts of the world have strongly marked climatic characteristics which cannot be imitated elsewhere. Who can hope to imitate the conditions under which Primula sonchifolia grows, damp summers and a covering of snow in winter, out of which it appears in the spring?

2. This is often fatal to successful germination and is usually the fault of the collector in not providing adequate field notes. The salient facts to be learnt are altitude, climate, soil, orientation, shade, neighbours, temperature. Many failures could be avoided if these details were given in every case.

3. If this is the sole reason for failure, there is little remedy except to get the seed home by the quickest possible route and to sow it at once. Magnoliaceæ are typical examples of seeds whose germinating powers are short lived.

4. About this little is known, but chemical action undoubtedly takes place. In order to counteract any action Kingdon Ward has tried sending home seed in tins filled with carbon di-oxide by means of a sparklet syphon with no water in it, and then hermetically sealing the tin. The result was successful, but it may have been due to an especially good batch of seed and not the carbon di-oxide. Further experiments will have to be made before this is proved.

5. This is also a grave error, entirely due to carelessness at this end. More valuable introductions have been lost owing to postponement of sowing than from any other cause. The best rule in all cases is to get the seed into the soil at the earliest opportunity whatever the time of year may be. The only possible exception could be with a few annuals.

6. As Dr. Cockayne points out, it is a mistake to pack seeds in sand or charcoal. I have never heard of their being any the better for it, and there is no knowing what the desiccating powers of charcoal may accomplish in a really hot climate. It would be better to hermetically seal the tin or pack the seed in clay. This latter method has been tried in the case of oaks with considerable success.

7. It is obviously unfair to expect a collector to have a thousand pairs of hands and be in a hundred places at the same time. It is also obviously unfair to expect all plants to wait for the collector before perfecting the ripening of the seed. I should put 20 per cent. of the failures down to the seed not being collected absolutely ripe. Another error is in collecting seed from young or old plants. There is another moot question. Should seeds with fleshy coatings have the flesh removed or not before sending? There is no doubt that on some occasions seeds only germinate after having passed through birds or beasts, but no doubt they often germinate just as freely when the flesh rots on the ground. The argument against sending seed with the flesh still covering it is that fermentation must set in, and that this may cause a chemical reaction inside the seed, but it appears to be natural that the flesh should rot and that fermentation would take place on the ground in any case. This problem has not been solved as yet.

NEW ZEALAND PLANTS FOR THE BRITISH ISLES

BY DR. L. COCKAYNE, F.R.S.

NEW ZEALAND PLANTS ARE SUPPOSED TO BE DIFFICULT TO GROW IN THE BRITISH ISLES. DR. COCKAYNE, IN THIS AND FOLLOWING ARTICLES, DESCRIBES PLANTS WHICH HE CONSIDERS SUITABLE FOR OUR GARDENS.

INTRODUCTORY.

THE main object of these articles is to give an account of certain New Zealand plants worthy of a place in the gardens of the British Isles, and while dealing with some fairly well known flowers, not to neglect others—frequently of great merit—rare or absent in horticulture. Evidently, too, a knowledge of the conditions under which the plants grow is naturally of horticultural importance, and as so much that is misleading has appeared on this head in garden literature, some general statements may be welcomed concerning the climate of New Zealand. Special details about their actual growing places will be found in the account of the species themselves.

Since the New Zealand botanical region extends through twenty-five degrees of latitude (29° to 54° south lat., the Kermadecs to the Macquaries) there are considerable differences in climate in proceeding from north to south. Thus, in the lowlands there is a gradual change from a frostless winter to one where it is occasionally 16°F. The latter temperature is far lower than many of the forest and coastal plants can endure, so, generally, species of this class are unsuited for the British Isles, except in those localities with exceptionally mild winters. On the other hand, there are about 950 high-mountain species, 490 of which do not descend to the lowland belt. The maximum cold which the last-named class has to endure may be estimated at about 10°F., an estimate derived principally from the behaviour of many of its species under cultivation during specially severe winters both in their native land and Great Britain. These high-mountain plants, then, are those which specially concern gardens in England, Scotland and Ireland, and with such these articles chiefly deal.

TYPICAL VEGETATION ON ANTIPODES ISLAND, ONE OF THE NEW ZEALAND SUB-ANTARCTIC ISLANDS.

ALPINE CONDITIONS IN THE SOUTH ISLAND OF NEW ZEALAND.

Snow does not lie so long as on the European Alps.

Regarding temperature in general, those extremes which occur at similar latitudes in the Northern Hemisphere are wanting at every altitudinal belt: it is only at a few places (these in the South Island) that shade temperatures occasionally reach 100°F. The means for the North and South Islands respectively are, for the lowlands, 61° and 59°, while the winter means are 49° and 43°.

An important factor affecting the plants is the frequent and excessive high winds; those from the south-west, generally accompanied by driving, cold rain, rapidly reduce the temperature. Where this cold, wet, southerly weather rules (as in Stewart Island, and the groups of very small islands far to the south or east of the South Island — the Snares, Lord Auckland, Campbell, Macquarie, Antipodes and Chatham Islands—the first four known as the "New Zealand Sub-antarctic Islands") much of the soil consists of sopping wet peat some 30ft. or more in depth. In parts of the South Island, too, especially in the extreme south and south-west and on the wetter mountains, many desirable plants grow under semi-subantarctic conditions. An important result of such is the persistence of dead leaves and other parts which remain attached to stems, or leaf-bases, as rotting, extremely wet masses into which short roots frequently penetrate. This condition makes these plants difficult to cultivate.

The rainfall, usually spread over many days, differs considerably in different parts of New Zealand, but over wide areas there is ample for the natural incoming of forest. On the west of the South Island, and extending over the Divide,

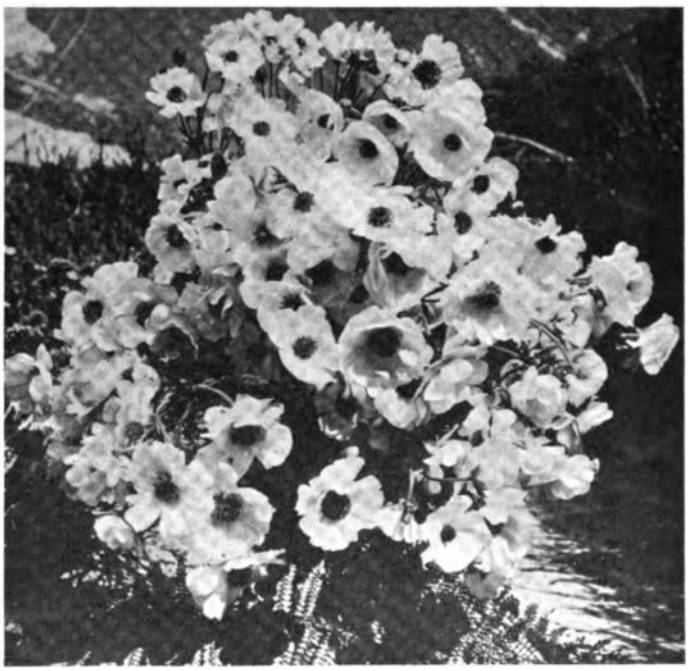
Digitized by Google

the annual rainfall may considerably exceed 250ins. On the other hand, in several localities there falls yearly less than from 24ins. to 14ins. The plants of these semi-arid districts have, likewise, to endure hot, dry, violent winds.

Snow, even in the lowlands of the South and Stewart Islands, may lie, during particularly cold winters, for a day or so, but with increasing altitude it gradually increases until the highest peaks carry vast snowfields, and great glaciers descend to low altitudes (2,500–700ft.). Although a snow covering is a protection against frost, many species subject to its shelter at high altitudes are also abundant where snow lies for a brief period, so they are exposed to continuous frost for many days, or alternately thawed and frozen daily.

PROCURING PLANTS FROM NEW ZEALAND.

Leaving out of the question those species readily procurable from nurserymen in the Northern Hemisphere, undoubtedly the best method of introducing new or rare species is by means of seed. *The essential condition is that such be fresh; seed more than one year old should never be used.* Seeds should always be sown as soon as possible after arrival. Many, even those of alpines, germinate rapidly in gentle heat. There is not the slightest need to pack seeds in dry soil, charcoal or sphagnum, as so often demanded. My personal experience with seeds of thousands of species sent from botanic gardens of most countries has proved that germination is almost certain; my sole failure, after many attempts, having been with Dryas octopetala. Living plants, if properly packed, travel well in Wardian cases. I have often thought that more use should be made of the cool chamber on ships, or of light freezing. Possibly the latter would enable rhizomes, with the flowers already developed, of the glorious Ranunculus Lyallii collected in early spring to travel successfully to Great Britain. The plants would blossom soon after arrival, as do imported bulbs with us, or they might be kept frozen until the European spring. The experiment demands a trial for, if successful, one of the most desirable plants in the world would be available, and cheaply, for British gardens.



A MAGNIFICENT GROUP OF RANUNCULUS LYALLII.

Dr. Cockayne suggests that wise use could be made of the cool rooms on board ship to bring such glorious plants as these alive to the British Isles.

SPECIES SUITABLE FOR GARDEN CULTURE.

The species of New Zealand flowering plants, ferns and lycopods number about 1,800, and, if the two last-named classes be omitted, 80 per cent. are purely New Zealanders. This high degree of endemism, coupled with the unusual forms of many species, makes the New Zealand flora of peculiar value for horticulture. Nearly all the trees and shrubs are evergreen, while plants which yearly die down to the ground are the exception, so there are many evergreen semi-woody species admirable for winter embellishment of the rock garden. In what follows not merely beauty of flowers is taken into consideration, but desirable leafage, elegance of form and use as carpet plants for bare soil. With but few exceptions, the species cited are those which have to endure the most severe frosts that New Zealand can supply. The many fine evergreen trees and shrubs known to be hardy only in the frostless parts of the British Isles are not dealt with; it is those suitable for rock gardens which receive special consideration, and even of these many have to be omitted.

Although in what follows something is generally told about the natural growing places of the plants, it may be taken as an axiom that, no matter in what situations they grow in nature, nearly all the species will do best in good, free garden soil, and that for alpines perfect drainage, abundance of water, and for some (but varying with the locality) more or less shade, are essential. Because a plant grows naturally in peat or in a bog it does not say that peat should of necessity be added to the soil or that the bog plant should occupy a particularly wet spot; indeed, it may do best under dry conditions.

(*a*) SEMI-WOODY PLANTS AND HERBS.*

1. Acæna (piripiri; lowlands to 3,000ft. and some species far higher; stony ground, shingly river-bed).

All make pretty carpets of feathery foliage, differing in colour according to the species. The nomenclature in British gardens is far from accurate; indeed, in nature the species hybridise greatly, and botanically many distinct plants are brought together under one name. The following are good: A. microphylla (A. novæ-zelandiæ of many British gardens) is of various forms; all have showy red spines on the fruiting head. A. inermis has no spines; its leaves are from pale green to slate coloured, dark purple and brown, according to the variety. A. saccaticupula and A. hirsutula are worth introducing. The lowland species (A. Sanguisorbæ and varieties and the true A. novæ-zelandiæ) become garden weeds.

2. Aciphylla (speargrass, Spaniard, little Spaniards).

Many of the species are fine decorative plants with rigid, pale or yellowish bayonet-like leaves. A. maxima (giant Spaniard, 3,000–4,000ft., in the sub-alpine scrub) has flowering stems more than 10ft. high and leaves in proportion. A. conspicua (3,000–5,000 ft.), another tall plant, has orange-coloured midribs. A. pinnatifida (3,000–5,000 ft., wet ground) has smallish rosettes flattened to the soil of narrow, much-cut leaves with yellow midribs, and forms considerable patches by means of its far-spreading underground stems; it is a most desirable plant. So, too, are the small palm-like rock plants of high altitudes—A. Monroi, A. divisa, A. similis and A. Spedeni.

3. Anisotome (Ligusticum in "Manual of the New Zealand Flora").

These are mostly noble plants of the carrot family with long, broad, erect, much-cut, bright green leaves and flowers bunched in large heads. The sub-antarctic A. latifolia, with immense heads of blossoms, rosy lilac, rosy purple, pale lilac, occasionally white, on massive stalks, 3ft. high, and thick, dark green leaves, 2ft. long, is one of the glories of the flora. A. antipoda (also sub-antarctic) is similar, but rather smaller, the leaves more finely cut, and the colour of the flowers richer. A. Haastii and A. capillifolia (3,000–5,000ft. in deep soil in full sunshine) have pretty fern-like, erect, soft leaves and white flowers. A. intermedia and A. Lyallii (coastal) are larger than the last two, but, though easier to grow than any of the above, are not so hardy.

(*To be continued.*)

* My thanks are due to Messrs. Whitcombe and Tombs, Ltd., for permission to draw on my recently published book, "The Cultivation of New Zealand Plants" for matter used in these articles; nevertheless, nearly all are published here for the first time.

Digitized by Google

THE CULT OF THE PENTSTEMON

THERE IS HARDLY A MORE USEFUL PLANT TO BE FOUND IN THE GARDEN THAN THE PENTSTEMON. A TIMELY WARNING IS GIVEN IN THIS ARTICLE THAT THEY FLOWER MOST PROFUSELY IN FULL SUN.

THE name pentstemon covers a wide range of plants that are both hardy and half-hardy, although it is the latter that are more generally met with in the average garden. How satisfying is their colour mass, whether employed in beds or borders, and at how small a cost in labour all this is produced. The hardy species are chiefly interesting to the rock gardener, but here, again, there is no lack of beauty and interest, while one or two, at any rate, are so good that their promotion to the border will provide a magnificent display of charming flowers over a period of several weeks.

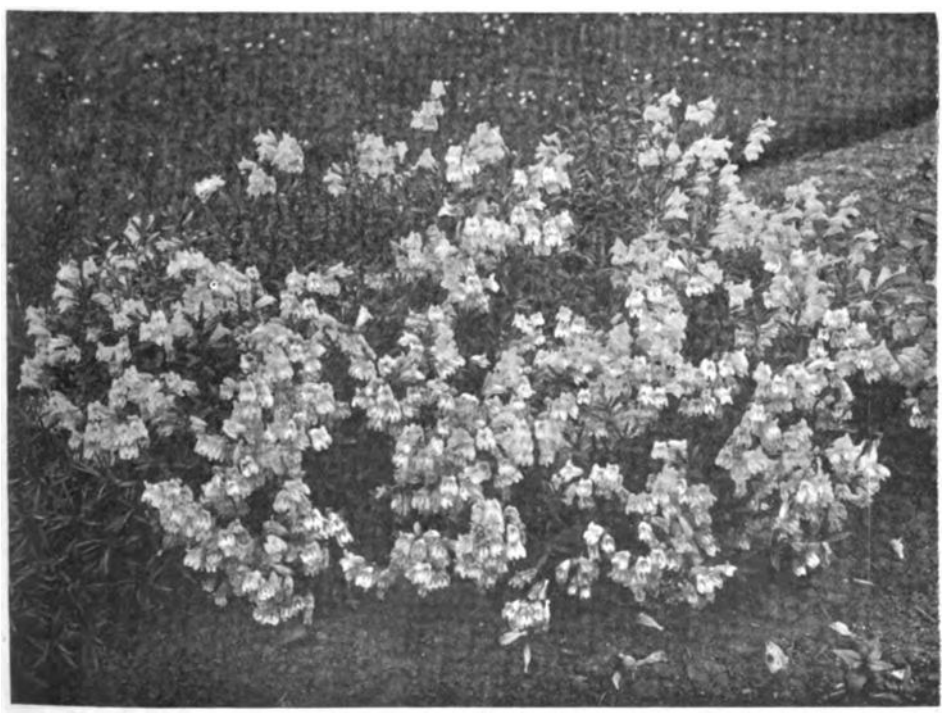
In considering their culture, let us suppose that it is spring and that it is proposed to obtain a stock of the bedding kinds by means of seeds. The plant is a very easy one to raise by this method, and early sowing in a cool greenhouse will give you a large supply of plants that will flower during the same summer and autumn. They will, of course, be a mixed bag, and only the finest forms should be retained for future propagation, but what a wealth of colours and markings one will have from which to select. There cannot be any cause, at least, for complaint at lack of variety; that has been our experience when dealing with the plants in this way.

Having, then, brought your plants to the flowering stage and weeded out the less pleasing forms, future propagation of the best is ensured by means of cuttings. This presents no more difficulty than seed raising did, and a cold frame of average size is sufficient to shelter several hundred plants. The cuttings consist of healthy side-shoots snapped off, either with or without a heel, and when the lower leaves are removed, are at once ready for insertion. This may be done quite close together, for but little growth will be made during winter. The soil of the bed under the frame should consist of a sandy loam mixed with some old manure and leaf mould, pressed down rather firmly round the cutting. Water these well in and then keep the light closed for a fortnight or so, until the leaves stand up without drooping when air is admitted.

A FINE MASS OF ONE OF THE SPLENDID NAMED KINDS, DAYDREAM.

From mid-September to early October is the best time to take these cuttings, as the side shoots are usually late in making their appearance and seldom attain sufficient length before this time. During winter, abundance of air should be admitted. The plants are hardier than the calceolaria, and every effort should be directed towards keeping them dwarf and stocky. Roots are usually emitted in spring, so that the plants are better undisturbed until they show signs of renewed top growth—generally in April or early May—when they may be lifted and planted out where they are to flower, in rich, light and plentifully manured soil. To gain the full effect from them, the plants must be massed together in fair numbers. A note should be made that they are great sun lovers and are quite unsuitable for positions where they do not enjoy a generous share, throughout the greater part of the day, for, deprived of the sun they often fail to do anything but produce stems and leaves.

Before parting from the hybrid forms let us add the following list of a dozen splendid named kinds. Adonais, rosy magenta with pure white throat; Andromeda, salmon pink, the throat blotched with carmine and scarlet; Arethusa, purple lake with white throat; Black Knight, deep maroon blotched with black and maroon coloured stems; Daydream, pink and white throat; George Home, enormous scarlet flowers with white throat; Ideal, white slightly tinged rose; Lucie Farquhar, claret crimson, throat white pencilled with purple; Myddleton Gem, a grand bedder in delicate pink, with pure white throat. This is one of the longest-flowering varieties and will bloom from June 1



PENTSTEMON SCOULERI, WITH ITS PALE LILAC FLOWERS IN GRACEFUL RACEMES.

Digitized by Google

November. Newbury Gem, a compact dwarf grower with small crimson scarlet bells, capable of magnificent effects in the mass; Racine, purple violet with throat blotched with brown; White Newbury Gem, counterpart of the above, but pure white.

Turning to what may be called the hardy kinds, one meets a most diverse range of plants of which many are of great decorative value, revealing an extremely wide range of colours and habits that may make showy effects in the border as well as the rock garden. One uses the word "hardy" concerning them with a certain measure of reserve, for, where a variety does prove an absolutely hardy plant in one garden or district, it may prove quite the reverse in another, so that, until one has tested during several winters, wisdom dictates that a few cuttings should be inserted in a frame as a reserve in case of accident.

P. argutus has well been named the graceful pentstemon, for it produces, in summer, splendid spikes of bright purple flowers, with the tips of the divisions of the lower lip touched with sky blue. The growth is half shrubby, with dark green leaves that are much paler on the underside. Height 3ft. to 4ft. Acuminatus is best suited to the rock garden, as the growth is not above 1ft. The growth is sub-shrubby, with spikes of densely crowded flowers that open lilac and gradually change with age to a deep purple. Barbatus is synonymous with the plant known as Chelone barbatus, a very brilliant and vigorous perennial—6ft. high—of unquestioned hardiness. The flowers are borne in late summer, scarlet on the outside and white within. The leaves are slightly glaucous, the flower spikes drooping in long, rather loose panicles. The variety hybrida differs only in its colour, a purplish violet. Campanulatus is much dwarfer, reaching a height of 18ins. and upwards, and flowers from May until stopped by really hard frosts. This species has been largely used in hybridising the seedlings from which our best named varieties have come and, as it is a native of Mexico, a question mark may well be placed against its hardiness—in all but very sheltered gardens. The flowers are a dull rose on the outside, but light flesh within veined by violet.

Cobæ is certainly not hardy, and one can only be sure of the plant where cuttings are annually inserted. The flowers, which are produced in July and August, are a deep purple and curiously inflated, reaching a height of 1½ft. Cœruleus is splendid for the rock garden, where it makes a neat shrubby little bush covered with narrow glaucous leaves and delightful little spikes of pure blue flowers. Confertus introduces a distinct colour change, for the flowers are pale yellow: the height is about 1ft. and the habit very neat and compact.

Glaber, too, is especially good in the rock garden for the habit is prostrate and the growth does not exceed 6ins. to 9ins. in height. The flowering season is chiefly early summer, although odd spikes continue to appear until well into the autumn. Even in the typical form there is much variation in the colour from light to dark blue, while the variety glaber rosea is a light rose. Glaucus, as its name implies, has foliage which is more or less glaucous, and stems 1ft. tall, while the flowers, produced in somewhat dense spikes are a bright violet purple. Heterophyllus forms a grand rock plant as it is so free in flowering and does so from July to September, a season when blossom is particularly welcome. The growth, 1½ft. high, is very neat, erect and bush-like, the flowers an attractive bright blue.

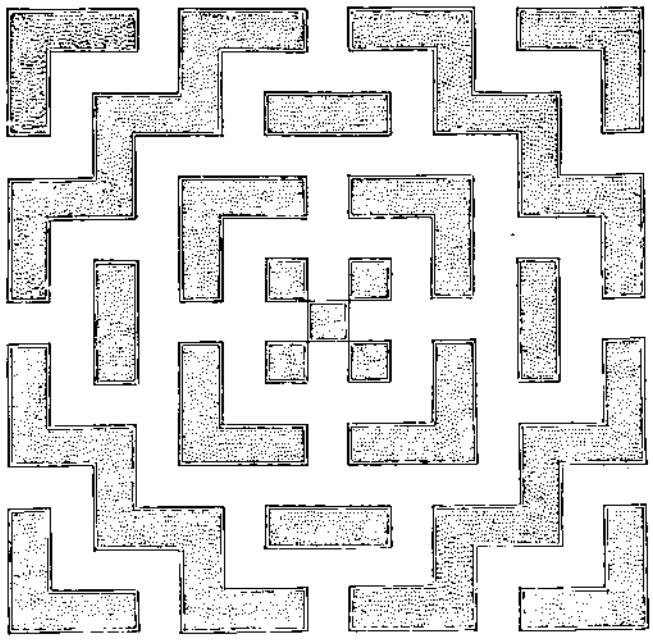
Lævigatus digitalis is splendid in the border, and flowers from June to August. These flowers are white, in loose spikes like foxgloves, and extremely decorative when cut. Ovatus, again, renders excellent service in the border, where, at a height of 2ft., it produces good spikes of true gentian blue flowers from July to September. Pubescens is one of the old-world garden favourites, rather dwarf and producing pale purple flowers in loose upright spikes. Isophyllis is one of the most striking September border plants, of light dainty growth and possessing brilliantly coloured flowers. The height is about 18ins. and the stem much branched and furnished with narrow green leaves. The flower spikes are abundant, with numbers of small bright coral-red tubular flowers that are extremely effective. Scouleri is fairly well known. The habit is that of a shrubby evergreen, that flowers in early summer in the form of pale lilac racemes. Speciosus is a remarkably showy blue species, reaching a stature of 1½ft., with very long spikes of flower.

Finally, let us mention Davidsoni, a splendid dwarf shrubby species that has been the subject of considerable controversy. Some contend that this should correctly be known as rupicola, but the former name has become so well established that it will probably continue to be known by this for many years to come. The habit is sub-shrubby, scarcely rising from the ground. The leaves are a glaucous grey and the flowers vivid ruby red.

H. W. CANNING-WRIGHT.

KNOT GARDENS

THE recent laying out of an Elizabethan knot garden at Hampton Court has aroused an interest which may result—and if so, so much the better—in the general revival of a quaint and pleasing horticultural fashion. Knot gardens, or parterres, as they were called in France and by some English gardeners, were introduced into England certainly as early as the reign of Henry VIII, but it was not until the time of Elizabeth that they touched the zenith of their vogue. Then every great house had at least one parterre, while, in some instances, the whole of the flower garden, no matter how large its area, was laid out in the formal little beds, arranged in designs varying in degrees of elaboration, but always within a rectangle and framed, as it were, with turfed "alleys" often "pleached" or roofed with branches of trees such as hornbeam, yew or box.



A DESIGN FOR A KNOT GARDEN IN JOHN REA'S "FLORA."

In the majority of these formal gardens the knots or "frets" were outlined with a low-growing shrub, such as box, kept severely clipped, but a live edging was by no means invariable. In Lord Paulet's garden at Hinton St. George, the "compartments" were marked out by brickwork, and John Rea, in his "Flora," the second edition of which was published in 1676, says that the beds in his ideal garden, which he picturesquely describes as "fashioned in the form of a Cabinet with several Boxes fit to receive and securely to hold Nature's choicest jewels," should be edged with "rails," 4ins. broad and 1½ins. thick, with a half-round top. These were to be dressed with linseed oil, red lead and umber before use. Rea advocates the use of this wooden framing because it is so quickly ready that the beds will be "presently in perfection," whereas French box,

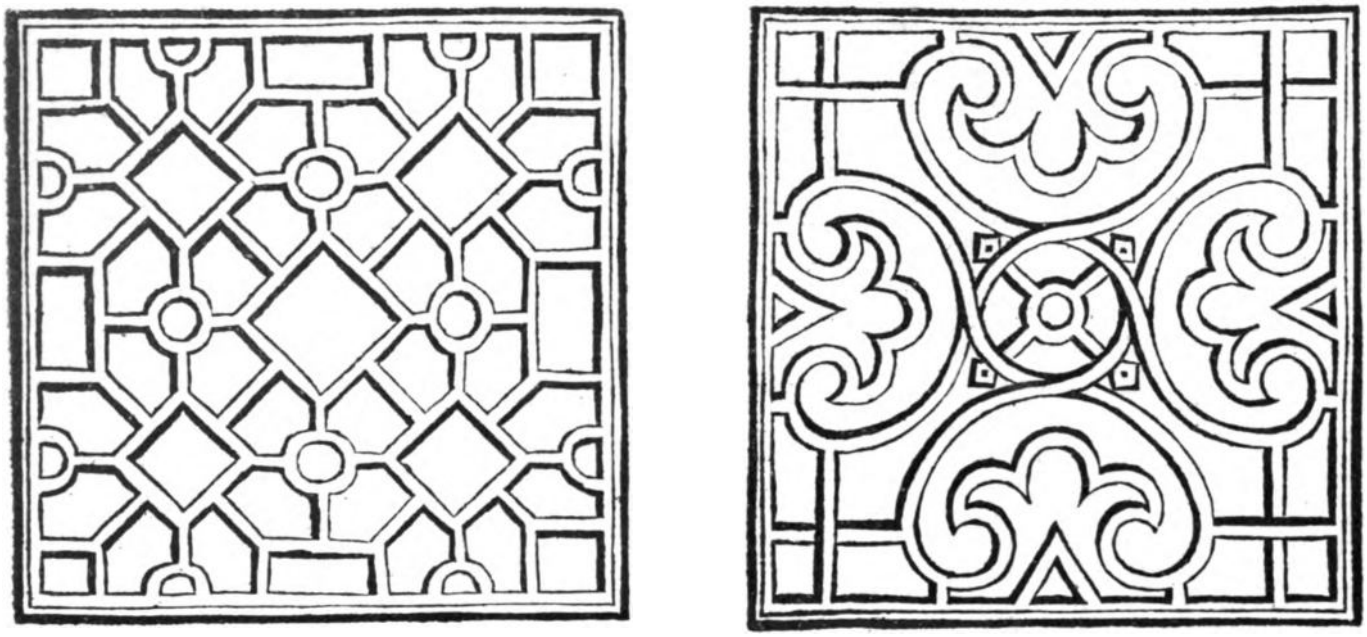
Digitized by Google

which he gives as an alternative "where timber is scarce," is slow-growing; moreover, it is necessary to cut the roots away on the inside with a keen spade every other year to stop them running into the bed, and to shear the top thrice yearly.

On the other hand, the author of the "Country House-wives Garden" (1660), prefers that the "frets" should be outlined with growing plants, of which he supplies rather a queer list. He omits box, but includes "Privit, Raisins, Fea-berries, Roses, Thornes, Issop, and Sage." What exactly were the raisins, one speculates, and likewise the fea-berries, which latter, by the way, appear as "fe-berries" in other seventeenth century gardening books? As to the planting of the knots themselves, the old-time gardeners dismiss the subject with an annoying vagueness. Rea tells us that tall flowers such as Crown Imperials and Martagon lilies should be placed at the corners of the beds and "tufts a Seventh of Cut-work of Grass and Imbroidery; an Eighth whose middle is all Cut-work and the Border Imbroidery; a Ninth, on the contrary, whose Borders are all Cut-work and the middle Imbroidery; and lastly, another sort whose middle is partly Imbroidery, partly Cut-work and green Turf, with Borders of Turf and Cut-work. *Note:* Imbroidery = those draughts which represent in effect those we have on our Cloaths and look like foliage, in Gard'ners' language called Branch-work. Below the Foliage certain Flowers called Flourishings."

The intricacies of these directions make one's brain reel in the effort to grasp the distinctions between the various styles, and the explanatory note does not provide much enlightenment.

Francis Bacon, in his famous essay "Of Gardens," writes, "As for the making of Knots or figures with divers coloured earths . . . they be but toys, you may see as good sights many a time in tarts." Coloured sands and earths, always



THE LOZENGE DESIGN FOR A KNOT GARDEN AND THE FRET, BOTH FROM THE "COUNTRY HOUSE-WIVES GARDEN."

of the best Pionies" in the centre of the principal ones, but for the fillings, bulbs and tubers, such as tulips, narcissi, hyacinths, ranunculus and irises, are alone mentioned, the meagre list concluding airily with "and all other kinds of good roots." In the surrounding borders, however, divided by green alleys from the knot garden proper, Rea says that double rose campion, double none-such wallflowers, double stock-gilliflowers, red primroses, hepaticas and dame's violets are to be planted.

In both the "Flora" and the "Country House-wives Garden," a number of plans of "frets" for knot gardens are illustrated, those in the latter volume under such names as Cinqfoile, Flower-de-Luce; Trefoyle, Crosse-bow and Maze. Some of them—especially the maze—are excessively elaborate and would call for the greatest nicety in cutting, but it is only when one reads the description of parterre designs as set forth in "The Retir'd Gardener," of Loudon and Wise, who were respectively gardeners to Charles II and Queen Anne, that it is possible to realise what a very serious business the planning of such a garden was. Quoth the gardener to the gentleman—the instructions are in dialogue form—"Some Parterres are said to be imbroider'd; others partly imbroider'd and partly Cut-work with Borders; a Third sort compos'd of Grass-work only; a Fourth made up of Imbroidery and Grass-work; a Fifth only Cut-work; a Sixth nothing but Cut-work and tufts of Grass; popular in French parterres, came to be used more freely in England, however, at a later date, in the gardens made under the Dutch influence after the accession of William and Mary. In these the knots or frets were on a smaller scale, and miniature canals, sometimes spanned by toy bridges, were often introduced. Glass balls and other meretricious ornaments were mingled with the flowers; a great error in taste it seems to us to-day, although it must be admitted that Bacon, rather inconsistently, it would seem, with his condemnation of coloured earths, commends the use of "plates of coloured glass, gilt, for the sun to play upon."

The popularity of the knot garden waned after the first quarter of the eighteenth century. Taste began then to veer towards the so-called "natural," or "romantic" style, the style of Kent, of Brown, of Mason and of Repton, of which expanses of turf, groups of trees and shrubs, curving paths and winding streams, Greek temples and long "vistas" were the essential features. Such gardens were pleasing, even beautiful, on a large scale, but when translated into miniature proportions they became dreary little combinations of patches of meaningless lawn, thickets of dingy evergreens, wriggling paths and absurd trickles of water. Yet gardens of this type, for no very obvious reason, continued in general favour in England until the nineteenth century was middle-aged and the "bedding-out" craze had begun to develop.

THE FORTNIGHTLY MEETING OF THE R.H.S.

THERE was a miscellaneous collection of plants at the Royal Horticultural Society's meeting on Tuesday, August 26th. The attendance was very poor owing, no doubt, to the fact that so many people are out of town on holiday at present. The exhibits were not so numerous as usual. Unfortunately, the Shrewsbury and Southport shows clashed more or less with this meeting. According to the book of arrangements it should have been a plum show. However, only one firm exhibited a collection of these fruits.

In the centre of the hall Messrs. George Bunyard and Co. had a large collection of pot-grown plum trees laden with luscious fruits. The specimens shown were exceedingly well grown. Here were such sorts as Victoria, Monarch, Giant Prune, Kirke's Blue, Late Orange, Coe's Golden Drop, Early Transparent Gage, Indian Blood and Archduke.

A wonderful collection of large-flowered decorative dahlias was shown by Messrs. J. Stredwick and Son. Of outstanding interest were Alice Amos, a large pure white flower; Sheila Ward, lemon yellow; Mabel Lawrence, scarlet; Kitty Rogers, rosy white. Nearly all the flowers shown were marked by the floral committee for trial at Wisley.

Messrs. Kelway and Son showed their well known "Langprim" hybrid gladioli. Here were such sorts as Langport Scarlet, Golden Girl, Painted Lady, D'Orsay, White Swan and Louis N. Parker.

The only other exhibit of gladioli was from Mr. Alfred Edwards. This was mainly an exhibit of primulinus hybrids. We noted such "prims" as La Saviere, an exceedingly attractive sort with apricot flowers with carmine blotches; Alice Tiplady, orange saffron. Among the large-flowered sorts were Baron J. Hulot, indigo blue; L'Immaculée, a very fine pure white.

Messrs. D. Prior and Son had an exhibit of roses containing good specimens of K. of K., Ophelia, Mrs. Henry Morse, Los Angeles and Independence Day. Messrs. Chaplin Brothers, the Rev. J. H. Pemberton and Messrs. Easlea and Son also showed roses.

A very representative collection of violas was staged by Mr. W. Yandell of Maidenhead. Conspicuous sorts were Geo. Macdonald, primrose; Edina, dark blue; Moseley Perfection, yellow; Oxhill Purple; Klondyke, yellow; Admiral Hood, cream, edged lavender.

Ornamental vines, Cratægus Pyracantha in fruit, fuchsias and clematises were shown by Messrs. L. R. Russell and Co.

A very interesting exhibit was staged by Mr. F. C. Stern of Goring-by-Sea. Here were several well flowered veronicas, such as VV. salicifolia, speciosa Pink Pearl and angustifolia. Other noteworthy plants were Kniphofia natalensis, Buddleia variabilis and Cotoneaster multiflora calocarpa.

Mr. G. A. Nix had a large exhibit of fruit, including black and white grapes, peaches, nectarines, plums, melons and pears. The fruits were very well grown. This exhibit was very tastefully arranged.

Large collections of herbaceous phloxes were shown by Messrs. J. Cheal and Sons and Messrs. Rich and Co.

Perpetual-flowering carnations were exhibited by Mr. C. Engelmann and Messrs. Allwood Brothers. The latter firm also showed numerous varieties of their famous Dianthus Allwoodii.

Messrs. Daniels Brothers showed their new September black currant, also several varieties of apples.

Perennial scabious were staged by Messrs. Isaac House and Sons.

Single bronze chrysanthemums were shown by Messrs. Scott and Wickham.

Hardy plants were exhibited by Mr. Hemsley of Crawley, Mr. G. Reuthe and Mr. F. G. Wood.

The Misses K. and E. Hopkins showed a miniature rock garden.

Seven dishes of well grown plums were staged by Mr. W. R. Scott of Nottingham.

THE BEAUTIFUL FLOWERS OF A HARDY HYBRID EUCRYPHIA, E. NYMANSAY.

SPRAYS OF DAVIDIA VILMORINIANA, WITH THEIR LONG, OVAL FRUITS.

NEW AND RARE PLANTS.

CLERODENDRON UGANDENSE.—A very beautiful greenhouse plant indigenous to East Africa. Large sprays of pendulous flowers were shown. The latter have pale bluish outer petals while the inner petals are dark blue. Award of merit. Shown by the Director, Royal Botanic Gardens, Kew.

COTONEASTER RUBENS.—Well fruited sprays of this prostrate shrub were shown. The berries are dark red. Award of merit. Shown by the Director, Royal Horticultural Society's Gardens, Wisley.

DAVIDIA VILMORINIANA.—Fruiting sprays of this deciduous tree were shown. The fruits are oval and about 1in. long. Native

Digitized by Google

of W. China. Shown by the Director, Royal Botanic Gardens, Kew.

EUONYMUS YEDOENSIS.—Sprays laden with magenta coloured fruits were shown. Award of merit. Shown by the Director, Royal Botanic Gardens, Kew.

GAULTHERIA PYROLOIDES.—This is a beautiful ericaceous shrub which bears pure white berries and thick, leathery leaves. The berries stand out in contrast to the foliage. Award of merit. Shown by the Director, R.H.S. Gardens, Wisley.

PYRUS AMERICANA NANA.—Large trusses bearing dark red fruits with a fine sheen were shown. Award of merit. Shown by the Director, Royal Botanic Gardens, Kew.

ROSA WEBBIANA.—This is a desirable Himalayan species which bears dull red hips. Shown by the Director, Royal Botanic Gardens, Kew.

EUCRYPHIA × NYMANSAY.—A beautiful plant somewhat in the way of E. cordifolia but flowers much larger. It is an interesting hybrid and said to be hardier than the other members of the family. Award of merit. Shown by Lieutenant-Colonel Messel.

EUONYMUS ALATUS F 392.—Fruiting sprays of this plant were shown. The fruits are much lighter in colour than E. yedoensis. Award of merit subject to correct naming. Shown by Mr. F. C. Stern.

SYRINGA JULIANA.—This plant is a native of W. China which has a violet-coloured calyx and the corolla deep lilac outside. It is fragrant. Award of merit. Shown by Mr. F. C. Stern.

SYRINGA POTANINII.—A well flowered specimen was shown. The flowers are powerfully fragrant and are of whitish colour. This plant should become exceedingly popular. Award of merit. Shown by Mr. F. C. Stern.

CATTLEYA TAGUS var. EXCELSIOR (Rhoda × King George).—A noteworthy advance in the production of the large-flowered yellow cattleya. This successful combination of four species has yielded a flower in which the stiff and broadly formed sepals and petals are rich canary yellow, the roundly shaped labellum velvety crimson, with gold venation in the throat. First-class certificate. Shown by Messrs. Flory and Black.

LÆLIO-CATTLEYA MRS. T. WARD var. MAJESTICA (L.-C. Hiawatha × L.-C. Lustre).—A large and finely built flower, somewhat flattish in shape, the broad segments bright purple, the labellum of deep crimson-purple extending to the extremity of the side lobes. Award of merit. Shown by Messrs. Cowan and Co.

LÆLIO-CATTLEYA PROFUSION var. COMPACTA (L.-C. Serbia × C. Hardyana).—The specific name of this hybrid well denotes the profusion of flowers produced on a batch of these plants. This example, an immature plant, bore a spike of three compactly formed blooms, of rose-purple colour, the roundish labellum of much darker tint and crisped at the margin. Award of merit. Shown by Messrs. J. and A. McBean.

A cultural commendation was awarded to Mr. Thurgood, orchid grower to Mr. H. T. Pitt, Stamford Hill, N., for a finely cultivated plant of Maxillaria venusta, bearing nine flowers, white, with buff-yellow on the labellum. This species is a native of Columbia.

FLOWERS SEEN AT SHREWSBURY

VISITORS to the old-world town of Shrewsbury for the occasion of the Floral Fête obtain many fresh impressions, especially those there for the first time. One of them to visitors from the South is that summer is still in its heyday, for one sees flowers sent from the North which are just coming to their best with their later season.

This show, of course, is one of the largest in the country, being, in point of size, only second to Chelsea. In the number of visitors it easily eclipses the latter, but there are other attractions which add to those of the fruit show.

Among the features of this fête are the keen competitions which enhance the interest of the show, for competitions bring out points and create enthusiasm not found in an entirely non-competitive show.

The occasion of the jubilee celebration of the Shropshire Horticultural Society was one of the finest shows they have ever held.

Quite the best lot ever seen of crotons (a complete avenue of them) came from the well known growers who compete in the large group classes and were staged by Messrs. Cypher, Cheltenham; Mr. Holmes, Chesterfield; Mr. McDonald, gardener to Sir Geo. Kenrick; and Mr. Manning, Dudley. The old varieties are still the best, such as Warrenii and Prince of Wales. These groups included choice cattleyas and dainty oncidiums, with other orchids. A light effect was further obtained with the use of Humea elegans, Aralia Veitchii, and such plants. There was never any attempt at massing, which is fatal to the lightly arranged group.

Probably the finest group in the show was of vegetables, staged by the veteran, Mr. E. Beckett, who, if possible, eclipsed his former triumphs and called for special recognition by the judges. Among interesting subjects being the aubergine, which so attracted the attention of H.M. the King at Chelsea Show. A pea which is eaten in the pod when young, the delicious International, was there, as well as Carter's Quite Content, and several others. All vegetables in season were represented in perfect specimens.

The group of plants from Messrs. John Peed and Sons composed of caladiums, streptocarpus, etc., contained a noble specimen of the Dracæna Victoria some 6ft. high.

Fine groups of vegetables, fruit and flowers from Messrs. Webb and Sons, Messrs. Dickson and Robinson, and Messrs. Toogood and Sons well sustained their reputations.

FRUITS.

Fruits are always one of the outstanding features of Shrewsbury Show, and the class known as The Champion Decorated Table is always a source of education. The Duke of Northumberland's gardener, Mr. Barker, secured first prize and challenge cup for his arrangement of Peaches, Dymond, Peregrine and Royal George; Nectarines, Dryden and Lord Napier; Plum Jefferson; Apples, Ribston and Cox's Orange Pippin; Fig Brown Turkey; Melons; Grapes, Muscat Hamburgh and Muscat of Alexandra. The second prize went to Lord Belper's gardener, Mr. J. McCartney, who also had, additional to the above, Nectarine River's Orange, a very choice variety; Apricot Moor Park; Pear Souv. du Congrès; Apples, Peasgood's Nonsuch and Wealthy.

In the class for twelve bunches of grapes, the first prize fell to Mr. Owen, gardener to the Pyll-y-Crochan Hotel Co. His six varieties being Madresfield Court, Muscat of Alexandra, Mrs. Prince's Muscat (black), Alicante and Black Hamburgh. The Duke of Newcastle (gardener, Mr. S. Barker), was second, Messrs. Webber and Sons, Minehead, third. In the latter were some magnificent Appley Towers, one of the most handsome of black grapes. Messrs. Webber were also winners in the class for twelve dishes of fruit, consisting of Apple Beauty of Bath, Nectarine Darwin, Peaches, Early Crawford and Dr. Hogg, Cherry Morello, Plum Belle de Louvain, currants, grapes, etc.

There were several other classes for plates of peaches, nectarines, apricots, apples, pears, plums, etc.

Magnificently fruited apples on pot-grown trees came from The Kings Acre Nurseries, Limited. Herring's Pippin, a little known variety, was one of their finest for quality and appearance combined.

The very late black currant, "Daniel's September," was exhibited by Messrs. Daniels Bros.

Plum Purple Pershore was well shown by Mr. E. J. Parsons, Worcester, who also had good fruits of Plum Belle de Louvain, the largest cooking plum at this season.

ROSES.

Golden Emblem is now probably the most popular yellow rose, and was shown in nearly every group. Mrs. H. Morse the most popular carmine pink; Queen Alexandra, gorgeous red with old gold reverse; Betty Uprichard, salmon carmine, and Lady Inchiquin, orange vermilion, were all exceptionally brilliant. The winners of the competitive classes being Messrs. Gunn and Son (Olton), Thos. Robinson (Nottingham), Messrs. Bees (Liverpool), and Messrs. Dunton (Wolverhampton). A new rose which came to the fore on this occasion being W. F. Dreer, a relative of the lovely Los Angeles. The former is orange or golden yellow shaded with peach pink.

HERBACEOUS PLANTS.

At a date when summer and autumn meet, the hardy flowers are very varied. The Kniphofia aloides in the winning group of Messrs. Gunn and Son, and the Yucca filimentosa in that of Messrs. Bees, Limited, were two fine things to make a note of. Phloxes and pyrethrums were prominent in the exhibit from Mr. Maurice Prichard.

From Messrs. Bakers, Codsall, came a perfect piece of landscape work with drooping trees over running water. Mr. Clarence Elliott specialised in conifers for rock gardens. A great variety of phloxes from Scotland was in the group of Mr. John Forbes of Hawick. Dahlias from Mr. Woolman and Mr. H. Clarke, Taunton, included Nancy, rosy salmon, and Triton, dark scarlet, also in a magnificent lot seat by Messrs. Dobbie and Co.

Sweet peas were less extensively shown than usual. The winning group coming from Mr. A. S. Dunton, while Mr. Robert Bolton had a magnificent lot in his non-competitive group.

The art of the florist has scope at this show, and some wonderful designs in cut flowers were seen.

CARNATIONS.

All the year round this flower is seen at the shows, but at this date it is not at its best, yet Laddie, in the huge display by Mr. C. Engelmann, and Eileen Low, in Messrs. Stuart Low and Co.'s group, were still in fine form. Border carnations were well displayed by Messrs. Jones Bros., Shrewsbury, but several of the usual exhibitors were missing.

The Shropshire Horticultural Society sets a laudable example in the amount of prize money offered to gardeners, which might well be emulated in other directions. There were no fewer than 171 classes in their schedule, and the foregoing is but an abbreviated survey. Many awards were given in the non-competitive section.

CORRESPONDENCE

RHUS COTINUS.

SIR,—I was much interested by seeing in your issue of August 16th an illustration of a specimen of Rhus Cotinus as grown by Mr. Cooper of Lindfield, Sussex. But I would venture to suggest that anyone thinking of growing it should train it as a bush, not as a standard, as in Mr. Cooper's picture. I enclose you a photograph [see frontispiece] of one I have in my garden. It is 21ft. wide, 11ft. high and 14ft. through. This is as fine a specimen of Rhus Cotinus as I have ever seen, and this year it has been wonderful, covered all over, as Mr. Cooper describes, with "magnificent filigree red web." The plant is twenty-five years of age.—J. W. READING.

WILD PLANTS IN THE ROCK GARDEN.

SIR,—Being a very amateurish gardener, I rather hesitate to write you. My excuse is a small rockery I made, which seems to interest most of my friends more than any other part of the garden and cost nothing, as I have filled it with wild plants from a bit of the coast on the east of Luce Bay. The flowers on the cliffs and heuchs are so lovely that I thought I would try to concentrate them, and the result has been better than I expected. The first to flower is scurvy-grass (Cochlearia officinalis), followed by meadow saxifrage (Saxifraga granulata) and the spring squill (Scilla verna). Then I have a few cushions of sea-thrift, bird's foot trefoil, lady's fingers, yellow rock roses and wild violets. Later on come the Burnet rose, Genista tinctoria, Geranium sanguineum, hawk-weed, sea-holly, horned-poppy, ladies' bedstraw, three St. John's worts (Hypericum perforatum, pulchrum and humifusum), purple and white thyme, a pinkish white and a yellow sedum, Scotch lovage, etc. I have also put in the white and common heather and bell heather, but they do not make a show yet, as they are still very small. I have found the easiest way to get all these plants to grow is to lift them in their seedling state in spring, but some, such as the Portland spurge, I have had great difficulty with. Up to now I have collected over fifty varieties and found it very interesting, but not too easy to recognise as seedlings. There is a wall behind the rockery covered with ivy, on the roots of which I have got Orobanche minor to grow. It is not pretty, but rather curious.—FRANK B. HOPKINS.

SAXIFRAGA CÆSIA.

SIR,—He is a rash man who would attempt to name a small critical saxifrage from even a good photograph reproduced in THE GARDEN. But I cannot see with my friend, M. Correvon, that Dr. Wacher's picture (page 537) represents either S. cochlearis minor (= S. Probyni Correv.), or "perhaps S. valdensis"; and if it is not Farrer's major form of cæsia, as suggested by Mr. Todd, it is more likely to be S. cæsia × Aizoon (= S. Burnati), a natural hybrid mentioned by Irving and Malby in their excellent book on saxifrages. In this beautifully illustrated work is a good photograph of S. cochlearis minor growing near the typical plant, as I have seen it in its full glory in the Maritime Alps. But, as M. Correvon knows well, all forms of cochlearis have a denser, longer and less erect panicle than the small upright corymbs of the few flowers in Dr. Wacher's photograph.

Burnat says ("Flore des Alpes Marit.," Vol. III, page 271), that S. valdensis recorded by G. Maw (in *Gardeners' Chronicle*, 1874), from rocks near Tenda and growing with S. cochlearis, was probably the result of confusion with S. cæsia or S. diapensoides; and he points out that though valdensis is very closely allied to the two last, its habit is very restricted—"très restreinte." Much useful and exact information about these and other saxifrages will be found in the late M. Burnat's great, but still unfinished, work.

It is well known to every field botanist who has travelled in the Alps that S. Aizoon is extremely polymorphic and often very small in its leaves, rosettes and stature. Moreover, it hybridises rather freely. The leaves of all these species when normal can easily be distinguished by the aid of a good descriptive "Flora." And of their stems those of cæsia are the least glandular, and often they are glabrous below; so this helps us to understand how Dr. Wacher's plant "may be identified by the pubescence or smoothness of the stems," though it is merely a rough guide.

To the free and abridged translation of Grenier and Godron's description of S. valdensis we may add that they say it is a species "remarkable for the characters which it seems to borrow from all the neighbouring (*i.e.*, allied) species, though it is with S. cæsia that it has the closest affinity."—H. S. THOMPSON, *Clifton*.

THE LIZARD ORCHIS.

SIR,—I enclose a photograph of the Lizard orchis (Orchis hircina) which I found in

ORCHIS HIRCINA IN KENT.

June in the neighbourhood of Sandwich. The flower came out in water and it was interesting to watch the long central segment of the lip unfolding. The smell is decidedly unpleasant. This is the fourth specimen which I have seen or known of in Kent, but the plant is very uncommon in England.—C. G. FIELD-MARSHAM.

ORNITHOGALUM THYRSOIDES.

SIR,—Your correspondent Mr. Jacob asks in the issue of THE GARDEN (August 23rd, 1924) for further information about Ornithogalum thyrsoides. A bunch of the cut flowers was on view under this name at one of the fortnightly shows at Vincent Square early in the year. They are regularly shipped from South Africa, but are not generally or widely sold in the London shops. A friend in South Africa sent me some bulbs a few months ago. In South Africa they are known as "chinkerichees" (or, alternatively, as snowdrops, to which flower they have but a faint resemblance, since they grow in corymbs and are not tinged with green). Mr. Jacob is, I think, misinformed as to the flower having any dark markings or centres. The flower shown at Vincent Square had a pinkish fawn tinge outside and a pure white inside. Messrs. Barr's representative told me that they had so far failed to flower them, but no doubt he has done so by now, as I have three spikes showing bloom. I have tried two methods of culture—indoors in a cool house and out of doors. Besides giving much drainage, I have planted them extra firmly with a compost mainly of sand and giving very little water, so as to imitate their natural circumstances on the veldt. If these spikes should open well, I will probably send them up to Vincent Square to be seen. Specimens were on view for a time at Wembley in the South African Pavilion.—E. H. C.

MAGENTA.

SIR,—If your correspondent "M. H. W." has not already received an ample reply to the enquiry for magenta-coloured flowers, there are one or two that I might suggest. A fine vivid magenta may be found among the new hybrid eschscholtzias of the erecta type and also among the deep coloured forms of Colchicum speciosum. The magenta eschscholtzia combines well either with the pale buff yellows or with the mauves and purples that occur in the same group. The colchicum shows off its beauty of line best, I think, with no other companion than Cotula squalida or some loose-growing sedum, unless it be its own magnificent white variety. It does not associate very well with the ordinary pink form. Rubus odoratus has made a pleasant group here with the dull yellow of Digitalis ambigua. It seems rather a pity that this fine flowering raspberry is seldom seen nowadays, for there are not many shrubs that bloom as freely in partial shade, and the flowers, perhaps rather too dull in tone to be classed as pure magenta, harmonise interestingly with the crimson fur of the new stems and the pale biscuit colour of the old ones that have shed their bark. Agrostemma coronaria in its dark form might be taken, perhaps, as a standard magenta, but I suspect that it is the grey-leafed plant mentioned by "M. H. W." It would have been included in the original note on magenta had its proper name not slipped away beyond recall, and I feared that it might not be generally recognised under its more intimate one of Bloody William. It is a favourite cottage garden plant in this part of the world (Buckinghamshire) and should be very useful in any colour scheme that includes magenta.—F. A. HAMPTON.

JASMINUM OFFICINALE.

SIR,—Among summer climbers none bears a more fragrant flower than the white jasmine, its scent being delicious. This being so, and remembering it is an old, well known plant, is it not remarkable how seldom, comparatively speaking, one is greeted by its presence and sweetness in a garden? Since living in this district I have seen a fair number of gardens, large and small, but in one other only than this have I seen a specimen. That such an omission is a great loss every lover of good garden plants will agree, for this jasmine is so hardy, so easy to grow, and beautiful alike in leafage and blossom. Being white, it is not an ideal flower for the white dining-cloth—I mean, to show up well—but it is quite effective on a coloured centre, if such can be arranged. The plant here is growing on the north-west side of the writer's house, and is now, the second week in August, full of blossom. Like the white tobacco plant, Nicotiana affinis, the white jasmine smells most sweet in the cool of the evening. It is easily propagated by layers and cuttings.—C. T., *Ampthill Park*.

NOTES FROM CONTRIBUTORS

WHAT DID PERSEPHONE GATHER ON THE PLAIN OF ENNA?

I HAVE never been in Sicily except in the train on the way to Malta, so I am writing this query in the hope that someone who knows the island and its flora will make a sort of *ex cathedra* pronouncement as to whether the naughty young woman was going after a daffodil or an iris (?) when she got caught by Pluto and taken to Hades, to the inexpressible grief of her mother, Demeter.

"My life immortal though it be,
Is nought, she cries, for want of thee,
Persephone—Persephone."

Jean Ingelow's account of the episode is as follows:

"The daffodils were fair to see,
They nodded lightly on the lea,
Persephone—Persephone."

"Lo! one she marked of rarer growth
Than orchis or anemone,
For it the maiden left them both
And parted from her company.
Drawn nigh she deemed it fairer still
And stooped to gather by the rill
The daffodil, the daffodil."

Our Laureate's (Robert Bridges) account is different. He, too, pictures Demeter filled with a great sorrow:

"Saw ye the mighty Mother, where she went
Searching the land?
Nor night nor day resting from her lament,
With smoky torch in hand."

But thus speaks Persephone:

"Coud I but find
[Bridges always writes "coud" for "could." —J. J.]
A scented Iris I should be content:
Yet men would call me proud: Iris is Pride."

(From "Demeter, A Mask," 1905.)

The "King of Hell" consulted Zeus:

"Said I, my heart is set:
I take Demeter's child Persephone;
Dost thou consent? Whereto he gave his nod.
And I am come to-day with hidden powers
E'en unto Enna's fair Sicilian field,
To rob her from the earth."

Which flower was it that made this possible?
—JOSEPH JACOB.

CLEMATIS RECTA.

OLD though it is in gardens, Clematis recta, erroneously called C. erecta, is not too well known, although it is an excellent plant for the herbaceous border and might be utilised successfully in the wild garden. It is one of the non-climbing species; but when it grows tall, as it will do in rich soil, it shows some sign of desiring to adopt the habits of its scandent sisters by a twisting of the growths. In most cases, also, it requires to be staked to prevent it from trailing over the ground. This feature suggests, also, its employment for hanging over rocks in the rock garden or for growing on steep banks, which it might veil with its foliage and creamy white flowers.

Individually, the flowers are small, but they are borne in great numbers together and present what is truly a pleasing mass of soft white bloom. There are several recognised forms, but these are difficult to identify and distinguish in the case of the single varieties. That called C. recta mandschurica is considered one of the best, but it is impossible to be certain of acquiring the true form, and the reader will be well advised to try to see the plants in bloom and select what he prefers. The writer once grew a good batch of seedlings of C. recta from purchased seeds, and there was a considerable difference among them in the size of flower and in growth. Probably a prolonged course of seedling raising and selection would yield a good result in the improvement of the flowers, and the hybridiser who took the flower in hand along with other species would probably achieve some valuable plants.

This clematis varies greatly in stature, and I have seen it up to quite 4ft. in height; but about 3ft. seems to be an average stature. I have at present a small plant which is not more than 18ins. high. The foliage is characteristic of the clematises in its general appearance and the stems are surmounted by heads of flower of considerable size. The blooms, as already mentioned, are of a pleasing shade of creamy white and a mass on a large plant is really beautiful. The flowers are also useful for cutting. There is a double variety, C. r. plena, which has been in cultivation for many years but is still scarce. C. recta may be raised from seeds quite easily, by sowing these under glass in spring and treating the seedlings in the same way as other hardy perennials. The plant makes a hard root-stock, rather difficult to divide, although it can be done with care. Some propagate it by means of cuttings also, and division or cuttings must be adopted for the propagation of the double variety. While Clematis recta cannot be recommended as showy, it is a pleasing plant of considerable merit.—S. ARNOTT.

PHYSOSTEGIA VIRGINIANA.

A DULL wet season is not altogether ideal for a herbaceous border, but the above plant, known also as Dracocephalum virginianum, has been most effective during the month of August. The flowers produced in terminal racemes are flesh coloured with a slight tinge of purple, each flower being almost an inch long. The erect herbaceous stems this year are 4ft. high, but during a drier season they are often a foot less in height. No doubt it would be an excellent plant for a damp situation. It is a native of North America, and was introduced during the sixteenth century.—T. W. B.

TWO RECIPES.

AUBERGINES A LA MAIORESE.

Slice the aubergines, pile the slices on a flat surface, sprinkling salt between the layers, place a weight of 12lb. to 15lb. on top to express the juice. After about an hour, remove weight and wipe each slice with a cloth, dust over with flour and fry in *lard*. Take the fried slices and arrange them in a fireproof dish in layers, sprinkling grated cheese (preferably Parmesan) and chopped citron peel and a spoonful of tomato sauce (to which has been added some butter) between each layer, until the dish is full, ending with a smooth covering of tomato sauce. Heat thoroughly in oven and serve in the fireproof dish.

GREEN PEA-POD SOUP.

Take the green pea-pods when the peas have been shelled and boil in a little water with a pinch of bi-carbonate of soda and some salt. When softened, rub through a *hair* sieve. Have some béchamel sauce ready, mix with the green paste of the pea-pods *very evenly*, adding enough cold milk to make the soup, which must be of a creamy texture and consistency. Bring to the boil and serve with little *croûtons* of bread fried a golden brown in *lard*.—A. BULWER.

MARKET GARDENS AND COMPENSATION FOR IMPROVEMENTS

THE NEW ACT.

THE Agricultural Holdings Act, 1923, affects to a considerable degree the interests of market gardeners and those engaged in fruit growing. The wording of the new Act, in certain sections, follows, to a large extent, and in some instances literally, the sections of the lately repealed Agricultural Holdings Act, 1908. It was in relation to such an instance that a case of importance to the occupiers of market gardens and to those concerned in fruit growing came recently before the Court of Appeal.

FUTURE AUTHORITY.

Where the sections in the old or in the new Acts apply, as therein provided, then it is enacted by both Acts that when agreed in writing that "the holding shall be let or treated as a market garden" the tenant shall be entitled to the benefit of the provisions mentioned for improvements. This raised the issue before the Court of Appeal in the case in point.

The Court gave its decision, in fact, after the new Act was passed, and as the relevant sections of both Acts are identical in this particular instance, the judgment of the Court will have binding force and authority in the future.

THE FACTS IN THE CASE.

A market gardener was a yearly tenant at a stated rental, and agreed to pay a further rent of 6 per cent. per annum on money expended by his landlord in supplying fruit trees. Clause 11 of his agreement stipulated that nothing contained in it should be deemed to be an agreement that any part of the premises should be let or leased as a market garden, or ground a claim for compensation. Notice to quit being given by the landlord, the tenant, however, claimed compensation on the basis that the holding was, in fact, a market garden. This was, indeed, the case, for a previous tenant had cultivated it as a market garden and, with the landlord's knowledge, the holding had been taken over and continued in cultivation as such.

DECISION OF THE COURT OF APPEAL.

The Court of Appeal held that the word "treated" in the Act did not there mean simply that the holding should be in use or cultivation as a market garden, but that it should be let and occupied as such, and, further, that Clause 11 in the written agreement had to be given its proper legal effect. The Court also held that an agreement in writing that the holding should be let or treated as a market garden was a condition precedent to such a claim, and laid it down that if a tenant had a right to claim compensation he could not contract himself out of it, but that no such right arose here, because the condition precedent had never been satisfied.

A NECESSARY PRECAUTION.

Prospective and other tenants will recognise from this case that it is not sufficient merely for premises to be used or cultivated as market gardens, but that if they desire to secure the benefit of the special statutory provisions for market gardens they must be particularly careful to see that their tenancy agreements expressly stipulate that their premises, or the required part, are also let or treated thereunder as market gardens.

It may be added that Section 49 of the new Act makes further provision as to market gardens of far-reaching importance to occupying tenants.—A LAWYER.

SIMPLE GARDENING

AZALEAS.

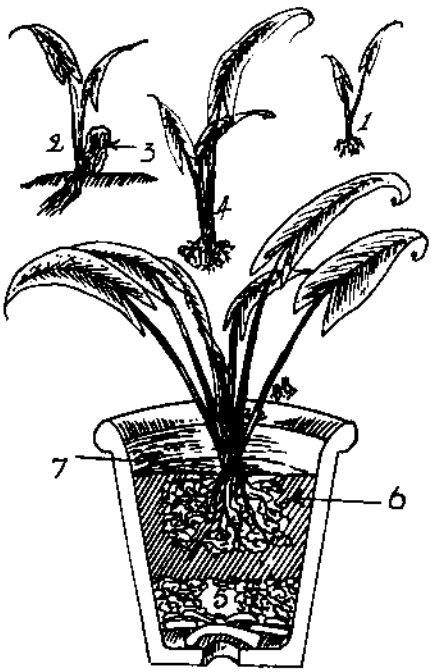
THESE plants are not so difficult to manage as many amateur cultivators suppose. They are general favourites and make a brave show in the greenhouse or conservatory during the late winter and early spring months. From the end of June to the present time the plants thrive best in the open air in a cool position, such as a bed of ashes on the north side of a wall or fence. The plants make the current year's growth in such positions, but on no account should they be neglected as regards watering and syringing. It is during this growing period that a little feeding may be done with benefit to the plants. The last application of any kind of stimulant shou'd be given not later than the end of August. From this date to the end of the flowering stage, clear water only should be applied. If manure water and artificials of a stimulating character be given before the flower buds open, the latter will, probably, turn brown and fall off. These flower-buds have, in themselves and in the leaves and stems, sufficient nutriment stored up to enable the resultant flowers to fully develop. The roots of the plants are fine and fibrous, and are easily killed by over-dryness, over-watering and strong stimulants. The foliage of Indian azaleas is very precious and should be preserved from the attacks of red spider and thrips —two great pests of the plants. Consistent syringing should be the rule after the plants are placed under glass this month till the middle of December, and cool treatment generally is beneficial.

HERBS.

It is a pity that the herb border is not more carefully attended to than is, unfortunately, the case generally. There are isolated cases where herbs are well grown, well harvested and well stored. There is a big demand for herbs in the kitchen; this requirement is continuous, and for this reason it is very important that preparations be made now to meet it. Perhaps any deficiency may be noted now so that the necessary seeds may be sown next spring and roots and cuttings inserted in due season. A small bed will supply the demands of a medium-sized establishment. In every garden should be grown parsley, sage, thyme, mint in fair quantities. In smaller quantities basil, chives, sweet marjoram, summer and winter savory, tarragon and fennel. Mint likes a moist but well drained soil to grow in, but nearly all the others thrive in a lighter rooting medium and in a very sunny position. The soil should not be made very rich, only moderately so. It should be the aim of the cultivator to produce a medium-strength plant and in most cases free-flowering. At the latter stage herbs should be cut and dried for storing. The present is a good time to store in small bunches in a cool, dry shed or room free from cobwebs and dust. Above all the suspended bunches place sheets of paper to prevent dust lodging on them.

LIFTING AND POTTING ARUM LILIES.

There are many cultivators who plant out their arum lilies in early summer and lift and repot them in early autumn. Where this system obtains the present is a suitable time to carry out the work of repotting. Of course, the pots should



be washed clean and dried, a good compost of loam and rotted manure prepared, and clean potsherds for drainage. Probably young side plants will have grown on the older specimens. These shown at Nos. 1, 2 and 4, should be carefully detached and potted singly in small pots. Where old plants were not "dressed" prior to their planting some hard basal stem-tubers will be found as shown at No. 3. These should be removed so that the young side plant, No. 2, can be potted properly. Sound drainage is shown at No. 5 for the large specimens; No. 6, the new compost; No. 7, space for water and surface dressing. For several weeks after potting keep the plants on the north side of a wall, safe from frosts, before placing them in the greenhouse.

PREPARING FRAMES FOR WINTER USE.

Garden frames are always interesting and, when properly managed, very remunerative structures. I have always been interested in them since I was a boy of ten, when an uncle gave me a frame light, unglazed, and I insisted upon carrying it to my home—four miles away. There I built the sides and glazed the light, and have not forgotten the crops of cucumbers grown in it in summer, nor the calceolarias in winter, radishes and early lettuce in spring. In these days the enthusiast can store away hundreds of precious plants and cuttings in the garden frame, where they will be safe from inclement weather. There are alpines, herbaceous plants, choice shrubs, seedlings and cuttings. But the frame should be made weather-proof now; it is too late when the plants are inside, and the fogs, frosts and rains of winter have come. The sides of a garden frame are best preserved by placing them on a single row of bricks. The latter absorb moisture and so there is not any danger of the wood rotting. Even one coat of good paint will keep out moisture during the winter; of course, I am referring to old frames, not new ones. Then, if any repairs are needed, do them now. The internal arrangements should depend upon the kind of plant to be wintered. In a deep frame some shelves will be an advantage for dwarf plants, but in every case ashes form a good base, especially for sweet peas in pots and boxes. Composts for beds in frames should be prepared, too. Soil bases should be watered with a strong solution of lime water to get rid of slugs and earthworms.

SOWING SWEET PEAS IN POTS.

Early-raised plants always flower more freely and bear finer blooms than those raised at a late date. The cultivator should make out his list of seeds required, at once. Some seeds may need chipping before they are sown, this fact is generally intimated on the seed packet. Many seeds look like rubbish and certainly not worth sowing. Do not be influenced by the poor appearance of the seeds. There are two ways—both good—of sowing the seeds; first, in small pots, duly re-potting the resultant plants into larger ones or planting them out undisturbed; second, many seeds in large pots. In the latter case 9in. pots should be selected, washed and dried. A fairly rich compost should be passed through a half-inch-mesh sieve. The compost in the pots should be watered prior to sowing the seeds. Scatter dry lime in the frame before placing the seed pots in it, to guard against slugs. Early in the new year turn out the young plants—the soil, owing to the sifting, will fall clear of the roots—and re-pot them singly in small pots. In due course these plants may be planted out or transferred to large pots and flowered in the latter.

GEORGE GARNER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Cabbage.—During the next few weeks, and directly the plants are large enough, a good batch of this indispensable vegetable must be planted out. Regarding the site there is no better spot than an onion bed from which the crop has been lifted. There is no need to dig the plot, but it should receive a hoeing, and all weeds must be removed. Set out the plants in lines 18ins. apart and allow a space of 1ft. in the lines. If necessary, afford each plant a thorough watering and at intervals use the hoe to keep down seedling weeds and open the soil.

Potatoes.—All crops that are ready may be lifted and, providing the tubers are fully developed, there is no need to wait till the haulm has died down. By leaving them in the soil for a longer period than is necessary is only courting disaster, especially in a dull wet season such as we have experienced this year.

Parsley.—Where this is always in demand, and a supply is essential during the winter months, a few plants should be lifted and set in a cold frame. In such a position they are easily protected through a period of severe weather.

THE HARDY FRUIT GARDEN.

Gathering Fruit.—This is no doubt the most important work at the present time in many gardens, and I strongly advise that such a task ought to be carried out with extreme care, particularly with soft-skinned apples such as Stirling Castle, etc. The pear crop should be extended over as long a period as possible, and, with varieties like Williams, a few may be gathered at intervals, and if these are placed in a room or warm greenhouse they will ripen very quickly. All fruit in store must be placed on a wooden staging or in boxes and not on straw, because the flavour will be spoilt.

Bush Fruits.—Although it is early for planting, it is not too early to prepare for new plantations of bush fruits. Having selected the site, the plot should be trenched or dug two spits deep, and if the soil is poor, add a liberal dressing of manure. By doing this work now the soil will be ready for planting directly the leaves fall, and, providing the bushes are available, this is no doubt the best time for planting.

THE FLOWER GARDEN.

Violets.—It is time these were lifted and placed in their flowering quarters, viz., cold frames. Any good soil will suit them, but it should be rather on the light side, and when the operation is completed the leaves should be within a few inches of the glass. Lift the plants with a ball of soil and set them out so that the leaves just touch, making the soil firm about the roots, afterwards affording a liberal quantity of water. For the time being admit plenty of air, and all decayed leaves must be picked off as they appear.

Violas.—Now is the time to propagate these charming flowers, and they will readily form roots if cuttings are placed in borders or nursery beds which are not fully exposed to the sun. A liberal sprinkling of sand is essential, and young growths about 3ins. long taken from the base of the old plants will make useful cuttings. Where they are liable to decay during the winter months when given an open border, a skeleton frame containing a layer of sandy soil will be a success, especially if a light can be placed over them when the weather is very wet.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Broad Beans.—As soon as the plants are finished bearing, they should be cleared from the ground. The old stems and any other spent material should be collected and burned.

Cardoons. — Notwithstanding the wet weather, have made good progress, and the most forward plants should have the stems—if not already done—slightly tied with matting, then the earth or other blanching material placed around them. Later batches should have the same attention when sufficiently grown.

Peas.—Late peas, like early varieties sometimes suffer by having pods torn and the peas taken out by some members of the feathered community. It behoves each one therefore to keep a sharp look-out on lines of peas, and stretch nets over them should any of the pods appear damaged.

THE FLOWER GARDEN.

Calceolarias.—There is no doubt that the old yellow bedding calceolaria is a good stand-by, its vivid shade for present-day colour schemes is perhaps a little glaring. The paler lemon-coloured variety is more to be desired. There is also a fine bronzy-brown kind with a sturdy and neat habit, which is really a gem, and, despite the continued wet weather, these brown calceolarias have kept up a good show, although with less rain they would certainly have been more beautiful. The wet, however, has favoured growth and there are plenty of good healthy shoots for cuttings. The cuttings should be secured now and inserted 3ins. apart in firm, sandy soil in a cold frame. Keep the frame lights closed and the cuttings shaded from bright sunshine for a fortnight or so. After this period allow a little air, gradually increasing the amount until the frame lights can be pulled off on all fine days. Thus the plants will be kept dwarf and hardy.

Herbaceous Borders.—If hardy plant borders are to be overhauled, now is a good time to make a start with the work. All plants of the same species or variety, when dug up, should be collected, then temporarily placed close together in lines on a section of vacant ground as near the border, or borders, as possible. Each line or section of plants of the same kind in the line should be properly labelled indicating height and colour where necessary and the number of plants in each group. Plants infested with perennial weeds should either be cleaned directly they are dug up or thrown away. When all the plants have been cleared from the ground the border or borders should be thoroughly forked over; this will level the ground and provide an opportunity to get out underground stems of perennial weeds and portions of plant roots which may have been left. If the ground is impoverished, plenty of decayed farmyard manure and leaf-mould should be placed on the border and well incorporated with the soil as the trenching proceeds. As soon as the trenching is completed the surface soil should be raked and the stations marked off; then the plants should be replanted in whatever formation it is intended to place them.

Pinks.—Cuttings inserted in July should now be well rooted, and if the frame or frames in which they are growing are needed, the young plants should be set out in beds, or they may be run out in lines on some of the borders and transplanted in permanent places in the spring.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Achimenes as they pass out of flower may be stood in cold frames, where the lights can be kept over them, gradually withholding water at the root as they show signs of dying down. During the winter they should be stored in a warm, dry shed or greenhouse. They may either be left in the pots or pans, or may be turned out and stored in dry sand for the winter.

Hippeastrums as they finish their growth and die down may be removed to cold frames, where the lights can be kept over them, otherwise they should be fully exposed to the sun. During the winter they must be stored in a dry building where the temperature does not fall below 45°. It is unwise to store them underneath stages unless they can be kept dry. Before putting them away they should be carefully examined for mealy bug. The plants that finish their growth and are dried off first should be kept separate, as they should be used for the earlier batches; they naturally respond better than plants that have finished their growth later.

Antirrhinums in their many beautiful varieties are very useful for the conservatory and greenhouse during the spring. The intermediate varieties are most suitable for pot culture, as under glass they grow taller than what they do outdoors. For pot work they should be sown in cold frames at this time. When large enough to handle, the seedlings may be pricked off into boxes. Afterwards, when large enough, they may be potted off singly into small 60-sized pots, or three or four plants can be placed round the edge of 48-sized pots. Grown singly, excellent examples can be produced in 48-sized pots. They are very suitable for furnishing the stages and for general decorative work. Where several are grown in pots they should be wintered in the 48-sized pots and early in the New Year be given a shift into 6in. or 7in. pots. Such plants will grow some 3ft. in height and are useful for furnishing the beds in the conservatory. The plants can be wintered in cold frames, giving them plenty of air on all favourable occasions. Or a cool, airy greenhouse where they can be kept well up to the roof glass affords ideal winter conditions for them.

Stocks are very useful for winter and spring flowering. Of course, for winter flowering, seed should have been sown during July, but if sown at this time they will flower during the spring. Seed should be sown very thinly, as they are very apt to damp off if the young plants are at all crowded. The seed-boxes should be stood in cold frames. When large enough to handle, the young seedlings should be pricked off, three or four being placed round the edge of a 60-sized pot. As a proportion of singles must be expected, this allows for them being pulled out. Of course, where space permits, it is best to grow them singly, one plant in a pot. They should be grown in a compost of good medium loam without any added leaf-soil. Lime is important for successful cultivation, and some old mortar rubble may take the place of sand. It is important that they be potted fairly firmly. They require perfectly cool treatment and very careful watering during the winter, and, like antirrhinums, may be wintered in cold frames or in cool, airy pits where they can be kept well up to the roof glass. The East Lothian varieties are very suitable for spring flowering, also All the Year Round, Sutton's Christmas Pink, Beauty of Nice and the many other beautiful varieties

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Climbing Plants (A. W., Birmingham).—If by perennial climbing plants our correspondent means those which die down to the ground in winter each year, then the choice of subjects suitable for a rather shaded northerly aspect is very limited. Tropæolum speciosum and Lathyrus latifolius in rosy red, pink and white should succeed. Trench the ground 2ft. deep, adding fibrous loam and leaf-mould if the soil is poor. The tropæolum in particular requires a light, well drained but moist soil. If deciduous woody climbers are required, prepare the soil in the same way and plant a selection from Rose Gloire de Dijon, Clematis Jackmani or C. Flammula, Forsythia suspensa and Jasminum nudiflorum.

Treatment of Border Carnations (W. M.).—No doubt the carnations have been eaten by slugs, which have been very troublesome throughout the summer. Sprinklings of soot or dry lime, applied separately, not together, would help to ward off attack by slugs. The latter should be looked for and caught at night by traps in the form of cabbage or lettuce leaves or bran. If carefully lifted, the old plants may be moved to another border. It is rather late to layer side shoots, but it may be done. Any seedsmen advertising in this journal would supply the seeds, which should be sown under glass next March or a little earlier.

MISCELLANEOUS.

Various Questions (R. R., Hitchin).—The markings on the leaves of the pear are caused by a fungus. The present season has been favourable to the spread of this disease. In a normal season it is not so prevalent. Prevention is best, and it is a wise plan to spray with Bordeaux mixture in the spring. The trees should be shaken from time to time now, and the fallen leaves collected and burned. The violas are attacked by a fungus, very common this year. Keep the soil on the surface loosened frequently and the bed free from weeds: it is all that can be done now, as the season is advanced. The leaves are also suffering from the leaf-mining maggot. Next year, in spring, scatter a small quantity of soot among the plants, which will benefit them and keep away the maggot fly. In the autumn thoroughly rake the lawn surface, apply well rotted manure and wood-ashes freely, and half a pound of lime per square yard. Sow hard fescue grass seeds next March.

Violas and Pansies (J. M.).—The viola and pansy are one and the same species, and are difficult to define. They chiefly differ in size and marking, the viola being smaller and mostly self-coloured. The pansy is a garden development, with larger flowers of various colours, some with definite markings and blotches.

Names of Plants.—R. M'K.—1, Deutzia crenata flore pleno; 2, Borago officinalis.——H. G. S.—Ruscus Hypoglossum.——J. M.—Rose Fimbriata.

Names of Fruit.—D. M.—Apples: 1, Endsleigh Beauty; 2, Alfriston; 3, Bramley's Seedling; 4, Beauty of Bath.

RULES FOR THE ROSE COMPETITION

A list of six (only) hybrid tea roses to be sent in in order of preference on a separate sheet of paper, with name and address of the sender clearly written on the top. No ALTERNATIVES WILL BE ALLOWED, but readers may send in any number of lists.

Lists must reach this office not later than Saturday, September 20th (after that date no lists will be accepted) and must be accompanied by a coupon, to be found on page ii of this issue, and also in the issues of August 23rd and 30th, and September 13th.

The popular vote will be final, and no correspondence will be entered into over this competition.

Envelopes must be marked COMPETITION and addressed to THE GARDEN, 20, Tavistock Street, Covent Garden, W.C.2.

The Editor will not be held responsible for letters missing in the post.

The First Prize will be an order for £3 on any advertiser to be found in the pages of THE GARDEN.

The Second Prize will be an order for £2 on any advertiser to be found in the pages of THE GARDEN.

The Third Prize will be a book, or books, from the *Country Life* Library to the value of £1.

The result will be announced in THE GARDEN in the issue of October 11th.

The Editor's decision on all points will be final and binding.

See THE GARDEN, *August* 23rd, *page* 578.

GENERAL LIBRARY
SEP 23 1924

Vol. LXXXVIII.—No. 2756 Saturday, September 13th, 1924 Price THREEPENCE

The Kelway Colour Border

The formation of actual scenes of beauty with living subjects abounding in interest individually would seem to be a pleasant and worthy amusement, and one as full of dignity as the portrayal of such scenes on paper or canvas.
The late Dean Hole truthfully wrote in *Our Gardens:* "There has been no introduction which has had such happy and universal influence in extending and increasing the enjoyment of a garden as the HERBACEOUS BORDER." One of the first remarks of one's hostess in the country nowadays is, "Would you care to see my new Herbaceous Border?"—or "my new KELWAY Border?"
Send dimensions of space to be filled, and the effect required, stating aspect and soil, and asking any questions.

WRITE NOW to the inventors of Colour Borders:

THE GARDEN

VOL. LXXXVIII.—No. 2756. SEPTEMBER 13, 1924.

We would ask our readers to remember that "The Garden" is produced for the benefit of all gardeners. We are always pleased to consider articles or notes on any horticultural subject. We are also here to answer questions.

About a century ago there was a craze in this country for the Cape heaths. The number of varieties in cultivation in greenhouses was enormous. Now, alas, most of them have disappeared. This illustration, however, shows one which is still popular, Erica hyemalis.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

PLEASE MENTION "THE GARDEN" WHEN ANSWERING ADVERTISEMENTS.

SEEDS AND PLANTS FROM OVERSEAS

II. - PLANTS.

THE problem with the despatch of plants to this country from overseas is entirely different from that of seeds, and is considerably simpler, for we know to begin with that there are numbers of plants which will not live through a long journey either in the temperate zone or through the tropics.

We know, for instance, that plants with storage capacity within themselves, like most orchids, and succulents like mesembryanthemums and cacti, withstand even the longest journey comparatively easily. We know too that corms, bulbs and tubers are perfectly happy if sent at the right time and packed dry. We also know that it is impossible to send leguminous and other plants of that nature.

The problem therefore resolves itself into three factors :- -

1. Is it possible or not possible to keep a plant alive on a long journey ?
2. What is the best time to send a plant ?
3. What is the best way to pack a plant ?

1. The first point depends largely upon point 3, and this will be explained in due course. As I said above, plants with storage and plants with root systems in the form of bulbs, corms and tubers, are comparatively simple. After that I should certainly say that ligneous plants were the easiest to send and also as a general rule perennials which die down to the ground in winter. Although numbers of bulbs and ligneous plants have been sent yearly from Japan with fair success for a number of years, little experience in the despatch of plants has been gained since the Wardian case has more or less fallen into disuse, but of this more in point 3.

2. The best time to send a plant is obviously when it is at rest, but then a resting period is often a long one and I should say that as a golden rule it should always be lifted at the beginning of the resting period and not at the end, for plants are creatures of habit and when they feel the necessity for growth come upon them they will come into growth wherever they may be, unless the checking is severe, and this brings me to No. 3.

3. Our grandfathers, with the help of a gentleman called Mr. N. B. Ward, used to transport living and growing plants in a contrivance called a Wardian case, which was nothing more nor less than a movable frame with glass top and sides. The whole secret of the contrivance was that it was practically airtight and so there was little or no evaporation of moisture while sailing through the tropics. It is known that on several occasions plants were shipped from China to England, via the Cape, and survived without even having been watered on the voyage. As I said the other week in an article on Robert Fortune, it was due to the Wardian case that he was able to start the tea industry in India. The top of the case was movable so that if condensation on the inside became excessive a little air could be let in to counteract it.

A Wardian case, however, was clumsy and liable to damage. Surely Dr. Cockayne's suggestion in his article last week is the logical solution of the difficulty of bringing home plants alive? He suggested that the cool-rooms of ships might be used, always supposing that the shipping companies would allow it. There is hardly a ship nowadays which has not got a room used for storing fresh fruit and vegetables for use on the voyage. It is kept between 33° and 35° and is surely an ideal place for all plants, except the most tender, on a long voyage. The temperature is always steady and if the plant is collected in the resting season there will be no stimulus to start it into growth on entering the tropics. Most plants could be lifted with a ball of the original soil around their roots, thus saving root disturbance, and either packed in a crate or simply in sacking and in the cool room it would remain undisturbed until its arrival in England. The only surprising thing is that this method of transportation has not been used hundreds of times already.

It also seems to me that transportation of seeds in a cool-room, or in the case of high alpines, in the refrigeration chamber of a ship, might improve the germination of seeds owing to their having travelled in a stable temperature. At any rate I am sure that by this method a number of plants from the temperate zone which have so far refused to reproduce themselves by their seed germinating in this country, might be lulled into a sense of security on the voyage. What they would do when they found themselves alive in our gardens is another story.

E. H. M. C.

A REMINDER.

Remember that this is the last issue which contains the coupon for our Rose Competition, and also that all entries must reach this office by Saturday, September 20th. The rules will be found on page 640 of this issue.

CHRYSANTHEMUMS

THE GENERAL CULTIVATION OF THE PLANTS IN LATE SUMMER AND AUTUMN.

CHRYSANTHEMUM blooms may be obtained, on plants that are well grown, from late in June to the end of January—seven months out of the twelve. I do not think many cultivators would wish to have blooms over a longer period, not even the enthusiasts, as there is always so much pleasure in welcoming the new-comers when the various sections of plants unfold their flowers. But every part of the work in connection with the growing of the plants should be done well so that the very best blooms will result. The enthusiast, whether he is a cultivator of chrysanthemums, orchids, fruits or flowers, always takes a deep interest in the plants at all stages of growth, but the deepest interest comes when the flowers or fruits, as the case may be, are nearing perfection.

Splendid displays of flowers may be secured without the aid of glass and it is this fact that, perhaps, goes a long way towards earning for the chrysanthemum the title of "Autumn Queen." In every garden, in all kinds of soil, borders of these plants may be grown; there is, now, a wide range of colour and a great improvement in the habit of the plants and their blooms. Some of these gems are named below. But even the ideal plant may be spoiled if it is not properly treated. Staking of nearly every plant is essential now; some disbudding will improve many varieties, while those that are noted for their charming sprays should not be disbudded.

The staking should be just sufficient to support the plants and not mar their natural habit. Most of the single-flowered varieties that flower in the open border are taller-growing than the others and require more care in the staking. Frequently, one finds plants existing in borders, with all their lower leaves withered and the stems hard and wiry. They are starved, and have been throughout the summer months. Millions of blooms will develop during the months of August, September and October, and, perhaps, those most valued are the ones opening in the two last named months. The starved specimens may be improved considerably by the application of weekly doses of manure-water; two applications a week will be required by plants growing in a sandy or light soil.

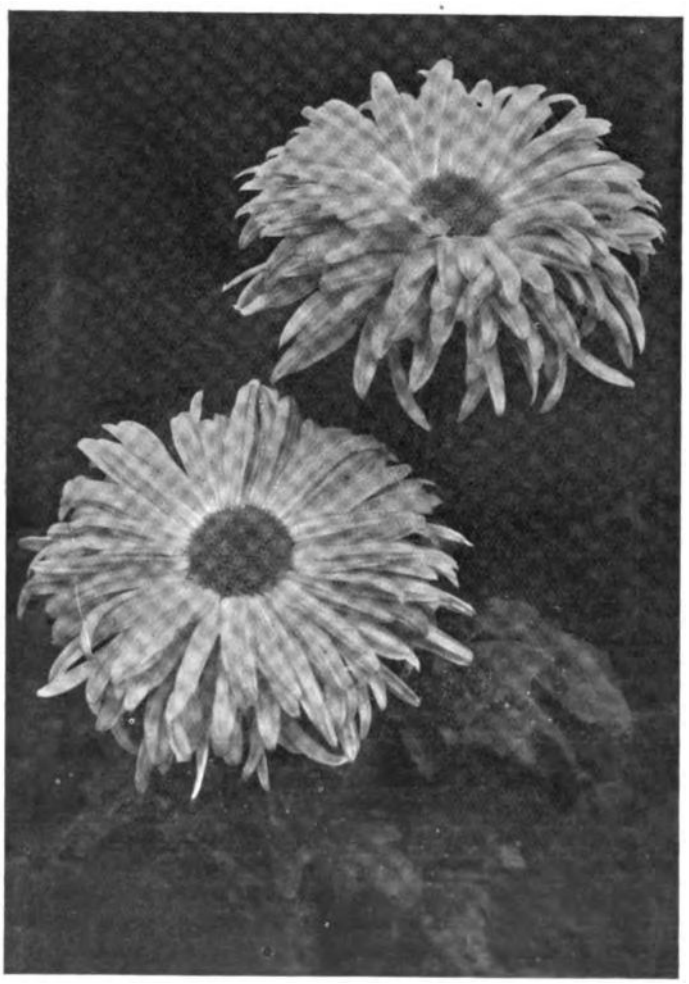
Note should be taken now of drawbacks, such as wrong positions, bad arrangements of colours and grouping, also of the various heights of the plants, so that all mistakes may be avoided next year when new arrangements are made. For the benefit of those growers who have not given the varieties a trial, I will name a few of the best of the newer ones here. I think the best effect is obtained by planting in masses and confining the colours, as distinct as possible, to about a dozen. Almirante, reddish scarlet; Cranfordia, yellow; Bronze Cranfordia; Countess, pure white; Emperor, crimson; Framfield White; Harry Thorpe, yellow, centre shaded fawn; Mrs. Marshal Field, hydrangea pink; Normandie, pale pink; Pink Delight; Silver Lining, silvery pink on white ground; and Verona, red. These are all real gems; so also are the following singles, suitable for the open border. Carrie Luxford, crimson; Dolly Thorpe, apricot and salmon; Early Mary Richardson, buff and gold; Fire King, crimson red; John Woolman, rose pink; King Cup, clear yellow; Midnight Sun, terra-cotta, shaded yellow; Pure Gold, deep yellow self; Resolution, deep rose-pink self; Simplicity, a very pure white; Shirley Crimson, velvety, good; Shrapnel, orange and terra-cotta.

Inexperienced cultivators wish to know when they should strike cuttings and plant out the resultant plants. Both sections, above named, should be propagated between the middle of February and the same time in March and should be planted out in the open border late in May.

PLANTS IN POTS.

Chrysanthemums are grown in pots so that they can be housed, and the blooms be available for cutting or for the furnishing of the greenhouse and conservatory after the open-air flowers have faded. Such plants are very precious at the present time and all cultivators of them should remember that the bulk of soil around the roots is small. Feeding is essential and must be attended to several times each week. Of course, it is advisable to keep the plants outside as long as safety from early frosts will permit. As the pots are now full of roots some nourishing food should be applied regularly, in weak doses often rather than in strong doses and at long intervals. In wet weather artificial manures, in powder form, may be applied and in dry spells liquid manure should be applied alternately. In country districts farmyard liquid manure will be available or the organic manures which can be placed in bags and soaked in tubs of water. In towns and their suburbs soot-water will be available and organic manures in some districts. Horse, cow, goat, sheep, fowl and pigeon manures are all suitable.

Only in cases where fairly large blooms are required on these small plants will it be advisable to disbud and retain crown buds; the greatest satisfaction is derived from the retention of the terminal buds. Here, again, we should



A SINGLE-FLOWERED VARIETY, CHRYSANTHEMUM PINK BEAUTY.
The form is more attractive than the colour.

Digitized by Google

be careful not to disbud those specimens that bear blooms in spray form.

Earwigs are very numerous this year and a careful watch for them every night is necessary and the examination of traps every morning. The stems of broad beans, empty flower pots with a little moss in the bottom, placed on the ground, and old dahlia blooms fixed half-way up the stems of the plants all form useful traps. The plant bug, or hopper, eats the stems just below the bud. When first seen the plant bug jumps quickly, but if carefully watched it may be caught the second time, as it rarely jumps as quickly, but turns round on the leaf or other object. Every plant should be well cleaned, also pots, before they are placed under glass.

The varieties named below have given great satisfaction last year and this; they are suitable for both large and small greenhouses.

Framfield Glory, deep golden yellow, one of the finest for pots; Ivy Gay, clear pink; Lady Stanley, silvery pink; Lucie Loupee, pure white; Red Dragon; Mrs. Sydney Dove, rich pink; Pink Profusion, lovely for table decoration; Romance, yellow, old and still good; Lord Brooke, bronzy-orange; Mme. R. Oberthur, late white, always reliable; Pink Pearl, rich pink; Shirley Scarlet, one of the best; Thorpe's December Pink.

Single-flowered: Bertha Fairs, orange and bronze; Ceddie Mason, crimson; Flossie, bright yellow; Glorious, golden yellow; Jessica, red; J. J. Morrish, golden yellow in sprays; Mary Richardson, reddish salmon; Molly Godfrey, rose pink; Phyllis Cooper, golden yellow, superb; Sweet Auburn, orange and fawn, and Pink Beauty, the form of which is more attractive than the colouring. Mensa, best white.

A PRETTY LATE FLOWERING JAPANESE VARIETY, C. BRIGHTNESS.

INCURVED VARIETIES FOR DECORATION.

About thirty years ago the incurved sorts were extensively grown both as specimens and for cut flowers. Few of the varieties grown then are cultivated now, but there are several newer ones that are refined in flower and satisfactory in every way. The cuttings should be propagated early in February and the resultant plants flowered singly in 7in. and 8in. pots or three in a 9in. pot. Stopping is not necessary nor desirable. Practically all the plants grow bushy in form and bear the best blooms on terminal shoots; so it is only necessary to propagate at the right time, re-pot in due course, take terminal buds and feed judiciously during August, September and October. The flowers of the following are available from September to Christmas:

Romance, golden yellow; Golden Glory, deep buttercup yellow, a grand flower; Charles H. Curtis, clear yellow; Edwin Thorpe, pure white; Emblem Poitevine, golden yellow, late; H. W. Thorpe, pure white, November flower, easy to grow; Mrs. F. Judson, another grand white; Mrs. Sydney Dove, pearly pink, perfect; Percy A. Dove, white, end of November; Mme. Ed. Roger, sea green, a novelty; W. D. Parkins, rosy mauve; and W. J. Higgs, rich crimson.

Groups of these distinct colours embodied in perfectly-formed refined flowers will make a greenhouse attractive, or, as cut flowers arranged in tall trumpet-shaped vases, the dwelling-room or hall.

BUSH, OR SPECIMEN PLANTS.

I strongly advise cultivators not to attempt growing specimen bushes unless they are prepared to devote considerable time to training, etc. From the cutting to the flowering stage the plants must receive special attention. They should never receive a check to growth nor be allowed to get pot-bound before the final potting and, afterwards, feeding will be essential to success; throughout, extra care is needed in the matter of watering. Most of the plants will need stopping twice—in April and late in June—to induce a branching habit. William Turner, white; Edith Cavell, chestnut; Louisa Pocket, white; Mrs. G. Monro, Junr., deep crimson; Mrs. Algernon Davis, pink; Mrs. M. Sargent, greenish white; Mrs. R. Luxford, Indian red; Peace, buff yellow; Mrs. R. H. B. Marsham, white, all Japanese varieties; with H. W. Thorpe, white; Mrs. Sydney Dove, pink; Mme. Ferlat, white; W. J. Higgs, crimson, all incurved. Mensa, white; Glorious, yellow; and Ladysmith, shell-pink, are ideal singles for bushes.

LIFTING PLANTS FROM OUTSIDE BORDERS.

This is frequently done and the flowers serve a very useful purpose, but they do not last as long, quite, when cut, as those from pot-grown plants. If dry, the soil should be watered the day before the plants are lifted. Also, the plants are best when lifted soon after the buds have formed. The re-planting should be done quickly and in a border or in soil packed on a stage. Water forthwith, shade slightly for a week and syringe the foliage daily in bright weather, then gradually expose to light and sunshine, keep the foliage dry and ventilate freely. The plants may be lifted and placed in pots in the usual way, then treated as advised above.

GENERAL TREATMENT OF PLANTS UNDER GLASS.

Water early in the day. Ventilate freely in fine weather; use fire heat only to expel excessive damp and frost; catch earwigs at night, fumigate to kill black and green aphides, and use flower of sulphur to destroy mildew. Do not feed plants that bear blooms three-parts developed, clear water is sufficient then. Remove suckers till November 1st.

GEORGE GARNER.

AUTUMN COLOUR in the SHRUBBERY BORDER

WHEN planting beds and borders of hardy shrubs for effect in autumn, there are three or four phases of plant beauty and interest to be borne in mind. Only a comparatively few shrubs flower in autumn, but the leaves of many deciduous shrubs assume gorgeous tints of colour before they fall. Some of these shrubs, particularly in the autumn sunshine, rival, if they do not surpass, many bushes in flower. In addition to these we have an increasing number of hardy shrubs with very showy fruits; the newer Chinese barberries and their hybrids being notable examples.

In gardens of private houses where the owners are usually resident in autumn and in public parks and gardens of holiday resorts, these shrubs possess a special value. Until midsummer, or a little later, there are so many and such a wide variety of shrubs in flower that it is easy to keep the flag of interest flying. There is no reason why, with a little consideration and planning, the shrubbery beds and borders should not be just as interesting from mid-July and onwards throughout the autumn.

While the amount of foliage-colouring and fruiting varies from year to year, with such a wide variety, the prevailing climatic conditions invariably suit a goodly number, and quite a nice list can be made of those of which it may be truthfully stated that whatever the weather, in flower, foliage or fruit they never fail to develop attractive features.

AUTUMNAL COLOURING.

Speaking generally the leaves of most deciduous shrubs change considerably in colour in late summer and autumn before they fall. The change from the varying shades of green to gorgeous tints of yellow, orange, red, crimson and intermediate colourings is most interesting to watch from day to day. The changeable conditions of the British climate have a considerable influence in varying from year to year the degree of rich colouring in certain shrubs. The nature of the soil also influences to some extent the intensity or otherwise of the colouring in different localities.

The hot dry summer of 1921 gave us a very good example of both climatic and soil conditions. On our light soil at Kew the colouring developed early and did not last as long as usual. Comparing notes with friends gardening on heavy rich soils came reports of the gorgeous colouring of many shrubs which under normal conditions called for no special comment prior to the falling of the leaves.

With a wide variety of shrubs from which to make a selection it is only possible to record here a few of the most striking and those which seldom, if ever, fail to attract attention.

The rhus or sumach family is of particular value, with R. cotinus the outstanding feature, a gorgeous study in crimson, scarlet and orange. A tall bush 8ft. to 10ft. or more in height, it colours best in the ordinary soil of the shrubbery border rather than deeply cultivated ground. The Japanese sumach, R. trichocarpa has attractive leaves more than 1ft. long, the leaflets of which change to brilliant orange-crimson. R. glabra, (rich red), and R. typhina, (orange and red) are very useful in the shrubbery borders of town squares.

As a lawn tree or in the shrubbery border Amelanchier canadensis is attractive in yellow and red. Half a dozen of the best deciduous barberries with us in autumn are Berberis concinna, B. dictyophylla, B. Thunbergii, a study in scarlet and gold, B. vulgaris, B. Wilsonæ and B. yunnanense, orange, red and crimson. In the autumn of 1923 we had nothing finer in colour than Enkianthus campanulatus, gorgeous in red and yellow leafage, fine in a mass. The best of the flowering currants are Ribes aureum and the variety aurantiacum with rich dark red colouring. R. americanum is also good.

Many of the deciduous hybrid rhododendrons (azaleas) change to rich tints of crimson, scarlet, red, dark orange and yellow before the leaves fall. R. dilatatum, orange red, is particularly showy among the species. Fothergilla major, golden yellow; F. monticola, yellow and red; Disanthus cercidifolia, many vacciniums, especially the dark red V. Arctostaphylos, Viburnum Opulus, Pyrus cratægifolia and some of the Japanese maples give to the borders a wealth of colour in autumn.

A few of the smaller trees will find a place in the background or as lawn specimens, adding greatly to the beauty and interest of the garden landscape. First on the list must be Parrotia persica, crimson, metallic red, orange and golden yellow; Nyssa sylvatica, red; several thorns, particularly Cratægus Crus-galli, and C. prunifolia, both gorgeous in orange and red, also C. Carrieri, rich in autumn foliage and fruit until near the end of the year; Oxydendrum arboreum, red; Ginkgo biloba, yellow, and Waterer's Scarlet Oak, Quercus coccinea var. splendens.

ATTRACTIVE IN FRUIT.

The value of berried shrubs for making an interesting and bright display from August onwards in the shrubbery borders and pleasure ground in general is annually receiving more attention. No family of hardy shrubs is more promising to-day in this respect than the barberries, especially the hybrids of Berberis Wilsonæ, B. polyantha, B. subcaulialata and B. Staphfiana, which originated at Wisley and elsewhere. In this respect, too, we must include B. vulgaris, B. aggregata, B. Pratti and B. Beaniana. Autumn rains and winds may damage the flowers of the garden roses, but the hips of the wild roses glisten brighter than ever in the sun after rain. In addition to the British Rosa canina, RR. Webbiana, Moyesi, sertata, omeiensis, Davidii and glutinosa, deserve special attention.

As large bushes, a blaze of colour with autumn fruits, the pyracanthas are very prominent, none more so than P. coccinea var. Lalandii, which is equally valuable as a bush or climber for the wall of the suburban villa. The cotoneasters, mostly with red fruits, viburnums in variety, especially V. betulifolium, V. dasyanthum, V. Henryi, V. Opulus, and the distinct yellow fruits of var. fructu-luteo and V. Lantana, with the fruits at first red, then black.

Altogether there is no necessity then for the shrubbery to look dull and dismal throughout late summer and autumn provided one makes a selection of shrubs from those given above. A. O.

ONE OF THE BEAUTIFUL COTONEASTERS WITH ITS HANDSOME BERRIES.

NEW ZEALAND PLANTS FOR THE BRITISH ISLES

BY DR. L. COCKAYNE, F.R.S.

IN THIS ISSUE DR. COCKAYNE CONTINUES HIS SUGGESTIONS OF SEMI-WOODY NEW ZEALAND PLANTS WHICH MIGHT PROVE AMENABLE TO CONDITIONS IN THE BRITISH ISLES.

(*Continued from page* 616.)

4. Astelia.

A. Cockaynei (sea-level to 5,500ft., on fairly deep soil, often stony, in full sunshine, sphagnum bog, forest floor) is a handsome, easily grown, liliaceous plant forming large whitish patches of spreading leathery leaves, silky on both surfaces and marked with a conspicuous central and lateral brown lines. A. Petriei (3,000–6,000ft., in hollows where snow lies long) is similar, but the leaves shorter, glossy pale green and glabrous. A. monticola (4,000–6,000ft.), grows in similar situations to the last named, but the leaves are smaller still and gradually taper into long points; not yet in cultivation.

5. Celmisia (cotton-plant, mountain-musk for certain classes).

The genus consists of about fifty-five species and a number of natural hybrids, all of which are endemic, but Australia possesses an additional species. They are nearly all showy, often stately herbs, bearing, usually on long stalks, daisy-like flower heads, frequently of great size. Here the species are arranged into three groups.

(*a*) With large leaves covered beneath with a mat of hairs, often white, arranged in erect rosettes (the cotton-plants).

C. coriacea (3,000–5,000ft., on rather stony ground in full sunshine) has flowers up to 4ins. diameter and stiff, broad, silvery, lance-shaped leaves up to 2ft. long. C. Hookeri (sea-level to 4,000ft.), with fringed rays to heads equally large, has broad, soft, pale green leaves, white beneath. C. verbascifolia (1,000–4,500ft., from stony ground to sphagnum bog), is similar, but rather smaller. C. lanceolata (2,000–4,000ft., on wet mountains in the south), has moderately broad, dagger-like leaves marked by a median orange line; its heads are about 2ins. in diameter. C. Armstrongii is similar, but with narrower leaves. C. Petriei (4,000–5,000ft.) has also narrow leaves, but they are glossy green, satiny-white beneath, and ridged longitudinally. C. Traversii (3,000–5,000ft., rather stony ground) has soft, dark-green, broad leaves, margined conspicuously with velvety rust-coloured hairs, and the mat of hairs on the back of the leaf also more or less rusty. C. rigida (coast Stewart Island—2,000ft.; rock, stony soil) is similar, but the mat of hairs is white; it is very easy to cultivate. There are numerous hybrids in this group, in which C. coriacea, C. Lyallii, C. petiolata, C. Traversii, C. spectabilis and C. gracilenta are concerned.

CELMISIA ARMSTRONGII GROWING IN ITS NATIVE HABITAT.
The plant makes a firm and sturdy growth.

(*b*) Forming mats, often more or less circular, with spreading, rooting, leafy branches, and mostly linear, oblong or spathulate aromatic leaves, frequently in close rosettes; the flower heads 1in. to 2ins. diameter on slender stalks (the mountain-musks).

This class, not much in evidence in British gardens, would be a valuable addition to them; the species have the advantage of being readily propagated from rooted pieces of the stem. They mostly grow on stony ground at altitudes of from 2,000–6,500ft., and many are common on the drier mountains. The most beautiful and showy is C. incana (there are many forms) with its leaves covered with snow-white wool on both surfaces. C. intermedia is similar, but grey and not woolly on the upper surface. Other species are C. Sinclairii; C. Lindsayi (coastal cliff), larger in all its parts than most of its section and easy to grow; C. prorepens, with wrinkled, green, thin, glabrous leaves; and C. densiflora, similar to the last, but with a white kid-glove-like mat of hairs on the back of the leaf.

(*c*) Cushion plants with small leaves in close rosettes; flower heads rather small, but numerous.

These are frequently plants of stony ground at a high altitude—6,000ft. and more. C. Hectori makes wide circular mats, or cushions, of crowded, silvery rosettes of small, rather narrow leaves; the flowers are on short stems; it is an ideal rock-garden plant. C. sessiliflora (3,000–6,000ft., often abundant on wet peat) forms dense silvery cushions; the flowers are stemless. C. argentea (sea-level in Stewart Island to 6,000ft. in the South Island, wet peat) is similar, but the leaves and rosettes are smaller. C. laricifolia (3,000–7,500ft.; extremely stony ground), has tiny rosettes of very narrow, pointed, silvery leaves. C. bellidioides (1,000–4,000ft., wet rock faces) forms close, bright-green cushions of small glabrous leaves; its numerous daisy-like flowers are held well up on long stalks.

The sub-antarctic C. vernicosa belongs to section (*b*), but so wonderful a plant must stand by itself. The short, narrow, stiff leaves, in crowded rosettes, are like highly polished jade; the heads, 1½ins. diameter, are lovely with their spreading white rays and purple disc, or occasionally they are purple throughout. It grows on wet peat and is exposed to almost constant cold sleety gales, but the ground is barely frozen in winter, and the summers always cool. Evidently this delightful plant will be extremely difficult to cultivate. Possibly pot culture in a cold frame would succeed best. C. campbellensis is similar to C. vernicosa, but the leaves are lance-shaped.

6. Chrysobactron (syn. Bulbinella, Anthericum).

C. Rossii, growing under similar conditions to its sub-antarctic companions, well upholds the reputation of that wonderful little flora. It has a fleshy rootstock, from which arise yearly numerous broad hyacinth-like, fleshy, bright green leaves; the striking orange flowers, held aloft on long stalks, are in racemes, 4ins. long, the male being far the more showy. Hillsides in Campbell Island bedecked with this magnificent plant in its thousands are a treasured memory. C. Hookeri (sea level to 4,000ft., both extremely wet and equally dry ground) is smaller, its pretty flowers yellow and its cultivation simple.

7. Coriaria angustissima (1,000–4,000ft., stony river bed) is worth cultivation on account of its green, feathery foliage and masses of black fruits. As it dies to the ground in autumn it should withstand most frosts. In cultivation it requires a good soil of a fair depth.

Digitized by Google

8. Cotula.

C. pyrethrifolia (3,000–6,500ft., on stable screes), makes dense mats of small, fleshy, aromatic, much-cut leaves; the heads are cream-coloured and 1-in. diameter. C. squalida, C. potentillina (Muelleri), C. Traillii (coastal), and C. Haastii, are pretty mat plants of rapid growth, with small fern-like green leaves. The sub-antarctic C. plumosa (coastal), has beautiful, erect, feathery leaves with filiform segments.

9. Donatia novæ-zelandiæ (sea-level Stewart Island to 6,500ft. in the South Island), builds large dense green cushions, made up in part of its rotting parts, dotted thickly with pretty white flowers. The species of Phyllachne, similar in form but the cushions smaller, are even more floriferous.

10. Drapetes Dieffenbachii (1,000–6,000ft.; stony ground in full sunshine), of easy culture, forms close, pale-green mats with minute leaves and abundant small white flowers, an excellent "alpine."

A DIFFICULT PLANT TO GROW, THE DENSE GREEN CUSHIONS OF DONATIA NOVÆ-ZELANDIÆ.

11. Gentiana (gentian).

The twenty species are all worth growing, but they are very difficult to establish. Possibly, were seed sown in a small pot and when the plants were pot-bound, should such good fortune come about, soil and all were transferred to a suitable position, the plants might be established. G. corymbifera (1,000–4,000ft., in fairly deep soil) is to be greatly desired, with its umbels of delicate white flowers, each 1in. diameter, raised 2ft. above the rather insignificant rosette of leaves. G. divisa var. magnifica (3,000–4,000ft., in clayey soil in full sun) forms rounded cushions 6ins. diameter, completely covered with large, snowball-like white flowers. G. bellidioides and G. patula are also excellent.

But the glory of these gentians culminates in the glossy-leaved, sub-antarctic G. cerina, with the flowers ranging from white to crimson.

12. Geum uniflorum (3,000–5,000ft.; on moist, shady banks, along with Celmisia Walkeri), is a beautiful evergreen, woody at the base, with brownish leaves in a rosette and stalks 5ins. long, bearing large, solitary white flowers.

13. Gnaphalium (cudweed).

G. Lyallii, G. trinerve and G. Keriense are pleasing, much-branched plants of similar appearance and requirements, forming depending mats with soft, green leaves, white beneath, on wet banks and in the drip of water; the numerous flowers are "everlastings." G. subrigidum (lowlands, wettish marl banks), less hardy, has much narrower leaves, and grows more slowly, but a charming plant.

14. Gunnera.

As the South American gunneras are the giants, so are the New Zealanders the pygmies of this genus. All the latter form carpets of small, broad leaves in rosettes. G. dentata, with red fruits on erect stems, reminds one of a grape-hyacinth. G. Hamiltonii is pleasing with its brownish rosettes.

15. Haastia.

Doubtless many would like to grow the great vegetable sheep (H. pulvinaris), a plant of screes at 5,000ft. and upwards on dry mountains, but, except for a piece kept alive in a greenhouse for some time, it has not been successfully cultivated. The desirable H. recurvum and H. Sinclairii, forming respectively brownish or greyish mats on screes at a high altitude, are amenable to culture, but not easy.

16. Helichrysum.

H. bellidioides is well known in British gardens, but there are many forms differing in the degree of silveryness of leaf. The North Island variety of H. prostratum, with its larger leaves, and more or less stalkless flowers, is of high excellence. H. Sinclairii (3,000–4,000ft., on shady rock faces; not yet in cultivation) is a charming, erect plant 1ft. to 2ft. high, with much-branched, white woolly stems, small leaves and bunches of everlasting flowers.

17. Jovellana (Calceolaria) repens (lowland and montane in drip of water), is a very pretty, small, mat-forming plant with the flowers 1in. diameter, white, spotted purple. J. Sinclairii (not so hardy), of a similar habitat, but will grow well in a dry situation, is of erect habit, and larger in all its parts.

C. VERBASCIFOLIA. AN ILLUSTRATION OF HOW CELMISIAS GROW IN THE WILD STATE

SCOTLAND'S PREMIER FLOWER SHOW

GLASGOW SHOW is probably the premier Show in the British Isles after Chelsea. The reason is partly that Scotland is a land of gardeners and partly because of the Kelvin Hall in which it is held. This hall is the old machinery hall of the Glasgow Exhibition and without a doubt it is the finest hall in which a flower show could be held.

People who visit the Glasgow Flower Show for the first time will be amazed at the extent of space which it covers and the numbers of exhibits, for to my mind this is the ideal of what a flower show should be, a judicious blending of purely trade exhibits, and classes both open and limited to amateurs. In this way every class of the gardening world is catered for, and the consequence is that everybody is satisfied.

Naturally, in a show so large as this it is impossible to describe every exhibit or class, but to show the variety of classes open to amateurs I can mention twelve blooms of roses, forty-eight blooms of roses, the former divided into sub-sections of different colours, twelve begonias, six, twelve and twenty-four violas, a vase of double asters, six vases gladioli, three vases hardy herbaceous, numerous classes of early chrysanthemums, bowls of roses and vases of carnations and sweet peas for decoration, tables of fruit, table decoration, besides dozens of classes for fruit and vegetables. The standard was amazingly good considering the season, so good that it was very difficult to pick out individual merit.

Mr. James Smith staged six excellent vases of border carnations and picotees, among them Kelso and Mrs. Hawksbee, as well grown as I have ever seen. He gained a well deserved first prize for this exhibit. Among the rose exhibits Messrs. Adam and Craigmile of Aberdeen received first prize for forty-eight magnificent blooms, which showed first-class cultivation. Another well merited first was given to Mr. G. T. Anderson, gardener to the Earl of Balfour, for his table of fruit. The most disappointing class was that of table decoration, which followed the old stereotyped rules and lacked originality throughout. Among sweet peas Mr. John A. Grigor, Duff House Gardens, carried off several firsts for excellent vases well arranged.

A GLIMPSE OF MESSRS. ADAM AND CRAIGMILE'S MAGNIFICENT ROSE BLOOMS.

To my mind the premier exhibit in the Show was that of the Glasgow Corporation Parks Department, who staged a formal garden, a fountain surrounded by beds the whole flanked by herbaceous borders. The exhibit was in excellent taste and reflected great credit on Mr. Matthews and those under him.

It is exceedingly difficult to stage rock gardens on a hard floor and in a confined space, but almost all shown were successful. Mr. Maxwell M. Hart staged the most ambitious garden, a square rising in the centre to a little plateau, on which was placed a summerhouse, the one blot in an otherwise excellent exhibit. Messrs. Kent and Brydon were less formal and just as successful, while alongside their rock garden was a charming herbaceous border. Messrs. Backhouse of York showed a simple and well designed rock garden. As I have said, it is impossible to mention even a tithe of the exhibits. In roses Messrs. Samuel McGredy of Portadown had the most noticeable stand. As far as I could see there were no novelties, but what was staged showed very good cultivation. Another fine exhibit of roses was that of Messrs. Dicksons, the well known Edinburgh firm. Messrs. Forbes of Hawick had a fine exhibit of their well known phloxes and pentstemons.

Messrs. Isaac House of Bristol showed their charming perennial scabious. There are few flowers in the garden which have such perfect tones of blue and mauve. This exhibit was very successful and will no doubt go a long way towards making these flowers more popular in our gardens.

Dahlias were very much to the fore, and were surprisingly good considering the vile weather we have been having. Mr. Woolman had the most attractive exhibit, showing every kind and variety, closely followed by Mr. M. Campbell of Blantyre, who also showed carnations. It is not common knowledge that dahlias were first introduced into this country as an article of food during a potato famine about 150 years ago.

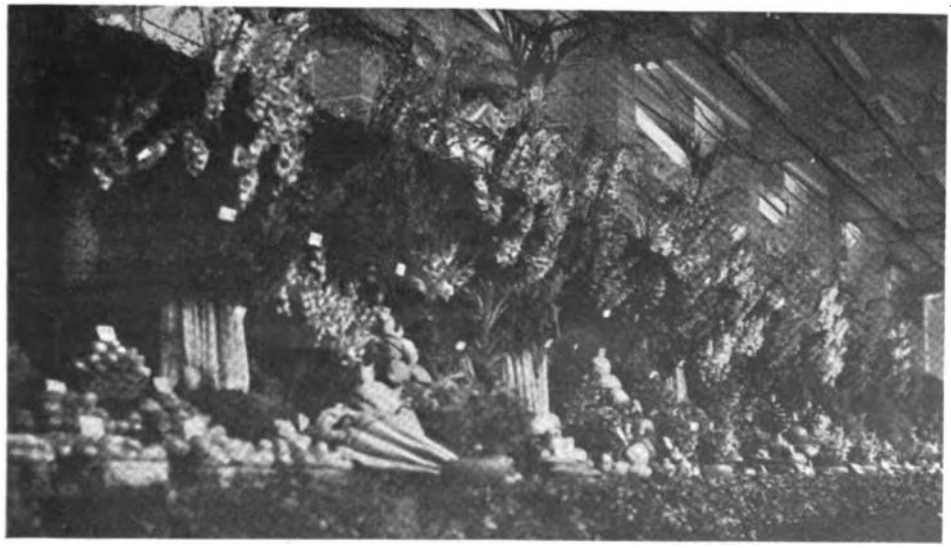
Mr. James Vert had a fine exhibit of his famous double hollyhocks. The colours are delicate and charming, among them I noticed particularly Olivier Chater, cream flushed pink, and Constance, salmon. Messrs. Lowe and Gibson again staged their fine strains of gladioli.

Fruit was more in evidence in classes than in trade exhibits, but The Carse of Gowrie Nursery Company and Messrs. Storrie and Storrie, both of them Perthshire firms, showed that Scotland is little, if any, behind England in the production of good table fruit. The fruit in both cases showed excellent cultivation and was well shown.

For vegetables the main exhibits were staged by Messrs. Sutton, Messrs. Kerr and Co., and Messrs. Austin and McAslan, the last firm also had an excellent exhibit of trees and shrubs, many of them distinctly uncommon; their exhibit of potatoes was also most comprehensive.

One other firm must be mentioned and that is Messrs. Dobbie, who had a large collection of everything which is in flower in our gardens at the present time.

Altogether this is one of the most successful shows that I have ever seen. This description is meagre, but I would not have missed visiting Kelvin Hall for worlds. E. H. M. C.



A WELL ARRANGED EXHIBIT OF VEGETABLES RAISED BY MESSRS. AUSTIN & McASLAN.

SEASONABLE JAMS AND JELLIES

THE "high summer" fruits are over, but there are still seasonable fruits, some growing wild, which may be gathered from the hedgerows and countryside, also vegetables which make excellent jams and jellies and are appreciated additions to the store cupboard.

It is not proposed to discuss here the general methods, apparatus and necessaries for making and bottling jams, of which most housewives have had experience, but just to give a few recipes, including those for jellies, which may be an addition to their collection of recipes. Jelly-making is one of the easiest methods of preserving fruit, and, as in making jam, the fruit must be *clean, dry, sound* and *not* over-ripe; this to ensure a good colour, full flavour and certainty of setting. Pectin, the body in fruit which enables it when boiled with sugar to set in the form of jam or jelly, is more abundant in *slightly* under-ripe than in *dead-ripe* fruit. Good preserving sugar is also essential and at the same time an economy, for it ensures clearness and less skimming. As in jam-making, sugar must be thoroughly dissolved before the fruit juice reaches boiling point. Absolute cleanliness is likewise a *sine quâ non* if good results are to be expected. A fairly coarse cloth or a fine hair sieve is required for straining. It is better to let fruit juice drip through overnight. Squeezing it causes the jelly to be cloudy.

DAMSON JAM.

Proportions.—To each pound of fruit allow ¾lb. to 1lb. of preserving sugar and ½pt. of water to every 6lb. of fruit.

Remove stalks, wash and dry the fruit, put it into the preserving pan with the water and let it stand over a gentle heat until some of the juice is extracted. Boil for ten minutes, then add the sugar, let it dissolve gradually, bring to boiling point and boil for another twenty or twenty-five minutes until it sets when tested. During the cooking remove as many of the stones as possible and just before removal from the fire add a few of the blanched kernels. Put into jars and cover in the usual way.

Plum jam is prepared similarly except that the fruit can be split and the stones removed, provided they come away easily, otherwise it is wasteful; if not, remove as the jam is boiling.

DAMSON CHEESE.

Proportions.—To each pint of pulp allow 12oz. to 16oz. of preserving sugar, according to acidity of fruit and individual taste. Remove stalks, wash and dry fruit, put it into a covered earthenware crock or jar, place in a pan of cold water, the water reaching rather more than halfway, or in a very slow oven and cook until the fruit is perfectly soft. Rub through a fine hair sieve; measure the pulp, put it into a preserving pan and add the sugar. Boil until the pulp becomes rather stiff, stirring very frequently and continuously as the liquid evaporates since at this stage it burns very readily. Turn into clean, dry, warm jars and proceed as in jam.

DAMSON JELLY.

Proportions.—Allow ¾lb. to 1lb. of sugar to each pint of fruit juice.

Choose ripe fruit, proceed as for damson cheese. When the fruit is quite soft strain through a cloth or fine hair sieve. Add the required amount of sugar, boil together until jelly sets when tested as for jam, skim if necessary.

BLACKBERRY JAM.

Proportions.—To every pound of fruit allow ¾lb. of sugar and nearly 1 gill of water.

The berries should be picked on a dry day; these should be ripe and juicy. Remove stalks and discard any unsound fruit. Cook the berries gently in the water for about twenty minutes. Heat the sugar in the oven (this hastens the period of boiling), then add the berries, allowing it to dissolve before the jam is brought to boiling point and boil for about forty minutes. Test in the usual way. Just before removal from the fire add a little lemon juice, about one dessertspoonful to 4lb. of fruit; this is an improvement to the flavour. Put into clean, dry, warm jars and cover at once.

BLACKBERRY OR BRAMBLE JELLY.

This being seedless, is often preferred to jam, particularly for children.

Proportions.—Equal quantities of fruit juice and sugar.

Put berries into an earthenware jar with a cover, stand in a pan of cold water and cook slowly until the fruit is quite soft and the juice extracted. Bruise them from time to time to extract it. Strain the juice through a jelly cloth or very fine hair sieve, bring to boiling point, boil for five minutes, add the sugar and boil until jelly sets when tested. Skim if required.

APPLE JAM.

When there are apple trees in a garden there is usually a certain amount of fruit (windfalls and others) which is neither suitable nor in a fit condition for storing, some of which may often be wasted if not quickly utilised. Such make quite good jam; but if apples are used alone it is rather uninteresting even when flavoured with ginger or lemon rind, whereas it is very palatable and of an excellent flavour if made with blackberries or cranberries, using half the quantity of either of these fruits to a given quantity of apples.

APPLE AND BLACKBERRY JAM.

Ingredients.—4lb. of apples, 2lb. of blackberries, 5lb. of preserving sugar, 1 gill of water.

Pick over blackberries, remove stalks and put into an earthenware jar with 1lb. of sugar and leave over-night; then cover jar, place in a slow oven or in a pan of water over a low heat, and cook gently until the juice is extracted, then strain. Peel, core and slice apples thickly, add the water and rest of sugar, let this dissolve, bring slowly to boiling point, add the blackberry juice and boil for about forty-five minutes, test on a cold plate, pot and tie down at once.

APPLE AND CRANBERRY JAM.

Later on, when cranberries are in the market, the following makes an excellent jam:

Ingredients.—Half the weight of cranberries to apples and 1lb. of sugar to each pound of fruit.

Peel, core and slice apples, add just sufficient water to prevent them from burning and cook gently until reduced to a pulp. Pick over the cranberries, wash and dry, add the sugar and bruise the fruit well to extract juice and flavour, add to the apples and boil together, stirring frequently. Test in the usual way, pot and tie down.

PEAR AND APPLE JAM.

Pears as a jam are flat and insipid in flavour, but combined with other more acid fruits, such as apples and plum, they make a delicious jam or conserve.

Ingredients.—4lb. of pears, 4lb. of apples, rind of 3 lemons, 2 oz. of whole ginger, ¾oz. of cinnamon stick, 2 pints of water, 1lb. of sugar to each pound of fruit.

Bruise ginger, pound with the cinnamon stick, not too finely, add to the water, and boil until reduced to half to extract the flavour. Strain, add the required amount of sugar, heat slowly and dissolve, then add the pears and apples peeled, cored and cut into neat pieces. Bring to boiling point and boil until the jam sets when tested on a cold plate in the usual way. Place in clean warm jars and cover at once.

Digitized by Google

PEAR, PLUM AND APPLE MARMALADE.

Proportions.—Equal quantities of each kind of fruit, 1lb. of sugar to each pound of fruit and ½ pint of water to every 4lb.

Scald the plums, peel, cut into two and remove stones, peel, core and slice apples and pears. Place these with the sugar in layers in the preserving pan, add the water. Heat slowly to boiling point, cook gently, stirring constantly until the jam is smooth and thickens. Test in the usual way, pot and tie down at once.

Note.—To prevent marmalades and jams from catching, grease the bottom of the preserving pan lightly with fresh butter, or put in the pan two or three sterilised stone marbles or a silver coin (two-shilling piece).

BILBERRY JAM.

The bilberry, known in Scotland by the name of blaeberry and in some districts as the whortleberry, makes a good useful jam.

Proportions.—Equal quantities of fruit and of preserving sugar.

Wash the berries, which should be fully ripe or the jam is tasteless, drain well, put into the preserving pan and heat slowly. Add the sugar, dissolve and bring jam to boiling point. Boil gently, skim well and stir frequently. Test when it is done, pot, cover and tie down in the usual way.

Bilberry Jelly.—Equal quantities of fruit juice and of sugar. Proceed as for bramble jelly.

GREEN GRAPE AND ELDERBERRY JELLY.

This is an excellent way of using grape thinnings.

Proportions.—To each pint of green grape juice allow double the quantity of elderberry juice and 1lb. of preserving sugar to each pint of mixed juice.

Wipe the grapes, remove stalks, put into a preserving pan with just enough water to cover them and boil gently till soft, strain in the usual way for jellies. Gather the elderberries dry, remove stalks, put into an earthenware jar, and proceed as for damson jelly, stir and press the fruit from time to time to extract juice, then strain. Mix the fruit juices, boil for ten minutes, add the sugar and boil for twenty minutes or until the liquid "jells" when a little is poured on a cold plate. Skim while cooking if required.

Note.—Grape cuttings are often used alone for making jelly, which is suitable for serving with game and meat dishes.

CRAB APPLE JELLY.

Proportions.—6lb. of crab apples, 6 cloves, the juice and thinly peeled rind of 2 lemons. To each pound of fruit allow 1 pint of water and to each pint of fruit juice 1lb. of sugar.

Wash the fruit and with a silver knife cut each apple into two or three pieces without peeling or coring. Put the apples into the preserving pan, add the cloves and thinly cut lemon rind, cover with the water and cook slowly until the fruit is quite soft and broken. Strain through a jelly cloth, letting it drip all night. Add the necessary amount of sugar and the lemon juice to the fruit juice, let sugar dissolve, bring to boiling point and boil until the jelly sets when tested. Skim if necessary.

Note.—Later on in the season when cranberries begin to appear in the market their addition makes an excellent jelly. Allow 1lb. of cranberries to every pound of crab apples, adding them when the apples are half done.

ROWAN OR MOUNTAIN ASH JELLY.

Proportions as for jellies usually.

Use ripe berries, remove stalks, wash and put into the preserving pan with sufficient water to prevent them from burning, about ½ pint to every 2lb. of fruit. Simmer and stir constantly to extract the juice. When quite soft strain in the usual way; avoid squeezing the fruit. Measure the juice, heat the required amount of sugar, add it to the juice and boil quickly for about twenty minutes or until it sets when tested in the usual way. Proceed as for jams and jellies. This is often served with game or with mutton.

VEGETABLE MARROW JAM.

Proportions.—4lb. of marrow when peeled and with seeds removed, juice and thinly peeled rind of 2 lemons, 1½oz. of whole ginger, 4lb. of preserving sugar, pinch of cayenne, one wineglassful of brandy if liked.

Choose a fresh marrow of medium size, if old the preserve does not clear well. Wash, dry and peel the marrow, remove the seeds and cut into ½in. dice. Put the marrow and sugar in layers in a large basin, add the ginger bruised and tied loosely in a muslin bag with the lemon rind and leave for twenty-four hours. Put all into the preserving pan, add the cayenne and boil till the marrow is soft and transparent looking and the syrup is clear. Shortly before the jam is ready to be removed from the fire take out the muslin bag and at the last add the brandy. Pour into jars, cover and tie down.

TOMATO MARMALADE.

This can be made with either red or yellow tomatoes, the latter make the best marmalade.

Ingredients.—1 quart of ripe yellow tomatoes, 1 lemon, 2 oranges, 2lb. of preserving sugar.

Peel lemon and oranges thinly and without any pith, boil in a little water until tender, drain and cut into thin shreds. Blanch the tomatoes to remove the skins and cut into small pieces. Put the shredded orange and lemon rinds, tomatoes and sugar into the preserving pan, let sugar dissolve, bring to boiling point and boil until the marmalade is thick and the peel transparent. Test if done, pot and cover at once. This is an excellent way of using any superfluity of home-grown tomatoes.

S. E. N.

NOTES FROM CONTRIBUTORS

KAUFMANN S TULIP.

OF the tulip species straight from their native lands we have none more charming than Tulipa Kaufmanniana from Central Asia. There are, it is true, many wild tulips of more commanding presence and more gorgeous colouring, but none can surpass it in real loveliness. It has been aptly called the "water lily tulip" on account of its resemblance, when open, to a water lily, and the simile is quite an appropriate one. When the flowers open flat to the sun the blooms remind us of nothing so much as those of a charming nymphæa basking in the sunlight of summer. But the tulip long anticipates the summer days, and it is in reality one of the very earliest of all tulips. Its haste to give us its beauty before its sister flowers, sometimes leads to its undoing in some districts where the winters are wet and mild followed by sharp frosts in spring, which injure the foliage and weaken the growth so much that the bulbs dwindle away. But this can be avoided by planting the tulips where the sun does not reach them until about midday. It is, however, generally perfectly hardy. This gracious tulip, which is only about 6ins. high, is variable in its colouring, and several varieties are occasionally offered under distinct names. What is generally called the typical one has white and yellow blooms with the exterior striped with red. Some forms have a pretty zonation of red in the interior. A variety which finds favour with some is called Brilliant. It has glowing flowers of what is known as Turkish red. A charming one with white flowers and of very dwarf habit is named Gaiety. It is a great beauty, though, like the preceding and that which follows, much more expensive than the type. Then there is a pretty one called Primrose, which, as the name would suggest, is of a pleasing shade of primrose yellow. All these have wonderfully large flowers, charming in bud and still more delightful when fully expanded. They can be procured in autumn and planted in moderately heavy soil 2ins. deep, placing a little sand round the bulbs. The writer knows a garden where there is a fine group of nearly a hundred bulbs of this tulip with muscaris planted along with them, and very lovely does the combination look. But even a plant or two in the rock garden or border will give the greatest delight to all who will find space for Kaufmann's water lily tulip in their gardens.—S. ARNOTT.

PAPAVER PILOSUM.

WHILE the Iceland and Oriental poppies come in for a generous share of attention, this—a perennial, by the way—is hardly ever met with. In spite of this it is very showy with flowers that vary from deep orange to bright brick red, each petal having a white spot at the base. The leaves are pale green and densely clothed with fine hairs, a similar feature being noticeable on the flower-stems. The best way to procure plants is by saving seed, from which the plants come fairly readily. This seed is best sown where the plants are to grow, merely thinning them out to suitable distances apart when strong enough to see which are the best. In this way all difficulty of transplantation is avoided and so the plants grow vigorously right from the very start.—HAVELOCK.

CORRESPONDENCE

ACACIA MONILIFORMIS.

SIR,—I am sending you a cutting from a most lovely acacia growing in the gardens here at Bussaco. I believe it is Acacia moniliformis, but I should be much indebted to you if you would have this verified. And will it grow in England? and, if so, where can it be obtained? It is a glorious sight here—graceful and very beautiful both in habit of growth and flower. I understand it is a native of Argentina. Bussaco stands high on the northern Portuguese range, with a heavy fall of snow in winter. It now lies basking in a glorious sun, but never too hot for pleasant walking in the Bussaco Woods, as there is always a cool breeze from the mountains. I write from memory of many years back, but I think I remember this acacia in Lord Grey's Howick garden, Northumberland. If so, Lord Grey's acacia must be almost a forest tree compared to the big bush growing here. May I congratulate you on the recent issues of THE GARDEN, which I have sent to me here. Your paper has always, to my mind, been the *Times* of the gardening world.—H. E.

[As far as we could judge from the specimen sent, which was rather crushed on arrival, the plant was Acacia moniliformis. Like other acacias, we should not imagine that this species will be hardy in this country, as the whole genus prefers a warm clime and cannot endure frost when out of doors save in some localities.—ED.]

GERANIUMS AS WALL SHRUBS.

SIR,—I enclose a photograph showing the height of the geraniums which grow against the wall of my house and wonder if it would interest the many readers of THE GARDEN. Shown in the illustration are two plants of pink geraniums (the two largest bushes), while the smaller bush is that of the dark red double geranium.—G. WYNDHAM.

BEAUTIFUL WALL BUSHES OF PINK GERANIUMS.

THE PURPOSE OF WISLEY?

SIR,—Your Leader of June 28th is very interesting and should cause the Wisley Committee of the R.H.S. furiously to think. I confess that the trials of vegetables do not appeal to me much. The trials of species and varieties of flowers do, but not so much the kinds usually chosen by the Committee, such as salpiglossis, godetias and other annuals. Ryders', Carters' or any other trade list will give you the information with regard to oddments of that kidney. The information I want is quite different, and not of a kind obtainable as a rule from the tradesman, who has to dispose of wares of sorts and with different names. What I want to know is whether the nursery names are accurate or mere tales of Lucian, or dreams of Arabian Nights? I think the Committee might devise a method of certifying stocks of the nurserymen as being true to name, by means of some form of certificate to that effect given from time to time by a R.H.S. inspector. I suppose during the year some nine to twelve catalogues from different firms come to my house. What guarantee have I that campanula this and primula that are not really something quite different? The late Mr. Farrer's "The English Rock Garden," is full of references to catalogue inaccuracies. For instance: "Primula viscosa is offered in catalogues under almost any other name than its own"; and under Primula hirsuta: "However, though the arch-breeder of confusion in catalogues," etc. Then under saxifraga: "There is not as yet any finality in the family, which lies at present in a fearful welter of confusion, largely owing to its popularity in the garden, which has impelled nurserymen to go on perpetually issuing unauthorised and synonymous and false species, as well as multiplying varieties with a zeal only to be paralleled by botanists themselves."

I think many will agree that here at the Wisley Committee's hand is material calling to the stars for remedy, and I am sure that most members of the trade would give all possible assistance in their power to the Committee in search of a solution to this pressing problem. A somewhat similar problem was brought to the notice of the National Rose Society by myself at the Annual Meeting in 1923. The number of roses, all too much alike, in the championship classes at the 1922 show at Regent's Park drew my notice to the situation caused by this multiplication of new varieties. "Fanny Smith" comes up again as "Mary Jones," in the same box, with, a little farther down, "Lizzie Green," all the same rose, perhaps even cut from the same tree. But in a rose catalogue you will see the same roses, one issued to a confiding public in 1890, another in 1902, and the third in 1911. What a game! And every catalogue of plants is full—too sadly full—of duplicates and inaccuracies such as these. As a concrete example, I got from one nursery two plants, one labelled Primula Matthioli, the other P. atriculata. The first I have placed, but it is not a primula at all; it is really cortusa! There is no trace of P. atriculata in Farrer's book. What is this new addition to the family? I can only wonder!

I was shown at Perry's Plant Farm two lots of primulas in a frame, and the foreman pointed out to me the two Edinburgh labels: P. Wilsonii and P. glycosma. Short of seeing the bloom, they were the same; same leaf, same plant, same delicious scent. The problem I leave to you and Father Time to solve.

Supposing then the R.H.S. were to attempt a solution of this problem, one wonders how far the trade would go towards assisting the Society, and whether they would be willing to scrap inaccurate labels and to place varieties and species where they really belong. It would involve considerable labour doubtless, but it would give clients much more satisfaction to know the true names of plants in their gardens, and would give them a chance of being able to grow them successfully, through knowledge (easily obtained by reference to a reliable text book) of how to place them in the garden.

As regards the distribution of plants, those that are given out to the members as plants or seed are either shrubs or varieties and species no self-respecting owner of a small garden can grow—rampers like iberis of sorts, arabis and aubrietia. If one tolerates their presence, one only grows them because once, in a foolhardy moment of indecision, they were introduced and cannot be got rid of. By a happy chance, and I am sure a fluke, last year I got a plant of Primula glycosma. One can also obtain abundance of seed of cotoneasters, barberries, and other shrubs and shrublings. But what I would personally prefer are some of the wonderful treasures, described so vividly by the late Mr. R. Farrer and others, from the Roof of the World. Why cannot they distribute P. vincæflora and the other omphalogrammas, the saussureas, Gentiana Farreri, G. sino-ornata, etc,. Rheum Alexandræ, the new delphiniums and all the other delights which make your eyes glisten. They do not seem to have a soul above a shrub, and we do not only want shrubs in small gardens. Do all these treasures go solely to Edinburgh?

I am afraid I have been somewhat prolific but I think that the importance of the subject warrants it.—P. A. HENDLEY.

ROSE COLOURED VERONICAS.

SIR,—I should be delighted to learn something from Mr. H. S. Thompson concerning Veronica longifolia, V. spicata and allied forms, hybrids, etc. (see pages 538 and 574). I have been puzzled with garden names and forms of these for more years than I care to mention. I mentioned V. spicata rosea on page 538, but it is also in cultivation under the name of V. longifolia incarnata. The entire-leaved specimens of V. hybrida from the St. Vincent Rocks, Bristol, are surprising. I have a specimen collected there on August 20th, 1921, and every leaf is serrate-crenate. With regard to V. rosea Desf., I can give the celebrated J. Gay's description of a plant from Desfont's herbarium: "Herb smooth or very loosely and finely downy. Stems very crowded, herbaceous, woody at the base. Leaves oblong-linear, pinnatifidly five-lobed (not divided to the midrib). Racemes axillary, many-flowered. Pedicels equal to or exceeding the bracts, very smooth. Calyx likewise very smooth, four-partite, with the two upper segments one-third shorter. Fruit desirable." The plant is similar in habit to V. prostrata, but the flowering branches are more erect. Notwithstanding Gay's description, I find a considerable amount of long falcate white hairs on both sides of the leaves, on the stems and rachis, and the sepals are ciliate or thinly hairy. I would also describe the leaves as oblanceolate, cuneate, with triangular, spreading teeth, varying from one to five on a leaf. Though comparable to V. prostrata, the branches are more erect and the leaves entirely different. It would make a desirable plant for the rock garden if hardy. The species is a native of various parts of Algiers, including the south and west of the province of Oran.—HORTULANUS.

FORTHCOMING EVENTS.

September 17th.—North of England Horticultural Society's Exhibition (three days).

September 23rd.—Royal Horticultural Society's Autumn Exhibition at Holland Park Hall (three days).

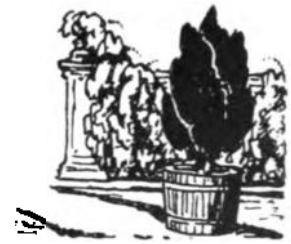
SIMPLE GARDENING



TEMPERATURES OF GLASSHOUSES.

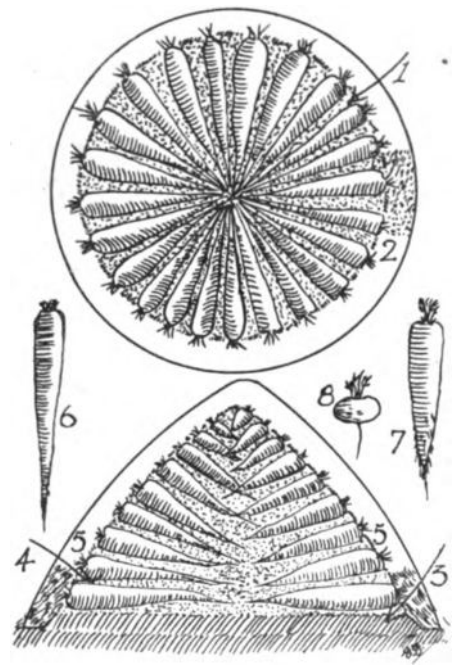
IT does not seem very long since we were concerned with keeping our plants under glass safe from late frosts. Now, our minds dwell on the same matter: how to keep them safe from early frosts and excessive moisture. In late winter and early spring young shoots were growing and we had to bear in mind the fact that a check to their growth would be very harmful. Now, we require some artificial heat—in certain cases—to help forward the ripening of the shoots made during the summer and also fruits such as grapes, late melons and peaches. This may be done with due regard to economy. Every morning, when the sun gains power, the ventilators may be opened a little wider to admit the warmed air and the fires may be put out or banked with damp ashes to keep them just alight. In the afternoon, about one hour before sunset, the ventilators should be finally adjusted for the night, the flue dampers drawn out and the lower doors, through which the ashes are drawn, opened wide to ensure the fire burning up brightly. Thus the heat in the pipes will be just right when that from the sun is waning in the house or houses. These hints apply where there are growing plants. But there are houses in which the wood of plants, especially fruit trees, is ripening and here very free ventilation night and day will be beneficial.

DRYING AND STORING ONIONS.

Last year, owing to the very dry summer, there was little difficulty in getting onions harvested in first-rate condition; the bulbs were small to medium in size and all such, when perfectly ripe, keep well in suitable stores. This year, owing to quite different weather conditions, the bulbs are large and, in many gardens, still growing. Of course, every effort should be made to get these big bulbs ripened sufficiently to ensure sound keeping during the winter and early spring months. By the middle of October, at the latest, all bulbs should be cleared off the ground; the harvesting generally begins at the end of August. The small bulbs, those resultant from spring-sown seeds in the open border, do not require any attention beyond that of lifting and drying for a short time on the ground. The larger specimens need assistance so that they will mature and not start growing again. To this end it is a good plan to remove the soil around the base of each with the aid of a pointed stick and the fingers, almost baring the roots themselves. Then those that show a tendency to make new growth should be lifted almost out of the soil and left for a few days prior to entire lifting. Place all in single layers with the roots towards the south. The best storeroom is one that is cool, dry and well ventilated. Store all large bulbs in single layers, on their sides or roots uppermost.

LIFTING AND STORING VEGETABLE ROOTS.

Leaving out potatoes, we may expect a heavy yield of vegetable roots this autumn. They are worth taking great care of and should be treated as shown in the accompanying sketches. Cool, dry sheds or dry positions in the open are suitable; hot sheds are not. Dry earth,



sand or ashes should be used to pack the roots in, and exclude light and air. Both long and round-shaped clamps will answer. No. 1 shows the basal layer of roots with sand between them; these may be carrots or beet. Smaller roots are packed near the top, and an outside layer of sand or ashes (No. 2) completes the work, with a wisp of straw at the top to ensure ventilation. The long clamp is also on a dry base, No. 3. No. 4, sand. Nos. 5, 5, outside covering of sand, ashes or soil. No. 6, shows a prepared carrot, and Nos. 7 and 8, prepared beets. Ease up the roots with a fork; cut off the tops of carrots and turnips and twist off those of beet. Do not wash the roots.

FRUIT TREES IN POTS.

Growing fruit trees in pots is very interesting work. Artificial heat is not necessary to successful cultivation, but the glass structure should be high enough to ensure several feet of air space above the branches. When the trees are at rest, as they will be soon, they should be placed close together on a bed of ashes, the branches fully exposed but the pots well encased in dry leaves or litter to prevent frost reaching the roots. This is the most important point. Before any protecting material is used, make quite sure that the soil in the pots is well moistened through. Perhaps some of the specimens will need re-potting, if so, put them by themselves, take the measurement of the pots and provide others quite 2ins. larger; 3ins. or so would be better. Also provide the new compost, which should be, mainly, fibrous turf cut and stacked about six months ago. A small quantity of old mortar rubble will be beneficial, especially in the case of stone fruits, and bonemeal can be added at the time of potting. When this work is done be sure that the drainage is sound and that the new soil is well firmed. If the weather is dry apply water; if wet, the exposure to rains will be sufficient. Usually the leaves fall at an early date and the pruning required may be done forthwith. Apples, pears, peaches, nectarines, cherries, plums and vines are the principal kinds to grow in pots.

SPRING-FLOWERING PLANTS.

Some of these are finally planted in the autumn while others are left till early spring. In either case the plants require attention now. It will not answer to leave overcrowded in small beds those that must wait until spring, as if so left they will not be as good in spring as they are now. Do not wait until the year is passing out before transplanting the young seedlings, but do the work now. The soil is warm, works well and is in just the right condition to ensure a little more growth and the establishment of the plants before real winter weather comes. I am particularly referring to such plants as wallflowers, giant-flowered daisies, polyanthuses and primroses, myosotis, etc. These are all small-growing plants except the first named and do not take up much room in the nursery quarters, but great numbers should be grown where several large borders are to be filled. Then there are the instances where the final planting can be done this autumn, and where the soils are light or well drained it is the most satisfactory way of dealing with the plants. Usually the beds are filled with summer-flowering plants and the soil will need enriching. If bulbs are also used, some well rotted leaf-soil, in addition to rotted manures, should be obtained and stored in readiness for use directly the present occupants are cleared from the soil. GEORGE GARNER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Lettuce.—Every effort should be made to keep up a supply of lettuce, because at this season there is a possibility of running short. Another sowing of hardy kinds can be made, both in frames and the open ground, while from the sowings made in late July and early August the seedlings should be planted out directly they are large enough.

Hoeing.—During the autumn months weeds make considerable headway unless they are kept down with the hoe. This season has been very wet and dull, which has entailed a lot of extra labour to keep the ground clean; on several occasions it was necessary to hand-weed the plots, and remove the weeds to the rubbish heap. Let us hope the autumn will afford a chance to employ the hoe freely. All decayed leaves should be removed from the winter greens and Brussels sprouts usually need attention more frequently, or the buttons will be poor in quality owing to lack of air passing through the plants.

FRUITS UNDER GLASS.

Peaches and Nectarines.—For the most part the fruit has been gathered, and on no account must the trees be neglected during the next few weeks. The ventilators should be opened to their fullest extent, both day and night. The foliage may be kept clean by an occasional use of the hose pipe, and where necessary give a spraying with insecticide. The most important factor, however, is a moist border, if this becomes dry at this period, next season's crop will suffer. Old trees and those that have not made much growth will benefit by liberal supplies of weak liquid manure. Remove any wood not required, so that light and air can thoroughly ripen the shoots that will bear fruit next year.

THE FLOWER GARDEN.

Rose Cuttings.—Nearly all the stronger growing roses will succeed on their own roots, and for planting in a semi-wild position the rambler section are much better on their own roots because the sucker nuisance is entirely removed. Select fairly mature wood for cuttings, which should be set in pots of sandy soil and given the protection of a cold frame. Early next month a batch could be inserted in the open ground, placing the cuttings in lines 1ft. apart. Here they will remain for twelve or fourteen months.

Pentstemons.—Owing to the damp season there are now plenty of young shoots suitable for cuttings, and having ascertained the quantity required they should be inserted in sandy soil placed either in boxes or a cold frame; the latter being preferable where a large number of plants are needed. P. Southgate Gem is excellent for borders if grown in large patches.

THE HARDY FRUIT GARDEN.

Morello Cherries.—The best time to prune these trees is immediately the fruit is gathered, and such work differs from the pruning of the dessert varieties. It is similar to the pruning of peach trees, the old wood that has borne fruit is cut out unless it is required to cover the wall. Where due attention was given to disbudding earlier in the year, the wall space will be covered with young shoots, and now these must be so distributed as to prevent overcrowding. It should be borne in mind that the current season's growth will bear fruit next year. If the soil has become exhausted it ought to be removed so that the roots are exposed, and then replaced with good quality loam to which is added a liberal sprinkling of mortar rubble.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Cauliflowers.—Plants raised from seed sown early in August should be set out 6ins. apart in firm, but not over-rich soil in a cold frame. The plants should be lifted from the seed bed carefully and with as much soil clinging to the roots as possible, then planted in the frame with a trowel. It may be advisable to shade from very bright sunshine for a few days, but otherwise keep the plants hardy.

Parsley.—Young plants set out in June should be a good size now, and those who require to keep up a supply throughout the winter should have a quantity of these plants lifted and replanted in a cold frame. Established plants in the open such as those raised from seed sown in July can be protected by having frame lights placed above them, to keep off the rain and snow. This biennial plant is not quite hardy, in fact the leaf-stalks in severe weather when unprotected appear to suffer first.

Tomatoes.—The plants have grown well and produced good clean crops, and have been free from the dreaded white fly. As soon as the plants are somewhat spent the remaining tomatoes should be gathered and placed on a shelf or hung from the wires in some of the other houses to ripen. The plants and the soil should then be cleared from the house, then the woodwork and glass thoroughly scrubbed and washed before any other plants are housed therein.

THE FLOWER GARDEN.

Lilium candidum.—This fine lily when in flower is much to be admired and more so when it is associated with old-fashioned border flowers. Bulbs when once established and doing well should not be dug up except when they get overcrowded. When planting fresh bulbs in beds or borders, it is advisable—except in light soils—to take out good sized holes at each station and fill them with a mixture of fresh turfy loam and old lime. This should be made firm in each hole, then sprinkle sand on the surface and dust the bulbs with sulphur before setting them on the sand; finish by covering the bulbs to the depth of 4ins. with the soil mixture.

Violets.—Plants need the protection of a frame in which to expand their blooms throughout the winter months. Preparation, therefore, should be made now for having the plants transferred to the frame. Chopped loam and leaf-mould in equal proportions and well mixed is a suitable compost to place in the frame. The plants should be well moistened at the roots previous to being lifted so that plenty of soil clings to the roots of each plant raised. The plants should be set free of each other and all within a few inches from the glass. Another good watering should be given to settle the plants in the fresh soil; but the frame lights need not be put on unless frost threatens. Plenty of air should be given on all favourable occasions, and a covering placed over the frame-lights in severe weather.

THE HARDY FRUIT GARDEN.

Apples.—Continue to gather apples and pears on all fine days when the fruits are dry, and as the different kinds approach the ripening stages. Handle the fruits carefully, then place and space them out on the shelves in the fruit room. Old and worn-out trees should be sawn over and the roots dug up; the branches and the roots should be taken to the back yard and burned.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Annuals in Pots.—Seed of hardy and half-hardy annuals which are now so popular for conservatory and greenhouse, should be sown about the middle of September. Among the most popular and useful sorts for sowing at this time are schizanthuses, of which there are a number of fine strains. Here I would suggest that more attention should be given to S. retusus and its varieties; it is very beautiful and distinct from the more commonly grown varieties, its stiffer, upright sprays of flowers being very useful for cutting. Clarkias and godetias in many fine varieties are also prime favourites. Godetia Lavender should be more generally grown as it is a beautiful colour and well grown plants make quite large bushes. Lychnis Coeli-rosa—more generally known as Viscaria—of which there are several varieties, is very graceful and remains in flower for a long time. Mignonette, of course, should not be omitted, but requires special care to grow it really well. Nemesias in many beautiful varieties are specially useful for small pots. Calendula officinalis, especially the variety Orange King, should be more generally grown, as its brilliant flowers are very useful for decorative work, and for this reason it has now become a popular market plant. Other useful species and varieties that may be sown at this time are alonsoas, ageratums, Collinsia bicolor, very quaint and charming, also the pure white C. candidissima. Larkspurs, the tall branching stock-flowered varieties being specially useful. The dwarf varieties of Phlox Drummondii are also very charming. As will be seen from the foregoing list there is plenty of variety to choose from, and they should all succeed under the same methods of cultivation. Seed may be sown any time during the later half of September or even the beginning of October, sowing the seeds according to requirements either in pots, pans or shallow seed boxes, standing them in cold frames and keeping them shaded until germination takes place. The compost in the seed boxes should be made moderately firm, sowing the seeds very thinly, as overcrowding means weak plants, and danger from damping off; if damping off starts, the remaining plants must be at once transferred to fresh compost. In any case, the young seedlings when fit to handle should be pricked off into pots or boxes, afterwards when large enough they should be potted off singly into small pots, or several in a pot, according to the class of plants; such things as schizanthuses being best grown singly, while more slender-growing plants, such as lychnis and collinsia, may have from three to six plants in a 48-sized pot, in which size they can be flowered. Most of them can be wintered in sixties or 48-sized pots, potting them on into their flowering sizes early in the New Year. They can be wintered in cold frames, but a cool, airy greenhouse or low heated pit affords the ideal cultural conditions. In such structures they can be kept well up to the roof glass and, what is of utmost importance, ventilation can be more readily given on every favourable occasion. Success depends almost entirely on cool, airy conditions and, of course, careful watering at all times. One must always bear in mind the fact that all the plants in question are more or less hardy, and the great aim throughout their cultivation should be to maintain a compact sturdy habit of growth. This I may say is very difficult in the immediate neighbourhood of London and other large towns, where winter light is too often at a minimum. Under such adverse conditions it is really best to defer sowing until early in the New Year.

ANSWERS TO CORRESPONDENTS

THE FLOWER GARDEN.

Lavender Attacked (S. A.).—The plant is attacked by the fungus Phonia lavandulæ, which causes the disease known to lavender growers as "shag." The fungus is common, but it seldom causes serious damage, at any rate in small gardens. Diseased portions should be cut clean out and burned to prevent spread of the spores and the plants encouraged to make new growth.

TREES AND SHRUBS

Viburnum Carlesii (S. A.).—There is no sign of fungus on the leaves enclosed. The spots look more like burns, as if there had been acid fumes in the atmosphere washed on by rain, or it may be the work of an insect which has disappeared. Do not remove the leaves. Cuttings inserted now in sandy soil will root under a cloche or in a cold frame if kept close.

Planting an Ayrshire Garden (M. S.).—Flowering shrubs likely to succeed include Kerria japonica fl. pl., Philadelphus microphyllus, P. Lemoinei erectus, P. Virginal and P. Voie Lactee, Spartium junceum, Cytisus albus, C. scoparius and var. Andreanus, Genista hispanica, Potentilla fruticosa, Hypericum calycinum, Tamarix pentandra, T. tetrandra, Diervillas Eva Rathke, Abel Carrière and candida, Spiræa bracteata, S. japonica and var. Anthony Waterer, S. Margaritæ and S. Menziesii triumphans, the double gorse and Rubus ulmifolius bellidiflorus. Small specimen trees suitable for the lawn would be Laburnum alpinum, Prunus Avium fl. pl., double scarlet thorn, Cratægus Crus-galli, C. cordata and Pyrus aucuparia. Without seeing the actual site it is not easy to suggest a lay-out for a sloping bank of unequal outline. It depends on the position and its proximity to the house whether formal low brick terrace walls and paths would be preferable to undulating walks and rough crevice walls planted with alpine and rock plants with dwarf shrubs on the borders or wide ledges. Suitable shrubs might include Cytisus kewensis, C. purpureus, C. Beanii, Genista tinctoria fl. pl., G. procumbens, Cotoneaster microphylla, Daphne Blagayana, helianthemums, lavenders, callunas and ericas if there is no lime in the soil, also a few dwarf conifers.

THE GREENHOUSE.

Hardy and Half-hardy Plants for Winter-flowering (E. F. B.).—In addition to the kinds of plants you mention, the following would serve your purpose. Antirrhinum Nelrose, carnations, clarkias, godetias, Dielytra spectabilis, Spiræa japonica, marguerites, winter-flowering wallflowers, kalmias, azaleas, hydrangeas, Spanish and English irises. However, it would be necessary, at this late date, to procure forward plants of some, such as the wallflowers and carnations and plants established in pots, such as deutzias, kalmias, hydrangeas, azaleas, etc., stocks, Beauty of Nice in several colours, Empress Elizabeth, Brompton. Much would depend upon the weather, as without artificial heat some plants may fail in severe weather.

FRUITS UNDER GLASS.

Grapes Mildewed (Mrs. T., Saxmundham).—The berries are badly mildewed. Over-dryness at the roots, cold draughts and too much moisture, respectively, will cause mildew In the case under notice it is probably the latter this year. Flowers of sulphur dusted on the berries and leaves and afterwards syringed off with clean water will lessen the amount of mildew, but in any case the berries are spoilt for dessert purposes. Abol will destroy the mildew, but it also destroys the "bloom" on the berries. However, prevention is better than cure.

THE HARDY FRUIT GARDEN.

Strawberries and Spanish Irises (Miss N. W.).—The strawberry plants appear to be very old ones, judging from the number of side slips and crowns. They are in a bad state and not worth retaining. Destroy all of them and plant young ones in well dug ground enriched with rotted manure. Apply a dressing of soot first, enough to darken the soil, before planting. The Spanish irises may be lifted and re-planted forthwith, but not lifted and dried off. It is not advisable to disturb the roots of these irises too often, as new roots form before the old stalks have faded. A loose, sandy soil, porous, and well enriched with rotted manure, is an ideal one.

Gumming of Peach Clara Mercy (S. A.).—Nothing can be done to stop the gumming, and, unless very bad, the trees, as a rule, do not suffer. If crowded, thin the young shoots, removing the weakest, but do not shorten them.

Pears Cracking (J. de H.).—The pears sent for examination are badly cracked, the result of pear scab. This fungus also attacks apples and is more prevalent during a wet than a dry summer. The disease first appears on the leaves, and these should be syringed with Bordeaux mixture directly the dark brown spots show earlier in the season to prevent the spread of the disease to the fruits. When the season is a wet one, like the present, and the skin becomes contracted through disease, a sudden flow of sap from time to time causes wholesale cracking. If the trees are surface dressed with rotted manure and fibrous loam, a peck of lime per tree would be beneficial if applied in November.

VEGETABLES UNDER GLASS

Tomato Fruits not Colouring (A. M. R., Glos.).—Potash is necessary in the cultivation of tomatoes and, although wood ashes have been added to the compost, often these lose much of their strength through exposure and contact with moisture. The plants require heat but with free ventilation; a close atmosphere, or sudden exposure to a hot sun will also mar perfect colouring. In future mix the compost at an early date in the year. Good fibrous loam, basic slag or superphosphate, 6oz. per bushel of each. Also, if procurable, a 6in. potful of fowl manure. When the fruits have set on three trusses scatter 1oz. of nitrate of potash on one square yard of ground and wash it in with clear water. Two applications will be sufficient.

MISCELLANEOUS.

Novelties in Hardy Perennials (F. B., France).—If one had an idea of your fancy or taste, it would be easier to pick out what would be considered the best twelve. However, the undermentioned are excellent new varieties of their types: Chrysanthemum maximum Rentpayer (3ft.) and C. m. Mayfield Giant (5ft.) are the most up-to-date; other choice plants are Aster Amellus King George, Campanula persicifolia Telham Beauty (the largest, but more than five years old), Helenium Crimson Beauty, and Verbascum Amber Gem (the newest of this type). The above are obtainable from Messrs. Barr and Sons, King Street, Covent Garden, London. Iris Lord Lambourne, Iris W. C. Terry, Aster Snowdrift and Coreopsis grandiflora Perry's variety are offered by Mr. Amos Perry, Hardy Plant Farm, Enfield, Middlesex. Delphinium Sir Douglas Haig and Delphinium Millicent Blackmore are listed by Messrs. Blackmore and Langdon, Bath. Messrs. Waterer, Sons and Crisp, Limited, The Nurseries, Twyford, offer Lupinus polyphyllus Sunshine (golden yellow) and Campanula R. B. Loder (semi-double, pale blue, 6–8ins. high). Older but good are Verbascum Miss Willmott (white) and V. Caledonia (sulphur, shaded lake). The above are four more than the desired number, but the notes to some of them will give an opportunity for selection. Messrs. John Forbes, Limited, Hawick, Scotland, offer the last two verbascums.

Oriental Poppy Malformed (D. M. Y., S. Devon).—Non-fertilisation of the flowers is the cause of the peculiar formation. Instead of seed pods forming the flower would decay. Good cultivation is the remedy in the future. The plants require a deeply tilled, good rooting medium and, of course, a sunny position, with plenty of room for each specimen to fully develop. You cannot do more than this for the plants. The exudation has prevented fertilisation.

Names of Plants.—J. F. N.—Polygonum aviculare, "Knotweed." This plant is an annual and if prevented from seeding may soon be exterminated.

RULES FOR THE ROSE COMPETITION

A list of six (only) hybrid tea roses to be sent in in order of preference on a separate sheet of paper, with name and address of the sender clearly written on the top. NO ALTERNATIVES WILL BE ALLOWED, but readers may send in any number of lists.

Lists must reach this office not later than Saturday, September 20th (after that date no lists will be accepted) and must be accompanied by a coupon, to be found on page ii of this issue, and also in the issues of August 23rd and 30th, and September 6th.

The popular vote will be final, and no correspondence will be entered into over this competition.

Envelopes must be marked COMPETITION and addressed to THE GARDEN, 20, Tavistock Street, Covent Garden, W.C.2.

The Editor will not be held responsible for letters missing in the post.

The First Prize will be an order for £3 on any advertiser to be found in the pages of THE GARDEN.

The Second Prize will be an order for £2 on any advertiser to be found in the pages of THE GARDEN.

The Third Prize will be a book, or books, from the *Country Life* Library to the value of £1.

The result will be announced in THE GARDEN in the issue of October 11th.

The Editor's decision on all points will be final and binding.

See THE GARDEN, *August 23rd, page 578.*

THE GARDEN

ORCHARD GARDEN WOODLAND

Vol. LXXXVIII.—No. 2757 Saturday, September 20th, 1924 Price THREEPENCE

The Kelway Colour Border

The formation of actual scenes of beauty with living subjects abounding in interest individually would seem to be a pleasant and worthy amusement, and one as full of dignity as the portrayal of such scenes on paper or canvas.

The late Dean Hole truthfully wrote in *Our Gardens*: "There has been no introduction which has had such happy and universal influence in extending and increasing the enjoyment of a garden as the HERBACEOUS BORDER." One of the first remarks of one's hostess in the country nowadays is, "Would you care to see my new Herbaceous Border?"—or "my new KELWAY Border?" Send dimensions of space to be filled, and the effect required, stating aspect and soil, and asking any questions.

WRITE NOW to the inventors of Colour Borders:

BIRDS IN THE GARDEN

A FRIEND of mine was complaining bitterly to me to-day that the birds have never been so troublesome in his garden as this year. He is a great raiser of fruit, and he tells me that in order to save nearly every variety of fruit he has had to net the trees or bushes thoroughly. He was exceedingly bitter and venomous against the feathered world in general, not so much for eating the fruit, but for wanton destruction. He did not object to them pecking at a pear if they would finish it and leave the others alone, but they were quite indiscriminate and thoughtless; he likened them to a fox in a hen roost which delights in killing far more than he can ever eat.

Now, I am neither an ornithologist nor an entomologist. I like seeing birds flying about and hearing them singing. I always consider them the world's optimists. Most insects, on the other hand, leave me cold, and a few make me hot. I read all the numerous attacks and defences in the papers on starlings and rooks and am left little the wiser. Many claim, no doubt with reason, that in the majority of cases the bird pecks at the fruit or bud in pursuit of insects. Nevertheless, there is no gainsaying the fact that in the course of this pursuit they do more damage than the insect. A point which is of interest and which has never been properly answered is the problem of the increase of bird life. Do birds which frequent gardens increase at the same or a greater ratio than the area of ground transformed into gardens? I cannot believe that prior to the present popularity of gardening and the increase in the area of ground given over to gardens there was such a plethora of blue tits which, along with the bullfinch do more damage in a garden than any other birds. I should hazard a guess that these two marauders have increased beyond all necessary proportions, and yet misguided people attract more and still more tits by feeding them in the winter with coconut. I have watched blue tits in quantity sitting on a rhododendron bush stolidly and with the greatest determination attacking and destroying flower-bud after flower-bud. This seems to me to be a useless proceeding, for there is certainly no insect which damages the flower-buds of rhododendrons. I cannot think that rhododendrons are palatable, for they are poisonous, so I can only suppose that it is mischief, a trait which should be stopped at all costs. If it was for food there would be some excuse. That is one case of which I have personal knowledge, but owing to this knowledge I am suspicious of the work of birds in general in the garden.

Another side to the question is that of prior claim. If birds can prove that their ancestors lived on the spot before ever a garden was thought of, then they surely have a right of domicile, but having travelled in many parts of the world I can safely say that neither in New Zealand, Australia, Japan, India nor America have I ever seen such a plethora of bird life in gardens as in this country, and I believe that our crops suffer in consequence.

I have another friend who is a fanatic on the question of bird protection. He refuses to hear one argument against them and if cornered has one unanswerable retort, that he infinitely prefers one bird to a hundred flowers or fruits. On the whole I think that gardeners are more amenable and far more long suffering.

I am far from advocating the destruction of birds in the garden, but even the most ornamental can become too common. A bird of paradise is an admirable bit of decoration, but I can imagine that if you saw a hundred a day year in and year out you might become tired of them, while I have heard of a case of a man emigrating owing to the chorus of nightingales which kept him awake night after night. On the other hand, I think that birds are too much encouraged to frequent gardens by winter feeding, leaving fruit uncovered and so on, which seems to me to be an unnecessary inducement to birds to stay instead of moving on elsewhere. After all, a garden is a place in which to grow flowers, vegetables and fruit. It should not and it need not be an aviary. E. H. M. C.

NEW ZEALAND PLANTS FOR THE BRITISH ISLES.—IV.

VEGETABLES FOR AUTUMN ATTENTION.

REPORT OF THE AUTUMN ROSE SHOW.

Digitized by Google

DELPHINIUMS: THE KING OF BORDER PLANTS

THESE PLANTS ARE NOW RECOGNISED AS INDISPENSABLE TO THE HARDY BORDER, GIVING AS THEY DO A CHARMING COLOUR EFFECT TO THE WHOLE SCHEME. THEY ARE, HOWEVER, SELDOM UTILISED TO THE BEST ADVANTAGE, AND THE FOLLOWING CULTURAL HINTS WILL ASSIST MANY TO OBTAIN BETTER RESULTS.

TRULY these are noble plants, kings of the hardy plant border, towering in splendour above all their rivals and supplying the gardener with quite indispensable material for the embellishment of the garden. Especially are delphiniums valuable in providing colours unobtainable from any other plant; giving as they do all shades of blue, from the palest sky blue to the deepest ultramarine, and among the newer varieties shades of lilac-mauve, lavender and rose to the richest violet and purple.

Seeing they are so important in all hardy plant schemes and also that they are seldom seen at their best, these few cultural hints are given to assist readers to a greater success in their culture and thereby to further increase the popularity of these glorious plants.

Delphiniums, as most other plants in the border, give the best effect when planted in bold groups of separate varieties, say three, five or seven to a group, according to the size of the border, allowing a space of 2ft. 6ins. between the plants. Advantage should be taken of the variation in height as well as colour, not forgetting those very short and useful Belladonna varieties for the foreground.

CULTURE FROM SEED.

Seed should be sown as soon as gathered, usually towards the end of August, in shallow drills an inch deep in the open ground, or in boxes. If sown in the open great care must be taken that the young plants are not devoured by slugs as soon as the seed germinates. For this reason boxes are the most satisfactory as they can be more easily watched, and the slugs more easily trapped. The boxes should be about 2½ins. deep. Make the soil, which should be of medium texture, fairly firm. Sow the seeds in shallow drills and place in a cool house or frame. When germination has taken place they should be put into a cold frame where they will require very little attention until spring opens and the seedlings begin to make new leaves. It should be remembered that the seedlings, however small, will most probably lose all their leaves during the winter months, leaving a small "crown" in the seedbox which springs into growth on the arrival of a few warm days in early spring. Plenty of air should be given when the new leaves appear, to keep the plants sturdy and hard, and at the end of April they may be planted in the open ground. The soil which is to receive these seedlings should have been previously prepared by being deeply dug and well manured. Some of them will give small spikes of flower during July, August and September, and will give really fine spikes the following season.

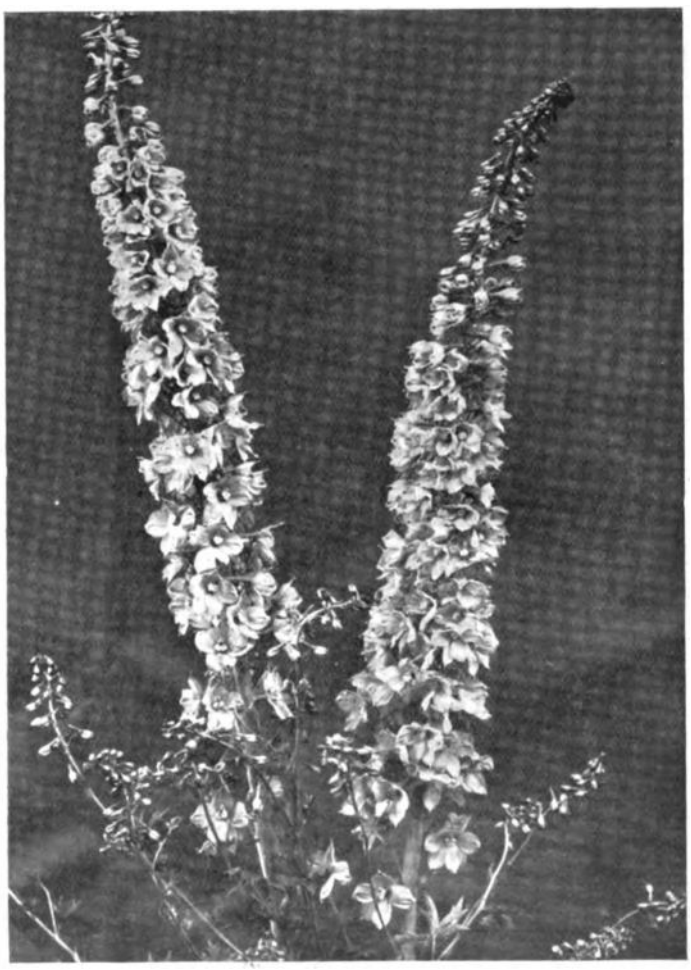
PROPAGATION.

There are two ways of doing this. Firstly, by division of the clumps which can be done either in early autumn (end of August or early September), or in spring (end of March or early April). On no account should they be cut about during the months October to March if growing in cold or heavy soils. In dividing old clumps the best tool is a strong and sharp knife. The work should be carefully done, retaining for each division two or three eyes or young shoots, and as much root as possible.

Secondly, by cuttings of the young shoots in early spring. These should be taken when about 3ins. long, exercising care to get the heel of the cutting by making the incision close to the root stock. These cuttings will root readily if inserted in sandy soil and placed in a cold frame, kept close and shaded until rooted, when they can be planted in the open ground. The year after planting they will make fine flowering crowns.

Delphiniums, more than any other hardy plants, generously repay first-class cultivation. They are gross feeders and delight in a deep, rich, loamy soil with which has been incorporated plenty of decayed cow manure. If possible, the soil should be worked to a depth of 2½ft. to 3ft., but where the soil is too shallow to allow this, holes can be dug out and a good layer of manure placed in the bottom and the soil replaced before planting. The eyes or crowns should be buried to a depth of about 2ins. Planting may be done either early autumn (early September) or spring (March or early April). Late autumn planting is a frequent cause of failure, especially in wet and cold soils. Neither should they be planted in February, when the soil is invariably very wet and cold. Delphiniums should not be expected to make a full display the first season, as it takes a year to get them well established, however large and strong the plants may be. An ideal plant for placing in the border is one which has a bunch of fibrous roots and two or three eyes. A plant possessing just a few large, thick roots is an old one and will take considerably longer to establish, even if it possesses a dozen eyes.

A question often asked is "How often should delphiniums be moved and divided?" It is safe to say they should not be left in the same place for longer than five or six years and then only if they have been well supplied with manure and are in good health. These old plants will make many more shoots than is necessary to furnish the plant, and these should be thinned out, when about 6ins. high, leaving an average of six or seven; if more be retained they will become crowded. A good mulching of decayed manure is of good assistance to these old plants and should be applied in April or May after growth has commenced. Water should also be given them freely in dry weather, remembering that it is the extremities of the root that need it, and that these not only extend 18ins. to 2ft. from the centre of the plant, but also are probably 2ft. in depth, so



THE BEAUTIFUL AZURE DELPHINIUM BLUE BOY. Characteristic of the single-flowered varieties.

Digitized by Google

that a mere surface watering is practically useless. An occasional soaking of liquid manure will be of great help and the plants will respond very quickly to its application.

Delphiniums being such tall growers, staking is a very important and necessary operation. It should be done before there is any chance of damage from winds, when the plants are about a foot high. Good stout canes of various lengths are most suitable and three to each well grown clump should be used, being placed triangularly and not too close to the plant, leaving sufficient room for the spikes to sway a little during rough winds, as they will be less likely to break than if each spike is tied separately to a stick.

Many enquiries are made as to the best method of preventing slugs from eating the young crowns during the winter and early spring months. The best known method is to clear away all soil from the crowns and cover them with new cinder ashes to which a good dressing of soot has been added. Slugs will not attempt to burrow into the ashes and the young shoots will push their way through, being quite free from attack.

STATELY SEEDLING DELPHINIUMS IN ALL SHADES OF BLUE, INDIGO AND PURPLE.

A considerable diversity of opinion exists as to the ideal form of spike at which raisers should aim. "Millicent Blackmore" is, however, generally acclaimed to be the perfect delphinium, with its large circular semi-double flowers, symmetrically placed on a beautifully tapering spike, with no suspicion of crowding, and each flower standing well out on a stiff and almost horizontal stem. Other varieties which approximate to this form are:—The Shah, A.M.R.H.S, (1924), Lavanda, George Cochrane, Edward Bromet, Purple King and The Alake

Another distinct type is that represented by such varieties as Lord Lansdowne, Mrs. Townley Parker, Blue Boy, etc. The flowers in these varieties are quite single and conform to that of the true larkspur. It is in this class we get the best pure blues, and as delphiniums are valued so much for giving a range of real blue flowers, this group is indispensable. Let us hope that the time is not far distant when great improvements will be made in these real blues.

The undermentioned are a few really good standard varieties of robust constitution, from which all amateurs wishing to introduce delphiniums into their gardens could safely make an excellent selection:

Blue Boy, Colonel Sir Wyndham Murray, Lavanda, Lord Lansdowne, Lord Derby, Millicent Blackmore, Mrs. A. J. Watson, Mrs. Shirley, Mrs. Colin McIver, Mrs. Townley Parker, Queen Mary, Queen of Bath, Robert Cox, Rev. E. Lascelles, Sir D. Haig, The Alake, Willy O'Breen, Walter T. Ware, and in the Belladonna section: Capri, Lamartine, J. S. Brunton, Mrs. Thomson and Musis Sacrum.

DECIDUOUS BARBERRIES with BEAUTIFUL FRUITS

FOR COLOUR EFFECT IN AUTUMN AND GENERAL ORNAMENTAL PURPOSES IN THE SHRUBBERY, THERE IS NO FAMILY OF HARDY SHRUBS WHICH IS MORE PROMISING THAN THE BARBERRIES.

AMONG the ornamental shrubs of our gardens the barberries represent a group of the very first rank. During a long stay in the Arnold Arboretum I had a splendid opportunity of forming a good idea of the special value of a number of species. In addition, I took some photographs of fruit-bearing twigs, and I wish to call attention to some of the hardiest and best-growing species.

One of the best undoubtedly is the Japanese Berberis Thunbergii, a species which became very popular in North-eastern America shortly after its introduction towards the end of the last century. It has not been found in China. It is well marked by its purplish brown, deeply furrowed branchlets, and forms broad and dense bushes, measuring up to more than 6ft. in height. The compact habit makes it very suitable for small dense hedges, but it is seen at its best as a group of a few plants on a lawn. The flowers are small and of a pale yellow with reddish sepals. They are not as showy as the handsome bright red berries, which are single or in pairs. At the same time of the year the leaves become brilliant red, the whole plant often looking like a fire-bush. The species does not do as well in England as in North-eastern America and on the European continent. Nevertheless, it certainly is one of the best deciduous barberries for our parks and gardens. There are several varieties, as var. minor (var. Dawsoni) and var. pluriflora. The first has a more compact habit, while the inflorescences of the last bear from three to five flowers. Most of the plants in our gardens of the so-called var. pluriflora belong, however, to B. ottawensis, a hybrid between B. Thunbergii and B. vulgaris. Under the name B. Maximowiczii, a form of B. Thunbergii may be found which hardly differs from the type except by the leaves being almost greenish, not glaucous beneath.

Another species of which the leaves are beautifully coloured in the autumn and which usually bears the fruits single or in pairs is the Chinese B. diaphana. It is a native of the northern and central provinces of eastern China, and forms rather compact and dense bushes probably not over 5ft. in height. The branchlets are yellowish brown, the leaves larger

Digitized by Google

than those of Thunbergii, distinctly toothed, and the fruits larger and of a more diaphanous colour. It seems not to fruit so profusely, but it is quite hardy. The ovaries contain from eight to twelve ovules, and consequently the fruits enclose more than two seeds. The species is still rather rare in our gardens. An even rarer but closely related one is the Chinese B. æmulans, differing principally by its red or purplish twigs.

The third species I wish to call attention to is B. koreana from Korea, introduced only a few years ago. I have seen bushes in Korea up to 5ft. high with red-brown, distinctly grooved branchlets. The dark green leaves are of a rather firm texture, and gain a beautiful colouring in autumn. The globose fruits of a rather yellowish red, somewhat reminiscent of ivory, form a distinct feature. They persist until the following spring. This is a remarkable and perfectly hardy species.

One of the most lovely barberries, both in flower and in fruit, is Berberis Vernæ (B. Caroli var. hoanghoensis) from north-eastern China. If I remember rightly, it was introduced by the late Mr. Purdom, who sent seeds to the Arnold Arboretum, where the plant flowered for the first time during the war. In its habit it resembles B. Poiretii, the so-called B. chinensis of gardens. The leaves and the flowers are, however, much smaller, the latter forming dense, almost stiff racemes, bearing quite a number of small salmon red fruits the colour of which is much like that of B. aggregata mentioned below. It is certainly one of the finest deciduous species known to us from China.

While the foregoing species have few or many-flowered racemose inflorescences, B. aggregata belongs to a different group. It has short and dense panicles which are erect and not pendent. They appear rather late in summer, and the fruits are smaller than those of B. Vernæ, and also differ from them by their distinct style. In its habit B. aggregata is much more like B. Wilsonæ, which is the most widely spread Chinese species in our gardens. Wilson's barberry has very delicate fruits, too, and is probably one of the best ornamental deciduous plants that its discoverer has introduced from China.

I could easily mention a good many more deciduous barberries bearing handsome fruits, but at present I have confined myself to a few desirable species which have engaged my special attention during recent months.

[CAMILLO SCHNEIDER.

UNDOUBTEDLY ONE OF THE BEST OF THE DECIDUOUS BARBERRIES, THE JAPANESE B. THUNBERGII, WHICH IN AUTUMN RESEMBLES A FIRE-BUSH WITH ITS HANDSOME RED FOLIAGE AND BERRIES.

BERBERIS AGGREGATA, WITH ITS SHORT, ERECT CLUSTERS OF SMALL FRUITS, EACH OF WHICH BEARS A DISTINCT STYLE.

A REMARKABLE AND PERFECTLY HARDY SPECIES, B. KOREANA. ITS FOLIAGE ASSUMES A BEAUTIFUL COLOURING IN AUTUMN.

NEW ZEALAND PLANTS FOR THE BRITISH ISLES

BY DR. L. COCKAYNE, F.R.S.

IN THIS ARTICLE DR. COCKAYNE TREATS OF A FEW MORE NEW ZEALAND GENERA WHICH MAY SOME DAY ADD THEIR CHARM AND BEAUTY TO THE ENGLISH ROCK GARDEN. MANY OF THESE NEW ZEALAND NATIVES, SUCH AS RAOULIAS, MAKE IDEAL ROCK-GARDEN PLANTS.

(*Continued from page* 633.)

18. Leucogenes (Helichrysum).

L. Leontopodium (North Island edelweiss, 4,000–6,000ft; more or less stony ground and rocks), one of the most lovely of alpine plants, has stems up to 9ins. high, covered closely with shining, silvery leaves. The heads on stout stalks are surrounded by spreading, snow white, flannelly bracts. L. grandiceps (South Island edelweiss, 3,000–7,000ft., on rocks and sub-alpine coarse screes) is similar, but smaller in all its parts. Both rarely flower in cultivation.

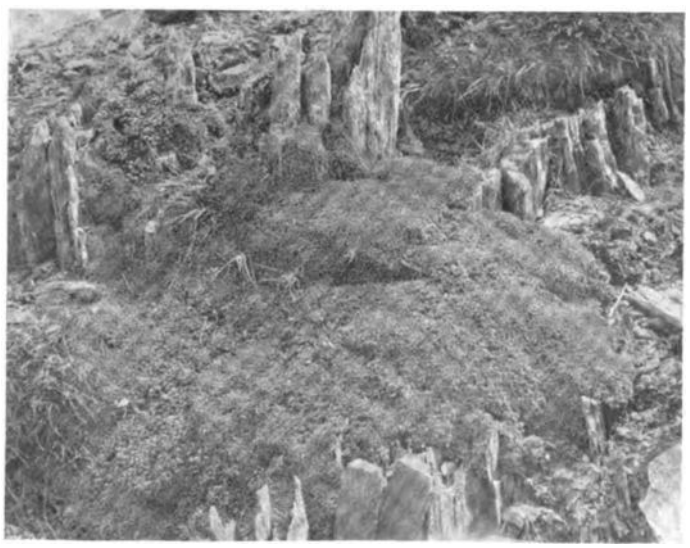
19. Linum monogynum (coast, 2,000ft., dunes, rocks) is well enough known in British gardens, but its exquisite variety chathamicum, the delicate white flowers striped or flaked with pale blue, is not in cultivation.

20. Mazus radicans (almost sea-level to 3,000ft., in wettish places) forms dense patches, the leaves brownish and blotched with purple, and the showy, fairly large flowers white with purple lower lip and yellow in the throat.

21. Myosotis (forget-me-not).—New Zealand is rich in forget-me-nots with white, yellow, blue and bronze flowers. All are beautiful except M. pygmæa, but this in some of its forms is most quaint. The sub-antarctic M. capitata is the chief of the group with its brilliant large heads of an intense blue held well above the rosettes of velvety green leaves. It is apparently more difficult to procure than to grow, for its ally, the cream-flowered, coastal M. albiflora, is easy enough. M. australis (1,000–4,000ft., in rather dry places in tussock grassland, probably not identical with the Australian species of the same name) is a slender, erect herb with fair-sized bright yellow flowers. M. explanata (3,000–5,000ft., on stones in shady river gorges) has delightful, large, white flowers. M. macrantha (3,000–5,000ft., wettish rocks) has large, yellowish-bronze blossoms. M. saxatile (4,000–5,000ft., on dry rocks) is a captivating small plant with white flowers. M. Colensoi (syn. M. decora, 2,000–3,000ft., on dry limestone screes) is a fascinating little cushion plant with its good-sized, solitary white flowers on very short stalks. MM. saxosa, Monroi, Laingii, Traversii, Lyallii and the low-growing sub-antarctic blue antarctica are one and all most desirable plants for alpine gardens.

22. Nertera depressa is well known in British gardens. N. Balfouriana (sea-level to 3,000ft., sphagnum bog, sandy peat), covered with pear-shaped yellow fruits in great abundance is equally good.

23. Ourisia.—This genus equals celmisia and ranunculus



RAOULIA HECTORI AT AN ALTITUDE OF 5,000 FT.

A BEAUTIFUL ROCK GARDEN PLANT, OURISIA MACROPHYLLA.

in the beauty and suitability of its species for the rock garden. All spread by means of creeping and rooting stems. O. macrocarpa (3,000–5,000ft., with Ranunculus Lyallii and other herbs in full sun) consists of the two varieties cordata and calycina, which have the flowers, each 1in. diameter, white with yellow eye, in five to eight superposed whorls—after the manner of Primula japonica—on stout stems up to 18ins. high. O. macrophylla (lowlands to 5,000ft.), easier to grow, is similar, but with rather smaller flowers. O. cæspitosa (2,000–5,000ft., often in more or less shade) forms dense mats of small, bright green, glossy leaves and puts forth on slender stems innumerable flowers of dainty loveliness, white with yellow eye. O. sessiliflora (3,000–7,000ft.; in stony or peaty ground) is certainly a gem with its large flowers (for its size), two to eight on a stem, standing out of the pale green, hairy rosette of crinkled leaves. The variety splendens (name not yet properly published) is still better with its more hairy leaves and larger flowers. O. Cockayniana, O. glandulosa and O. prorepens, all high mountain species, forming floriferous mats, are eminently desirable plants.

24. Oxalis lactea (lowlands to 4,000ft., moist banks, open forest on sphagnum) is a pretty wood sorrel with delicate white flowers.

25. Phormium Colensoi (coastal to 4,000ft., all kinds of growing places) has yellow flowers, stiff or drooping leaves according to the variety, and drooping, twisted, pointed seed-pods. It is smaller and far more hardy than the well known P. tenax.

25. Pleurophyllum.—The sub-antarctic P. speciosum is the most stately and likewise handsome species of the flora, as also one of the finest herbaceous plants in the world. Briefly, it is a glorious gigantic Michaelmas daisy. The four or five fleshy, corrugated, hairy, ovate leaves, each about 2ft. long by more than 1ft. broad, looking like pale green velvet, lie on the wet ground as shallow goblet-like rosettes, out of which in December (early summer) rise the massive flower-stalks for 3ft., carrying about fifteen heads, each 2ins. in diameter, with dark purple disc and pale purple rays. This glorious plant grows in its hundreds, exposed to the bleak, sunless climate, on deep wet peat in close company with its still taller relative, P. criniferum, Anisotome latifolia, Chrysobactron Rossii, Stilbocarpa polaris, Gentiana cerina, certain great tussock grasses and the dark-leaved fern Polystichum vestitum, while a few sea lions lie half-hid among the rich foliage. Surely this is a wonderful natural garden at almost the limit of flowering plants in the Southern Hemisphere but equidistant from the equator only as Tavistock in Devon! Near the

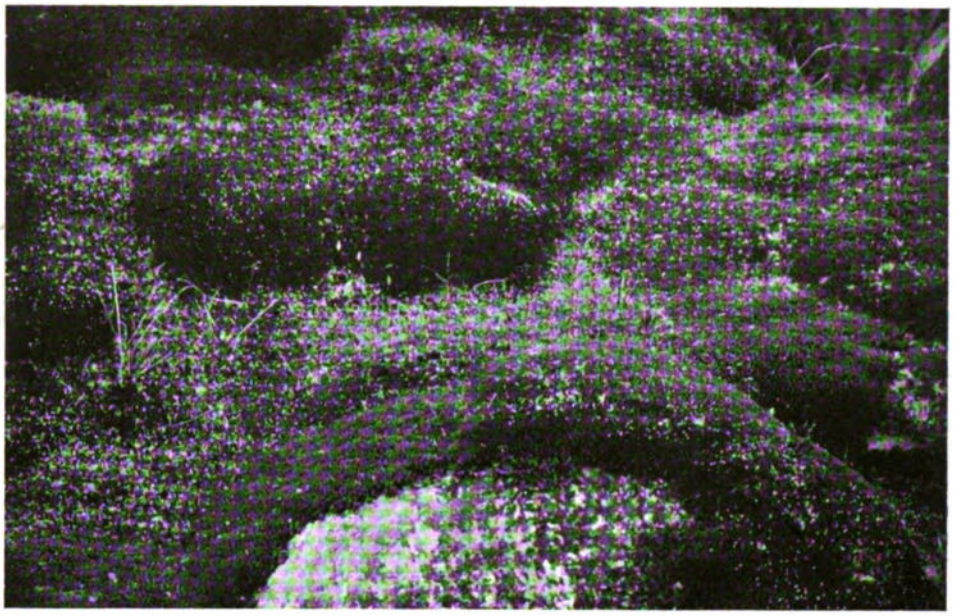
Digitized by Google

summits of the hills grow the smaller, more celmisia-like Pleurophyllum Hookeri with its silvery rosettes, and mats of the exquisite Celmisia vernicosa and abundance of the supremely lovely Myosotis capitata.

26. Pratia angulata (sea-level to 4,000ft., in wettish places) is a pretty white-flowered, mat-forming lobelia with good-sized purple fruits. P. macrodon (3,000–6,000ft., stony ground), its longer flowers tinged more or less yellow, is more hardy.

27. Ranunculus (buttercup).—The big New Zealand buttercups are the aristocracy of the genus. The celebrated mountain lily (Ranunculus Lyallii) stands supreme with its great saucer-like, peltate, smooth leaves raised high on long stalks, the broad, massive rhizome partly out of the ground, and the erect, branched peduncle carried far above the leaves, bearing from thirty to sixty pure white, sometimes semi-double flowers, each the size of half a crown. Its commonest habitat is fairly well drained soil exposed to the full sunshine (the heat is sometimes great) at from 3,000ft. to 4,000ft., but it likewise grows in open places among shrubs and in shaded places where peaty soil has accumulated on rocks. R. Buchanani (4,000 – 6,000ft., stony ground), also with white flowers, is almost as beautiful. R. Matthewsii is a hybrid ranging in character between the two. R. insignis (3,000–5,000ft.; somewhat stony ground), with many brownish hairs on its great leaves, has huge golden yellow flowers in profusion. R. Godleyanus, another yellow-flowered giant, has smooth leaves. The most readily grown of these lordly buttercups is R. lobulatus, but its abundant yellow flowers are smaller than in its relatives.

28. Raoulia.—Many of the species of this genus play much the same part in alpine gardening as the mossy saxifrages. They form mats, or low dense cushions, some green, others silvery; the small flower-heads are conspicuous through their abundance, and they give forth a delicious honey-like fragrance. Most grow on stony river-beds in the full sunshine. The following are the best: R. australis (silvery), R. Parkii (similar but with white bracts to the heads), R. lutescens (dense, silvery cushions), R. tenuicaulis (silvery and green, of rapid growth), R. subsericea (green) and R. glabra (similar to the last). R. grandiflora greatly resembles a silvery cushion celmisia with its large flower-heads with white petal-like bracts. It is an ideal rock garden plant. Then there are the more difficult R. Hectori (purely alpine, silvery) and the dense green cushion plant, R. Haastii. Some of the species form gigantic cushions, but they are extremely difficult — perhaps impossible — to grow. R. eximia shares with Haastia pulvinaris the name "vegetable sheep."



THE DENSE GREEN CUSHIONS OF RAOULIA HAASTII.

RAOULIA EXIMIA, APTLY CALLED THE "VEGETABLE SHEEP."

(*b*) SHRUBS AND SMALL TREES.

Here only a few high mountain woody plants are dealt with, especially those but little known in the British Isles. Many equally good have to be omitted, nor is anything said about the fine evergreens, so suitable for the warmer parts, some of which with but slight protection succeed in colder localities.

1. Carmichælia (New Zealand broom).—The dwarf species of stony, dry ground are excellent, uncommon-looking shrubs, 1in. or 2ins. high, with their green or yellowish, flattened stems and pea-like, purple-striped flowers. C. nana, C. Enysii, C. Monroi and C. uniflora are well worth attention. C. compacta, a bushy, leafless shrub of arid hillsides, 2ft. to 3ft. high, is extremely floriferous and graceful.

2. Cassinia albida (almost sea-level to about 4,000ft., dry ground, forming low thickets), about 4ft. high, is pleasing when well grown with its rather small, viscid, dark green leaves, whitish beneath and masses of flower-heads. The var. canescens is more or less hoary, or almost white in one excellent form not in cultivation.

3. Clematis afoliata (sea-level to 2,000ft., dry places, rocky ground) forms curious, entangled masses of leafless, rush-like stems and bears abundance of fragrant, yellow flowers. The male, as in all New Zealand species of clematis, is far the more showy. Seed takes about a year to germinate.

4. Coprosma brunnea (500 – 3,000ft., stony ground in the full sunshine) is of exquisite beauty when the wiry, procumbent stems resemble strings of beads, covered as they are with translucent, jewel-like drupes, in colour sapphire blue, darker blue, pale blue and white.

(To be continued.)

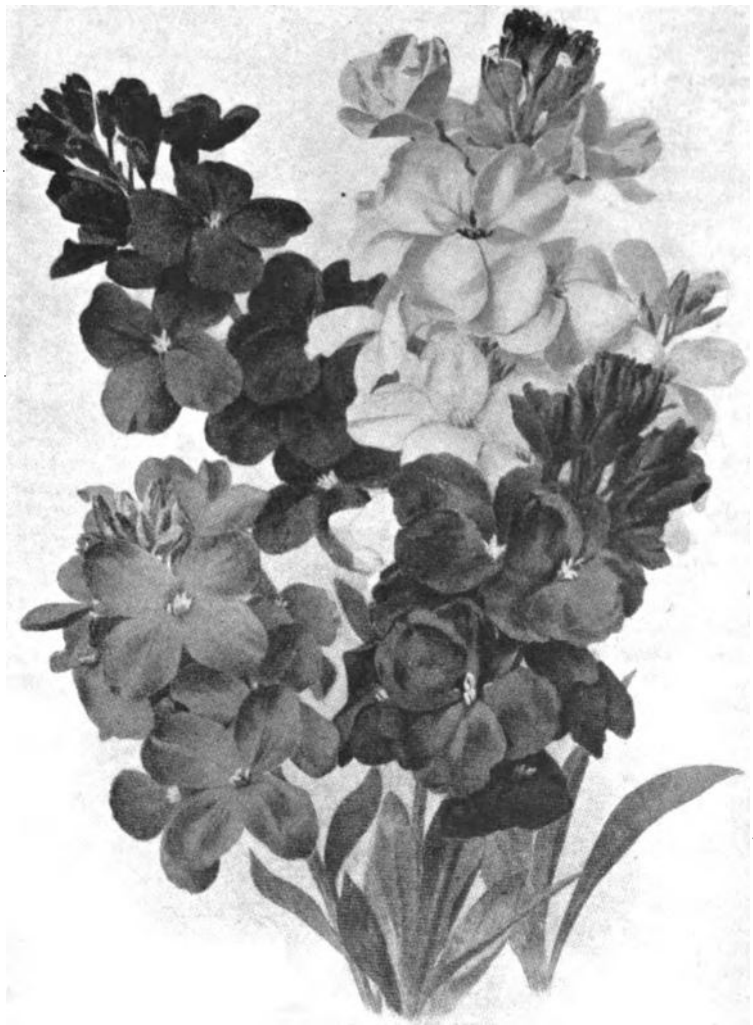
THE CULTIVATION of WALLFLOWERS

THE common wallflower (Cheiranthus Cheiri) is one of the oldest cultivated plants, the date of its introduction from South Europe being given as 1573; yet it never grows old nor loses its fascination among garden lovers generally. Old-time sentiment, early flowering, bright and varied colours, delicious fragrance and an abundance of large flowers are sufficient to account for its popularity. It is usually grown as a biennial, and doubtless the finest flowers and the greatest quantity are obtained from it when so treated; but it is a true perennial and even sub-shrubby when allowed to grow undisturbed for a number of years. This habit can be well seen when it grows upon old castle walls in various parts of the country, or on the chalk cliffs of Kent, where the flowers are small and yellow, but delightfully fragrant. Like the antirrhinum it is a true wall flower, with its very dwarf and woody stems when growing under such conditions, while it never looks more natural nor suffers from the severest of our winters. Its extended cultivation upon old walls would be appropriate.



A CHOICE GROUP OF WALLFLOWERS.
These plants owe their popularity to their early flowering, bright and varied colours, and their delicious fragrance.

CULTIVATION.

For spring bedding and garden adornment generally, the biennial system of treatment is best because the largest flowers and the greatest quantity of them can be obtained in a given space, and on dwarf and bushy plants. Any good or average garden soil, if well drained, may be made to give perfectly satisfactory results. Clay soils and those of a very peaty character are the worst, though it will grow quite well in either, if a sufficient quantity of sand is well mixed with them. Rich and damp soils encourage rampant and soft growth which is ill calculated to withstand a severe winter. Open situations are best for most of the modern varieties, but exposed and windy positions should be avoided or the large flowers will be liable to injury. From this point of view the value of shelter is well demonstrated in the front gardens of villas, or when narrow borders close to the walls are occupied with these flowers.

The seeds should be sown thinly in lines, 12ins. apart, in a reserve part of the garden, to give facilities for hoeing and keeping down weeds. This should be done in May or up to the first week in June, to allow time for the plants to mature and flower well the following spring. As soon as the seedlings are one or two inches high they should be transplanted to a piece of prepared ground, in lines 12ins. apart, and 6ins. to 9ins. between the plants. If the ground requires digging, it should afterwards be trodden firmly to ensure dwarf, sturdy and bushy plants, which are the best for all purposes. This stage is the most critical in the rearing of the plants. If the seeds were sown thickly, and the seedlings neglected till they get tall, they get drawn up in spindly fashion with a single stem. Some resort to pinching to make them bushy, but that means loss of time, and the plants are unable to produce strong branches before autumn, with the result that the flowers are few and poor the following spring. The results are equally or more disastrous when leggy plants are inserted too deeply in heavy, clay soils. In severe winters most of those plants die, and have an unnatural, planted appearance as long as they continue to exist. Small seedlings can be dibbled into lines quite speedily; but somewhat larger ones with plenty of roots are best planted with a good trowel, alongside the garden line.

FINAL PLANTING.

This can be done in September or October, the latter month being the most convenient, if the wallflowers have to occupy beds filled with summer-flowering plants, which often remain gay till well into the autumn. In any case, autumn planting is best, because the wallflowers have time to get partly established before winter. Late spring planting is the worst, because they lose a great part of their foliage, and the flowering period is upon them before they have time to make sufficient roots to support a full display of flowers. Wallflowers take kindly to a good deal of bad usage, however, and that tends to make some people remiss or careless. A bed may be filled entirely with wallflowers, or they may be planted sufficiently far apart to allow a groundwork of arabis, aubrietias, forget-me-nots or polyanthuses to be seen. A good contrast can be made by planting them more closely and filling the interspaces with daffodils which will just show themselves above the wallflowers in spring.

SINGLE WALLFLOWERS.

The original colour of the wallflower was pale yellow; but now the shades of colour or mixtures of them are more

Digitized by Google

numerous than the average cultivator generally imagines, while improvement still continues. In my opinion Fire King is the greatest advance at present in commerce, by virtue of its rich vivid orange colour which shows up clearly from a distance. It is by no means the darkest. The flowers reach their greatest perfection when sheltered by a wall. Orange Bedder is dwarf and is rich orange when it first opens, shading off to apricot.

The yellow shades are the most conspicuous of all at a distance, and are the last to disappear in the gloaming. Their names indicate the shade of colour in most cases, namely, Cloth of Gold, Rich Yellow, Golden Monarch, Primrose Monarch, and Apricot. A distinct and pleasing pale yellow is that of Faerie Queene; while Old Castle is the pale yellow wild form that takes care of itself on old castle walls and ruins.

YELLOW WALLFLOWERS ARE HANDSOME EVEN AT A DISTANCE.

Crimson is represented by Vulcan and Giant Vulcan, while Blood Red and Giant Blood Red are of another shade of reddish crimson and much valued by many cultivators. Darkest of All is of a rich maroon and makes a striking contrast with the green foliage in bright weather when the sky is clear.

Ruby colours are represented by Ellen Willmott (pure ruby), Ruby, Purple, and Purple Queen (purple to ruby). An early-flowering variety named Harbinger has brown flowers. Light Brown is the old iron brown wallflower of Thomson, the author of "The Seasons." A few of the varieties have what I look upon as fancy colours. The most popular, perhaps, is Eastern Queen, the flowers of which open of a light apricot or chamois hue and change to rosy pink. Rosy Gem originated as a sport from Fire King and has deep rose-carmine flowers. Ivory White and White Gem are strains from which the colour has almost disappeared, leaving the flowers of a creamy white. These two are best raised in cold frames, because of weak growth at first.

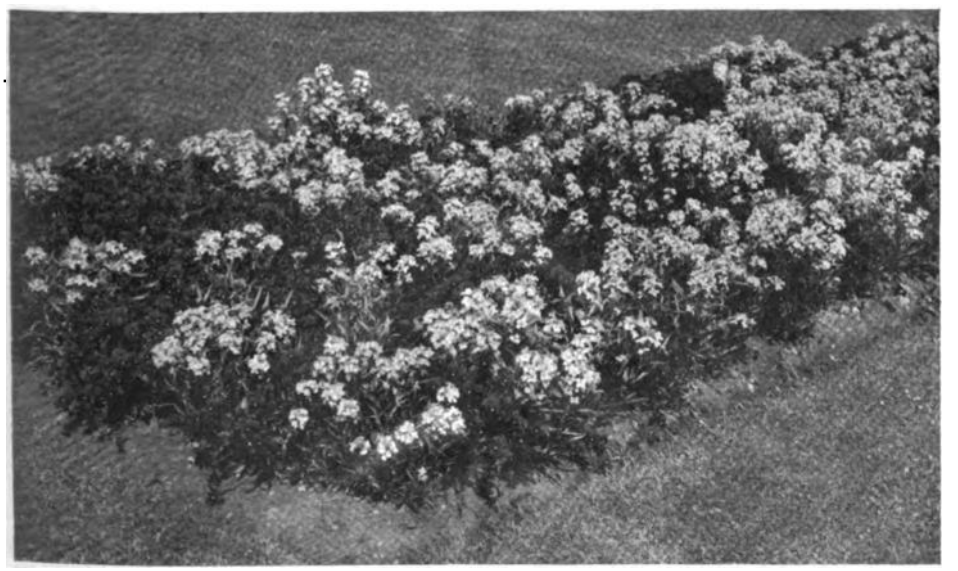
The old Parisian Early Wallflower was a variety that commenced to bloom in four months from seed and kept on for some months. In the hands of British nurserymen it has been developed into a considerable number of coloured forms, of dwarf habit, but not all as equally early as the original. Sown in May outdoors, they commence blooming in autumn with me, and some of them in uncultivated ground have bloomed for three years, continuing in flower, weather permitting, till May, and sowing themselves. The yellows are very handsome even at a distance, and include Yellow Phœnix, Belvoir Castle, Dwarf Yellow and Primrose. Phœnix itself is dark brown, and Dwarf Red and Vulcan are other early varieties.

DOUBLE WALLFLOWERS.

There are two strains of the above, the old double which bore a tall single spike of very fragrant double flowers. Improved Double is an advance upon it. A newer strain, named Double Dwarf Branching, is of bushy habit, with many short spikes of double flowers. The double yellow wallflower Harpur Crewe can scarcely be omitted here by reason of its suitability for planting on elevated parts of the rockery. It is propagated by cuttings.

One meets with many intermediate forms between the typical single-flowered varieties and the strains of the true double kinds. The latter, although in every way handsome in appearance, do not seem to have the same attraction for one as the real old sorts. No doubt, sentiment to a certain extent accounts for this, due, in no small measure, to the fact that the wallflower, as already pointed out, is one of our oldest garden flowers in cultivation. It is well not to lose sight of these plants, with all their old associations of the long ago days, as they serve to make one appreciate all the more the trend of our modern plants and gardens.

J. FRASER.



CHEIRANTHUS ALLIONII, PLANTED EFFECTIVELY WITH A GROUNDWORK OF VIOLAS.

FORTHCOMING EVENTS.

September 23.—Royal Horticultural Society's Autumn Exhibition at Holland Park Hall, Shepherd's Bush (three days). A great autumn show of flowers, with a display of autumn foliage and berried plants.

October 1.—Glasgow and West of Scotland Horticultural Society's Meeting.

October 4.—Blackburn Horticultural Society's Meeting.

October 7.—Royal Horticultural Society's Fortnightly Meeting (two days).—Royal Caledonian Horticultural Society's Meeting.

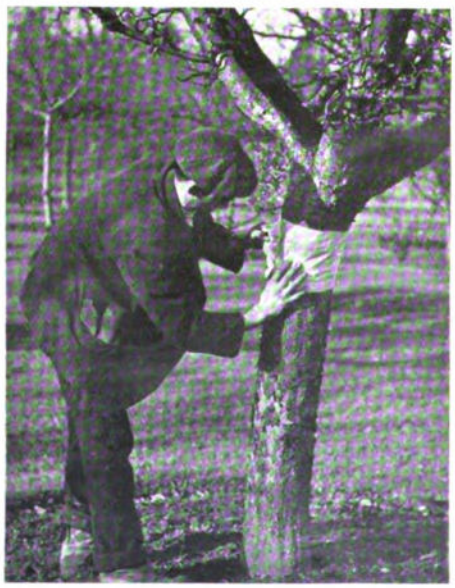
GREASE-BANDING OF FRUIT TREES

DURING recent journeys through commercial fruit-growing districts, widely varying conditions of crops have, as usual, been noted, and by inquiring into details of culture one discovers that there is generally a fairly well defined reason which is tendered as an excuse for severe attacks of the common pests of the orchard. Thus the owner of an orchard whose apples and pears are suffering very badly from scab explained that owing to the illness of his foreman he did not manage to get the lime-sulphur spray used. Another whose heavy crop has been sadly diminished by maggot, which has caused the fall of the bulk of the fruit, regretted that through one cause and another his grease-banding had last autumn been so long delayed that the wingless moths had reached the upper branches of the trees before the deterrent was applied; while yet another was similarly suffering because he had read that it should not be considered essential to grease-band every year, but that if one season the bands catch a heavy crop of moths the trees will probably be clear for the next two or three years. His bands had been thickly coated with moths in the winter of 1922-23, and he had economised by dispensing with grease-banding during the winter 1923-24. His apples are now in very bad plight. I have a considerable amount of sympathy with that man, for I recall the reading of the article which, in urging the necessity of rigid economy in commercial fruit culture, had erred in advising too hasty a suspension of preventive measures.

It is undoubtedly very essential that even in matters of combating pests and diseases the grower for profit shall exercise judicious care in expenditure of cash on materials and labour. Had the advice been to discontinue grease-banding after one season had passed with the bands remaining clean on the trees all might have been well, but when the



A GOOD STOUT BAND BEING APPLIED WITH PASTE.

SCRAPING THE STEM.

bands are thickly covered with captured moths it may be taken for granted that some have still escaped destruction, for even the carcasses of the dead will form a bridge over which later moths may pass without getting their feet entangled in the adhesive grease.

Private garden owners who have only a few fruit trees, the crops of which they desire for use in their own households, are not so seriously concerned with the actual cost of preventive and curative measures, and in order to make doubly sure that crops once set shall be protected from ravaging foes it is prudent to grease-band and to spray persistently and thoroughly until the time arrives when the trees are known to be perfectly clean.

It is, moreover, wise to begin grease-banding at an early date. The several species and varieties of wingless moths become active at varying dates or periods during autumn, winter, and even until March. The recognised "opening" of their active season is early October, but if grease-bands are not applied until October it is quite possible that a day previously one or two precocious insects may have passed up the trunk and reached the branches of a tree, and even one moth will deposit sufficient eggs to produce a destructive horde of larvæ. It is surely infinitely better to get the bands on the trees before the possibility occurs of even the first moth escaping the trap. Mid-September is not too early to start.

The application of grease-bands to standard trees is quite a simple matter, but bush trees involve a deal more labour, since the only really effective plan is to band each main branch separately. Here again the advice is sometimes given that in view of the greater labour involved it is well to omit grease-banding bush trees and rely upon spraying with lead arsenate. However sound this may be in regard to commercial plantations, it is poor advice for the private garden owner. Often his fruit is underplanted with small crops, and there is risk in the use of lead arsenate where cauliflowers, kale or lettuce may be growing within reach of the poisonous spray, and where one's horticulture is a hobby and recreation, the time involved in effectively grease-banding has not to be reckoned at its cost per hour.

Let the band be of good, stout, grease-proof paper. Be careful that it is wrapped very smoothly round the tree, and tied quite securely. A carelessly wrapped band may leave a fold which provides a safe tunnel under the paper through which some moths will make their way. The raffia used for tying must be broad and strong.

Use a good grease, and lay it on the band evenly. It would be out of place for me to advise one particular brand of grease. The manufacturers are well aware that it is only by producing a really good article they can successfully compete with other brands, and any of the advertised greases sent out by well known firms are efficient if properly handled.

Much depends upon the weather. Prevalence of drying winds may form a dry film or skin over the surface. Rain should have little or no effect for a while, but long continued or frequently recurring heavy storms may eventually reduce the adhesive power of the best of preparations, and it is well to go over the trees at frequent intervals for the purpose of recoating any bands that may have dried out.

Should it happen that from any cause a band perishes, necessitating the application of a fresh band, it is well to place it just above the previous band, for it cannot be said that the covering of a complete ring of bark for a period of six months or more is exactly a good thing for any tree, and when a change has to be made it is as well to release the old spot from its covering and give the second period a change of position.

PUTTING ON THE GREASE.

Digitized by Google

About 3ft. from the ground is near enough for the bands. If the trees are grown on dug ground a band at a lower position may become bespattered with mud during heavy storms, and on grass a tall stem may provide a ladder up which an energetic moth may travel to reach the tree trunk above the band.

Brown paper is sometimes used, but unless well glazed it is generally sufficiently absorbent to take a proportion of moisture out of the grease.

It is well to state that grease-banding must not be considered an all-sufficient substitute for spraying. It cannot prevent attacks of aphis, nor has it any power against fungoid diseases, but as a means of arresting the wingless females of the winter moths, the umber moths, the March moth, etc., grease-banding is a thoroughly practical and highly essential item in the fruit grower's programme. As such it should not be overlooked or neglected. A. J. MACSELF.

GLADIOLI AT VINCENT SQUARE

IN spite of the recent wet weather, the numerous exhibits of gladioli and dahlias at the fortnightly meeting of the Royal Horticultural Society on September 9th were exceptionally good. The presence of so many dahlias was due to the fact that the National Dahlia Society was holding its Show the following day.

Messrs. Kelway and Son had an extensive collection of large-flowered hybrids. Of outstanding merit were: Kelway's Masterpiece, ruby crimson, dark spot; Sunset, rosy pink, suffused violet; Purple Rod, purple with yellow blotches; Edward VII, scarlet crimson; Duke of Richmond, rose, large white spot; Sir Edward Carson, mahogany, shaded maroon.

In Mr. Alfred Edwards' exhibit the following primulinus hybrids were conspicuous: Fire Queen, scarlet; Yellow Standard, deep yellow; Constance, creamy pink; Souvenir, yellow; Ethel, soft salmon pink. Among the large-flowered varieties we noted Lord Nelson, orange, shaded yellow; Panama, deep pink; Faust, deep crimson; Baron Hulot, indigo blue; and Clear Eye, scarlet, white blotch.

Messrs. R. H. Bath, Limited, had a large exhibit. Noteworthy large-flowered sorts were Baron Hulot; Love's Fire, scarlet; Yellow Hammer; Red Canna; and Orange Queen.

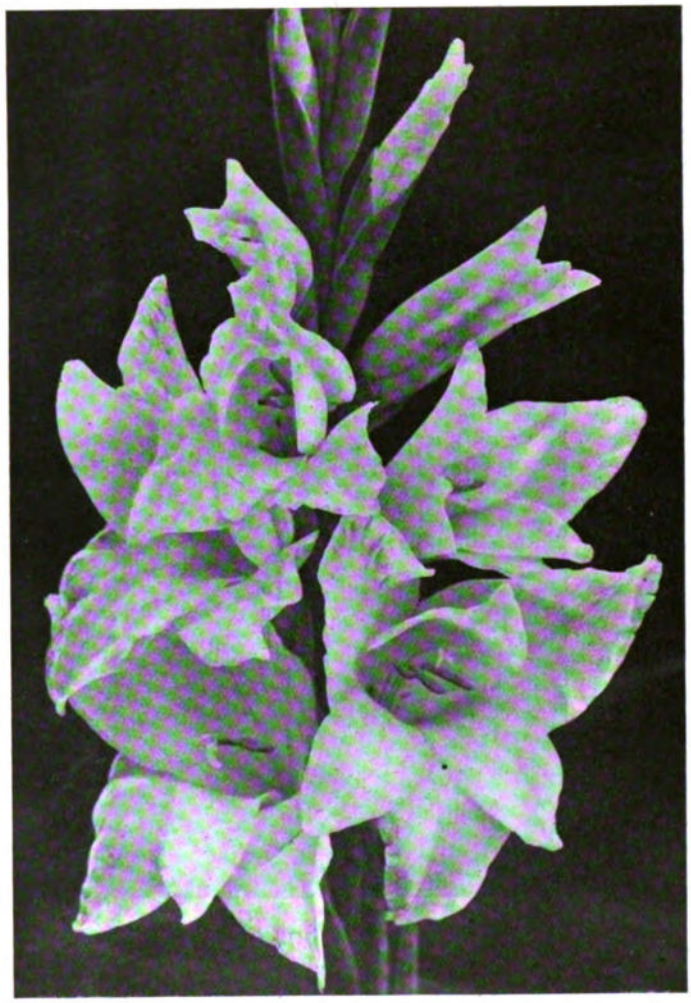
Messrs. Velthuys and Co. of Hillegom, Holland, who are wholesale nurserymen, showed a well arranged exhibit of large-flowered "glads." Of outstanding interest were Master Wietse, violet blue; White Giant; Pink Perfection; Orange Brilliant. They also showed dahlias.

A very large collection of gladioli was staged by Messrs. W. Artindale and Son. Here were such sorts as White Giant; Golden Drop; Empress of India; Marechal Foch, salmon pink; Brimstone, sulphur yellow; Prince of Orange; Maiden's Blush; Apricot and Pink Beauty.

In Messrs. Lowe and Gibson's exhibit we noted such large-flowered sorts as Catherina, pale blue; Rev. Ewbank, lilac; Nora, light blue; Mr. Mark, lilac, dark blotch. Good primulinus sorts were Souvenir, Black Pansy and Sappho. This firm also showed some very promising seedlings.

Besides the gladioli there were many exhibits of other flowers and plants.

Messrs. J. Cheal and Sons had a very interesting exhibit of flowering and fruiting shrubs. Here were well fruited sprays of Leycesteria formosa, Viburnum Opulus, V. rhytidophyllum, Cotoneaster frigida and Symphoricarpus racemosus. Among the flowering shrubs we noted Fuchsia Riccartonii, F. americana elegans, Potentilla Farreri, Hedysarum multijugum, Buddleia Pink Pearl, B. magnifica, Tamarix odessana, Choisya ternata and Hydrangea paniculata grandiflora.



A FINE SPIKE OF THE LARGE-FLOWERED GLADIOLUS WHITE GIANT.

Mr. T. Carlile showed herbaceous phloxes, Delphiniums Dusky Monarch, Norah Ferguson, Daphne and Millicent Blackmore. He also showed a few spikes of red-hot pokers (kniphofias).

Perpetual-flowering carnations, perpetual borders and Dianthus Allwoodii were staged by Messrs. Allwood Brothers. Mr. C. Engelmann and Messrs. Stuart Low and Co. also showed perpetual-flowering "cars."

A large collection of chrysanthemums was staged by Messrs. Keith Luxford and Co. Here were to be seen such excellent sorts as September White, September Yellow, Autumn Beauty, Verona, Framfield White, Goldfinder (an excellent yellow variety) and Improved Masse.

Bronze-coloured "mums" were exhibited by Messrs. Scott and Wickham.

Several dishes of apples and pears were shown by Messrs. Laxton Brothers.

Messrs. Daniels Brothers showed their new September Black Currant, together with apples and pears.

Black and white grapes were staged by Mrs. Reed of Devizes.

Hardy plants were shown by Mr. F. G. Wood, Messrs. B. Ladhams, Mr. William Yandell, Messrs. Reamsbottom and Co., the Misses Hopkins, Messrs. Rich and Co., Messrs. Isaac House and Son, and Mr. Amos Perry.

Mr. J. J. Kettle exhibited Violet Princess Mary and his perpetual raspberry Lloyd George. The only exhibit of roses was by the Rev. J. H. Pemberton.

Dahlias were exhibited by Messrs. Sutton and Sons, Messrs. Dobbie and Co., The University College, Reading, Mr. J. B. Riding, Messrs. Carter Page and Co., and by members of the Netherland Dahlia Society.

Messrs. R. and G. Cuthbert showed giant-flowered streptocarpus and a large quantity of Nerine Fothergilla major.

Messrs. L. R. Russell and Co. showed clematises grown in pots, also evergreen and berried shrubs.

As noted elsewhere, this was a gladiolus show, and competition in the classes provided for this flower was much keener than is usual at Vincent Square. The Foremarke Cup offered by the Royal Horticultural Society for the best twenty spikes (distinct kinds) was won very handsomely by Mr. D. Whitlaw, of Stationhouse, Laurencekirk, whose spikes were, however, very obviously opened under glass. The remaining exhibits were all from outdoors, and that of Major Geo. Churcher, especially, was very creditable and well deserved the silver Banksian medal awarded. The National Hardy Plant Society had some eighteen classes for large-flowered and primulinus varieties and table decorations, and all except those for new varieties attracted fairly good entries. The bloom shown was representative, although in some cases a little battered, which, considering the inclement weather, was not surprising. The principal prizewinners were Major Geo. Churcher, Mr. W. Kitchener, Messrs. Lowe and Gibson, Messrs. D. Prior and Son, Mr. A. E. Amos, Mr. A. Amos, Mr. S. H. Gregg, Messrs. Artindale and Son and Mr. A. Edwards.

The Show would suffice to prove to any in doubt the rapidly increasing popularity of the gladiolus, and particularly of the graceful and decorative primulinus varieties.

NEW AND RARE PLANTS.

HIBISCUS WAIMEÆ.—The large white flowers of this temperate-house species are remarkable for the long crimson staminal column. The leathery foliage is oblong and rather congested, and the plant perhaps more interesting than beautiful. Award of merit. Shown by the Director, Royal Botanic Gardens, Kew.

DAHLIA MRS. SKEVINGTON.—A yellow-pink, peony-flowered variety of good size, beautiful colouring and exquisite form. The flowers are borne on long, stiff stems. Shown by Mr. A. J. Cobb.

ORCHIDS.

CATTLEYA JOYCE HANMER.—An attractive hybrid of unknown parentage, but possibly derived from C. iridescens (bicolor × El-dorado). Flower of medium size, bright canary yellow, labellum of slightly deeper tint and bordered with soft crimson. Award of merit. Shown by Mr. R. Gerrish.

ODONTIODA JUANITA (Oda. Brewii × Odm. Pharos).—This novelty carried an erect spike bearing six flowers, well above the average size for this section, of reddish chocolate colour, the broadly developed labellum having a crimson over-tint and bright sheen. Award of merit. Shown by Mr. R. Gerrish.

SOPHRO-LÆLIO-CATTLEYA ISABELLA VAR. VIVID (S.-L.-C. Marathon × C. Fabia).—The spike bore a couple of well developed flowers, roundly proportioned, of soft rosy buff tint, the labellum having a marginal area of deep ruby-crimson, with a gold venation in the central area. Award of merit. Shown by Mr. H. T. Pitt.

BRASSO-LÆLIO-CATTLEYA J. M. BLACK (L.-C. Firminii × B.-L.-C. The Baroness).—A fine addition to the yellow section, the present novelty being of buttercup yellow, the sepals lightly spotted on the exterior with crimson-red, the labellum having the central area of ruby-crimson, and a narrow band of the same colour on the extreme margin. Award of merit. Shown by Messrs. Flory and Black.

LÆLIO-CATTLEYA VEGA (L.-C. rubens × L.-C. Soulange).—A handsome flower with all the segments broadly developed, of rosy purple colour, the wide labellum royal purple and with the margin prettily crisped. Award of merit. Shown by Messrs. J. and A. McBean.

THE NATIONAL DAHLIA SOCIETY'S SHOW

THE Annual Show of the National Dahlia Society, which was held in the Royal Horticultural Hall, Westminster, on September 10th, was the most successful held by the Society of recent years. The hall was pleasantly filled with dahlias of good quality. H.R.H. Princess Louise performed the opening ceremony in a gracious and charming manner, and there was a good attendance.

The enthusiast, on entering a flower show, always looks first for the newest or for something novel, and these were to be found *en masse* at the New Plant stand and in the large exhibit so tastefully arranged by Messrs. Sutton and Sons. Our remarks on the new varieties are herewith appended. The novelty of the Sutton exhibit lay in its being composed solely of blooms from seedling plants.

All possible types of dahlias were represented, and these included so many really excellent blooms that a gold medal was awarded for the group. Large vases of mammoth decorative dahlias, dwarf singles, show singles, cactus dahlias, dwarf pompons, collarette dahlias and such were equally well represented.

Of the general trade collection of dahlias the outstanding exhibit was that so charmingly arranged by Mr. H. J. Jones, and this won the premier award of a large gold medal. Mr. Jones has been awarded many gold medals for exhibits of different flowers, but none has been more fully deserved than this one. Not only was the collection composed of very representative high quality blooms, but the arrangement was most artistic throughout. No matter whether it was a tall stand of such large decorative varieties as J. G. F. van Tets, Orange Boven or Princess Mary, a basket of mixed pompons, or cactus, or the old show varieties, each separate receptacle was as artistically satisfying as may be conceived. Evidently realising that at this Show "the dahlias are the thing," Mr. Jones eschewed the use of large foliage and wisely contented himself with graceful sprays of late-flowering Michaelmas daisies, Gypsophila paniculata, thalictrum and similar plants in sufficient quantity to soften the outlines and add grace. He is to be congratulated on a most successful display.

These large trade collections were an important feature of the Show, and often illustrated in a fascinating manner the great decorative value of dahlias when arranged boldly. The baskets delightfully arranged by Messrs. Wm. Treseder, Limited, and Mr. Jarman were notable examples, while Messrs. Dobbie and Co. had a large collection of collarette varieties, many of their own raising. Another valuable group was that from the University College Gardens, Reading, and in this Mr. A. J. Cobb set out admirably a large number of decorative varieties raised by himself. They were mostly of the miniature peony-flowered type which becomes a medium-sized plant with a minimum of foliage and plenty of lovely flowers well set up on long, slender, but stiff stems.

MR. JONES' LARGE GOLD MEDAL EXHIBIT, REMARKABLE FOR THE EXCELLENT ARRANGEMENT OF THE INDIVIDUAL VASES.

As garden plants these miniature peonies are unequalled among dahlias. They do not require a deal of space, they flower early and continuously till frosts come, and are most charming cut flowers. A delightful variety at the Show was Mrs. W. M. Childs, of golden buff colouring heavily tipped with clear rose pink. For those who prefer a more solid bloom of medium size there are the miniature decorative varieties, which are fully double and of satisfying colours. The most substantial of all the dahlias are the old show and fancy varieties. These had a long vogue with fanciers, then, with the swing of the pendulum of floral fashions and changes, much ink and breath were wasted in deprecating their formality. But it must be admitted that this type has distinct value, as was to be seen in the vases of Mr. H. J. Jones and in the splendid first prize exhibit of Messrs. Wm. Treseder, Limited. These latter were, of course, shown in the old style on boards. It was a superb exhibit and included such sorts as Tom Jones, John Walker, Gracchus, Prince of Denmark and George Charlton.

The dainty little pompon dahlias were seen to perfection in several exhibits, though we would prefer them without the stiff wire arrangement so many exhibitors affect. The real charm of the pompons was best seen in the delightful dinner-table decoration by Mr. D. B. Crane, which, however, did not find favour with the judges. There seems to be a general impression that pompon dahlias make a preponderance of foliage which hides the flowers and so are not good garden plants. This is not so, unless the ground is heavily manured. With perhaps the exception of the white-flowered varieties, the pompons, under sensible cultivation, show their flowers well. The following were selected at the Show as being a good selection for all purposes: Mars, scarlet; Nero, very dark maroon; Adelaide, pale

Digitized by Google

lilac ; Nerissa, rosy mauve ; Clarissa, yellow ; Little Jim, bright maroon.

In the search after size of bloom and, most particularly, for length of flower-stem in order to obtain varieties which will disclose the blooms when on the growing plant, we are rather inclined to the opinion that the newest cactus dahlias have lost a deal of the charm of form possessed by the older sorts. Many of the newer varieties have straight, though rolled, florets and, to us at any rate, are not so fascinating as when they are curved. We are at one with those who desire a race of cactus dahlias which will be beautiful in the garden as well as when cut, and no doubt it is only a question of time when length and strength of stem will be combined. Champion, orange scarlet ; John Riding, deep vermilion ; Lavinia, scarlet ; Canary, yellow ; Bonny, white, tipped with lilac ; Gigantic, orange buff ; Valour, vinous crimson ; Abbotsford, yellow, heavily flushed with rose at the tips, were good examples of the cactus varieties on show.

In the open classes the chief prizewinners were Messrs. Wm. Treseder, Limited, Messrs. James Stredwick and Son, Messrs. J. Cheal and Sons and Mr. H. Woolman, all of whom staged exceedingly good blooms.

Among the amateurs Mr. W. G. Cramp, Streatham ; Mr. A. Brown, Leagrave ; Mr. M. Howard, Chesham ; Mr. F. Chennetts, Wheathampstead ; and Mr. S. Amos, Colchester, won most of the first prizes.

The decorative classes were very popular, and many admirable arrangements were to be seen. Mr. D. B. Crane, with a charming table of a soft yellow shaded with rich terra-cotta variety, won the first prize in the dinner-table class restricted to star varieties, and was also first with glorious blooms of Dazzler in the class for three vases for sideboard decoration.

In the dinner-table class, where star dahlias must not be used, Messrs. Wm. Treseder used Mary Poynter, a lovely rose shaded miniature peony variety and deservedly won the first prize. Mrs. Courtney Page was second with a very artistic arrangement of Dahlia Picture, fruiting sprays of berberis, and trails of Virginian creeper. Mrs. E. M. White won two first prizes with well arranged vases of dahlias, and Messrs. Wm. Treseder had the best bowl.

NEW DAHLIAS.

The Joint Committee, composed of members of the National Dahlia Society and the Royal Horticultural Society, met in the morning to consider the merits of a large number of new seedling dahlias. A liberal selection was made for "trial at Wisley," and of these we consider the following to be the most valuable :

BURSTOW STAR.—A very pretty little variety of the useful star type. The rosy mauve florets are gracefully rolled and the flower has a definite deep crimson zone. The name of the sender was not given.

IRVINA.—This is a very decorative, small peony-flowered novelty. The bright rose pink flowers are borne on long slender stems. The name of the sender was not given.

MARY.—A medium-sized peony-flowered variety with plenty of rich velvety maroon florets. The colouring is very uncommon and it found many admirers. The name of the sender was not given.

MRS. EUSTACE BERRY.—An uncommon collarette dahlia. It is a very round bloom of good substance. The florets are a rich velvety crimson, while the milk-white quills, which stand out well, are striped with crimson. The name of the sender was not given.

NIGRA.—This was the most uncommon new dahlia in the Show. Long shoots were included to show the habit of the plant, which seems to be exceptionally graceful, and this variety would be well worth growing if only for this graceful habit and rich purple foliage and stems. It belongs to the small peony-flowered section, and the round, velvety crimson flowers have two rows of petals, which are touched with rose at the tips. Shown by Mr. A. J. Cobb, University College, Reading.

SHINFIELD STAR.—Although a trifle large for a star dahlia, the vivid, sparkling colour of this novelty makes it very desirable. The orange-scarlet colouring shades outwards to a rich rosy purple. Shown by Mr. A. J. Cobb.

ANSWERS TO CORRESPONDENTS

THE FLOWER GARDEN.

Colour Scheme for a Herbaceous Border (J. F.).—The primary colours are blue, red and yellow. Harmony results by shades formed by a mixture of these primary colours. Orange harmonises with red or yellow and contrasts with dark blue. The primary colours, placed together, produce a glaring effect ; this should be avoided by having softer or cooler colours between them. One example : Blue then white, pinks to vivid crimsons as a centre, with orange, pale yellow, purple and lilac, in this order, from the vivid crimsons. White may always be placed between two primary colours if other shades are not available. A herbaceous border should be planted in masses so that there will not be any big gap in the flowering season in any part of it. A good selection avoids this. Lift and replant Armeria maritima any time when the soil is not too wet.

Herbaceous Borders (J. G.).—You could not do better than have clematis and climbing roses on the wooden fence at the back of your border, but as these are not in flower till later in the year it would be well to add Early Dutch Honeysuckle, which flowers in May, and Clematis Flammula for September. For tall plants at the back of the border, the best are delphiniums, Anchusa Opal, Thalictrum flavum and T. aquilegifolium purpureum, white foxglove, Verbascum phlomoides, double perennial sunflower, and Helianthus sparsifolius (the finest of the H. rigidus class) ; white Epilobium angustifolium, Helenium striatum, Pyrethrum uliginosum, any of the Michaelmas daisies, Anemone japonica, Campanula lactiflora, hollyhocks and dahlias. Next in height will be Doronicum plantagineum, Campanula persicifolia and the good white variety of C. macrantha, phloxes, Echinops Ritro, tritoma, galega, Papaver orientale, Lychnis chalcedonica, yellow and double orange day-lilies, Œnothera Fraseri, Eryngium Oliverianum, Spiræa Ulmaria double and S. venusta, Gypsophila paniculata, flag iris in variety, especially the fine I. pallida dalmatica, montbretias, Centaurea montana, Buphthalmum salicifolium and Anthemis tinctoria. Then for plants of 2ft. and under : Geranium ibericum, Helenium pumilum and H. cupreum, Tradescantia virginica, Statice latifolia, Dicentra eximia, Rudbeckia speciosa, Doronicum austriacum, Sedum spectabile and Nepeta Mussini. For the front edge : Double arabis, aubrietia, pinks, Campanula carpatica, helianthemum, myosotis, Viola gracilis and Polygonum affine. Good kinds of phlox are : Mrs. Jenkins, white ; Coquelicot, scarlet ; Hodur, palest pink ; Mrs. Oliver, middle pink ; and Meteor, deepest pink.

Treatment of the Cape Forget-me-not (E. S.).—The young plants should be grown fully exposed till there is danger of rather severe frost and then placed in a cold frame in which they can be protected during the winter months as required. If they are to be flowered in the open border, do not re-pot ; but if in pots, then re-pot in February using a compost of loam, leaf-soil and a small quantity of well rotted manure.

TREES AND SHRUBS.

The Treatment of Yuccas (H. F. T.)—When the flowers have faded and the stem is withering, the latter should be cut off about 2ins. from its base ; then, after being allowed to shrivel up, the remainder of the stump should be pulled out. Very careful treatment will be needed in lifting and replanting the specimen to avoid damage to the roots. The work should be done now for preference, or not later than the middle of October this year.

THE ROSE GARDEN.

Rose Rust and Rose Black Spot ("Spot").—The leaves are infected with orange rose rust and black spot, respectively. As this is the end of the season, remedies need not be applied beyond the careful sweeping up and burning of all leaves as they fall or are shaken off. Next year the young shoots should be syringed with sulphide of potassium at the rate of half an ounce to a gallon of water before the rust has an opportunity to spread again, but not before the leaves are well developed. Repeat syringing once a month at a time when there are no flowers open. See also Mr. H. L. Wettern's letter on page 654.

MISCELLANEOUS.

The Use of Field Telegraph Cable (Miss D. E. L.).—The cable referred to would answer the purpose well enough and, if painted dark green, there would be no danger of harm resulting to the fruit tree branches. Galvanised wire is extensively used for this purpose. But we think that the painting of the cable wire would be an improvement and the work may be done in a very short time.

Preparing Ground for Garden Crops (Owner).—The position of the land is an ideal one, and as the ground has been under grass for two years, it will be improved on that account. A good heap of turf should be secured for potting purposes and the planting of choice fruits and shrubs in the future. All the soil devoted to fruit trees and vegetables should be trenched at least 2ft. deep, loosening the subsoil but keeping it below. The cleanest lawn and the most economical to make would be the one resultant from sowing seeds next March if the present turf is not good enough. If seeds are sown, the lawn ground should be cleaned and prepared during the autumn, but not deeply dug. Division screens between the vegetable, fruit and flower quarters may be made attractive by planting ornamental shrubs and roses on arches and trellis. Each quarter should be as bold as possible and not cut up into many little features.

Names of Plants.—G. S. F. N.—1, Lysimachia vulgaris ; 2, Lathyrus sativus ; Asplenium Adiantum nigrum.——T. N., Bucks.—Solidago missouriensis montana.——C. A. H.—Rose Coquina (Wich.).——"Limington."—Polygonum cuspidatum.——S. T.—Hemerocallis fulva var. flore plena.——C. N.—Hibiscus syriacus.

CORRESPONDENCE

BLACK SPOT ON ROSES.

SIR,—The common desire of all true garden lovers to join their forces in making known, for the benefit of all, the success of any line of attack upon ruthless and persistent diseases which ravage our gardens and destroy so much patient endeavour, is the writer's apologia for making known the following facts.

Discouraged and disheartened by repeated attacks of the insidious disease known as black spot, experiments were made with most of the remedies on the market. A substantial measure of success was only obtained with a preparation known as "Tarbol," manufactured by the Chemical Union, Limited, of Ipswich.

With this, as with all other remedies, patient and systematic applications are essential, and continued sprayings are necessary almost all the year round. The material is a strong and highly concentrated fluid disinfectant, and the greatest care must be exercised in its application, more particularly in the spring and early summer, when too strong a mixture would quickly destroy the tender young shoots and foliage.

As a result of our trials we found that not only should the plants, both stems and leaves, be thoroughly sprayed, but during the winter months the ground beneath should be sprayed continuously, to secure the extermination of dormant germs in the soil.

One word upon the results obtained: This year plants and beds treated in the manner above described are practically free from this disease, while, unfortunately, and at the same time, other beds not so treated have been attacked.

The results obtained from this germicide have been so positive and reassuring that its use is being extended, and further beds, previously untreated, are now being subjected to the process.—HERBERT L. WETTERN, *Oxted*.

ROSES IN MEADOW GRASS.

SIR,—Has your correspondent, E. F. (page 592, August 23rd), tried Rosa Moyesii? We have one about ten years old and 7ft. high. Every year it is covered with bloom and in the autumn with its beautifully coloured fruits. It has had no attention since planting (six or seven years ago), and looks quite happy and at home in the long grass, making new strong growths every year.—M. C. B.

PLANTS GROWN IN SLATE.

SIR,—It may not be generally known to your readers that a lot of reputedly difficult plants may be very successfully grown in a mixture composed largely of broken-up slates, especially some of the lime-haters. I recently procured a quantity of broken oddments of the thick green Cornish slate so seldom seen in this part of the country, and discovered that by mixing them to a proportion of two-thirds ground-up slate to one-third leaf-mould and silver sand, I was able to ensure the happiness of a number of my treasures, such as Saxifraga lilacina and some of the rarer and more difficult androsaces, and I am now about to try to grow that most tricky of all alpines, viz., Eritrichium nanum, in this compost. If the special slates cannot be easily procured (and they are rather difficult to get hold of) the ordinary housing slates will do very well mixed to about the same proportions. I think that a scree composed of this material would be a great adjunct to the garden of the keen grower and lover of these extra special treasures, and need not occupy much space or be at all expensive, as the slates may usually be obtained for the trouble of carrying them away.—W. A. Th. INGWERSEN, *Herts*.

A NATURAL ROCK AND WATER GARDEN.

SIR,—I send you this photograph which I hope may prove of interest to your readers. It represents to my mind what should be aimed at by the maker of a rock and water garden. As a matter of fact, it is an old unused country quarry away in the solitudes of County Down. It is surrounded with tall ragworts, purple knapweeds and many of the Umbelliferæ, as well as by many of the smaller bright wild flowers. The great golden heads of the ragworts cast their shadows in the water, and if this spot was planted with tall marsh-loving garden plants and aquatics no further construction would be necessary. What spoils most rock and water gardens is their formal and unnatural appearance.—WALTER SMYTH.

AN INFORMAL ROCK AND WATER GARDEN IN COUNTY DOWN.

ENGLISH ANNUALS IN KENYA COLONY.

SIR,—I see in your Editorial of April 26th that you ask for information regarding the advisability of growing English annuals in a Nairobi garden. Unfortunately, I cannot speak as one who has actually possessed a garden in Nairobi itself, but at the same time it is more than likely that flowers which do well in other parts of the Colony—at approximately the same altitude as Nairobi—should do equally well there.

Of the annuals which can be grown without any difficulty at altitudes of 5,000ft. and upwards with a reasonable rainfall, the following are probably the most prolific: Antirrhinums, larkspurs, salvias (red and blue), verbenas, cosmos, nigella, sunflowers, gypsophila, eschscholtzias, balsam, stocks, phloxes, salpiglossis, gaillardias, African marigold, nicotiana, dianthi, asters, zinnias, nasturtiums, clarkias and night-scented stock. Of this list, the first two have so far, in my own limited experience, always given the largest return and the most brilliant show.

There are, of course, many other well known annuals which do excellently in some parts of the Colony, but seem, for reasons which I cannot explain, to be a complete failure elsewhere at the same altitude and in much the same sort of soil. Aquilegias, for instance, have at times been more than easy to grow, but at others they have come to nothing beyond mere germination. Sweet peas in the same way; though with these it seems necessary to be most drastic in confining the plants to only one or two shoots—they are inclined to send out an abnormal number and to go entirely to leaf, if not so restricted. Again, lupins have done excellently at times though they seem to require a greater rainfall than is sometimes available for them.

Up to the present delphiniums and wallflowers have come to nothing, though I understand that the former have been grown with remarkable success in the really high altitudes; the latter seem to grow most healthily, but never flower (any suggestions as to how this should be dealt with would be most welcome).

In this country one is always experimenting, and this year some more English annuals are being grown in the garden for the first time. Whether or not they will be successful it is at present impossible to tell. At the moment the dimorphothecs, godetia, browallia, annual carnation, Swan River daisy, scabious, phacelia and Alyssum minimum look very healthy. It is, however, uncertain whether nemesia and lavatera will survive the shock of being bedded out towards the end of the rains.

It is unlikely that all this will be of interest to your Nairobi correspondent, but it is just possible that some of your home readers will be interested to hear that many of the flowers they love are also gladdening the eyes of those who live in what you are pleased to term "the back of beyond."—F. C. JACK, *Kenya Colony*.

ALONSOA WARSCEWICZII.

SIR,—For several years I have grown a charming form of this annual known as compacta, but never till this season have I seen it so fine. The seeds were sown in a cold frame in March, pricked off in boxes, and transferred to their flowering quarters in May, and now for the last two months a wealth of bright scarlet flowers have been on view. The plants are from 1ft. to 18ins. high, and they will continue to bloom for some weeks. The plants were never allowed to become starved, especially in the seedling stage, and it ought to be borne in mind that stunted seedlings never give such fine results as those afforded more liberal treatment. This plant is also excellent for pots; the seeds are sown in September and grown cool, the same treatment being required as given to clarkias, stocks and schizanthus.—T. W. B.

SIMPLE GARDENING

CLEANING HERBACEOUS BORDERS.

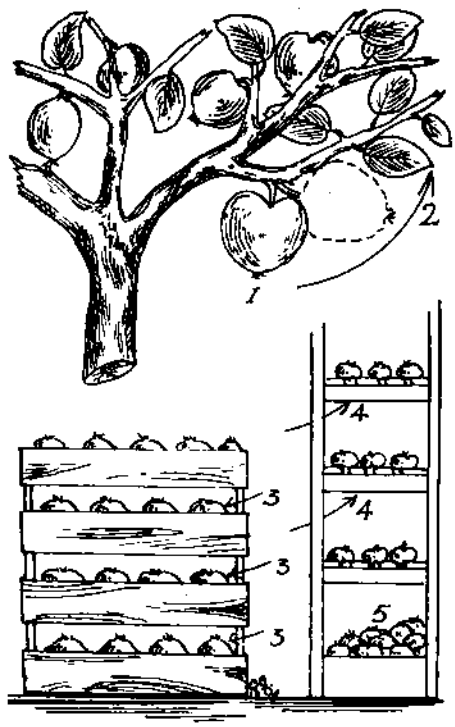
WE all know how soon a neglected garden becomes an untidy wilderness. There is no part of a garden that shows neglect more, or sooner, than the herbaceous border. I heard an amateur cultivator remark recently that he had given up, or was giving up, the growing of herbaceous plants because they entailed so much labour in maintaining the border in good condition, and, furthermore, that he intended growing roses instead. Well, I think there is room for both sections and all entail labour. Without the latter we should not value the plants as they deserve. To clean a herbaceous border thoroughly, begin the work now. Many plants in it cannot be moved every year, neither is it desirable to do this, and if we attack underground-rooting weeds, such as couch, and others that lose their leaves in the winter, we are able to trace and clear them out. Of course, it is a very easy matter to Dutch hoe the soil and rid the surface of seedling weeds, but even this work is not always timely done. But merely for the sake of tidiness do not cut off the stems of herbaceous plants prematurely; be sure that such are ripe for removal and examine closely the clumps, removing all foreign matter collected there.

PLANTS UNDER GLASS IN THE AUTUMN

Amateurs who grow plants outside during the summer months and transfer them to the greenhouse in September often find it difficult to maintain them in a good healthy condition during the dark days of winter. We should remember that the difference in atmosphere and temperature under glass is very great compared with open-air conditions from which the plants have been taken. The right thing to do, then, is to try to maintain the outside conditions for a time after the plants are placed in the greenhouse. As much air as possible should be admitted to the structure, not in the daytime only, but also at night. Very careful watering is essential as the plants are not producing many new roots, so that, practically, all that is required is the maintenance of the health of roots and leaves. The arum lily is always benefited by overhead syringings on bright days. Azaleas and similar hard-wooded plants should be placed on their sides and forcibly syringed prior to placing them under glass to get rid of insect pests, chiefly red spider and thrips. The drainage of all pots should be examined, too. Primulas, cinerarias, cyclamens and calceolarias are best placed on a bed of old coal ashes. Ashes on slates will answer the purpose equally well.

GATHERING AND STORING APPLES AND PEARS.

In some districts these fruits are good average crops, in others they are scarce. In both cases as much care as possible should be taken in carrying out the work of gathering, grading and storing. This work is not done as it should be in many parts of the country, especially that relating to grading. When the apple is raised from No. 1 to No. 2, as shown by the dotted lines, and then readily parts from the branch, it is ripe enough to gather. The fruits should be gently placed in baskets and not in



"bagged" aprons, and graded into three sizes, the finest specimens in single layers in flat-bottomed baskets. The store-room should be cool, dry and well ventilated, and not subject to sudden and extreme changes in temperature. The fruits may be laid in clean boxes, fixed one above the other so that air can reach the fruits as shown at Nos. 3, 3, 3, or in a fruit-room on lattice shelves as shown at Nos. 4, 4, those fruits for immediate use being placed at the bottom, No. 5.

HOME-MADE PROTECTORS AGAINST FROST.

It is advisable to make due provision for protecting plants in cool houses, in frames and in the open air during the winter months. Loose litter is always useful, but becomes untidy unless regularly swept up and prevented from blowing about. Straw hurdles are splendid and not difficult to make. First "draw" the straw by hand to straighten it, rejecting loose ends. Procure some light laths, lay them on the ground 1ft. apart, and then the straw neatly and evenly on them. Place top laths directly over the ones beneath the straw and with tarred twine bind top and bottom laths together so that the straw is compressed and held firmly. Trim off loose ends and very neat handy protectors will be available. All protecting material should be kept as dry as possible when not in use. Rushes, reeds, coarse grass (made into hay condition) and even evergreen branches of a close feathery nature will answer as plant protectors. Loose or short litter should not be discarded, but formed into conical-shaped heaps to ensure dryness. In due course the frosts come and not only penetrate into the frames through the glass lights but also the sides of the frames. Here we have a good use for the short litter, and it should be closely packed against the sides of each frame, about 1ft. in thickness.

PLANTING EVERGREEN SHRUBS.

Some cultivators lift and replant shrubs when it is wrong to do so, others refrain from transplanting them when a shift to another border would be beneficial both to the shrubs and the general appearance of the garden. Where it has been decided to lift and replant any evergreen shrubs, the work may be done now. Very frequently inexperienced cultivators are worried after such replantings when many leaves fall off. For the benefit of such I may say that the falling of some of the leaves is not a bad sign, the plants usually do well afterwards, But when all the leaves adhere to the stems—I may mention, in particular hollies—then frequently the plants die, the leaves turning brown but still adhering. Having decided as to the new positions, make the necessary holes large enough and thoroughly water the soil round each specimen, well saturating the roots. Begin by taking out the soil far enough from the stem, gradually working towards the stem, but leaving a reasonable quantity of soil adhering to the roots to be moved with them to the new position. The placing of the soil around the roots should be done with extra care and each specimen should be duly staked, whether in bush or tree form, in exposed positions to ensure steadiness till new roots grow. When choice, large specimens are lifted, it is a good plan to wrap flannel bands round the main stem and keep moist by syringing daily.

GEORGE GARNER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Cauliflowers.—These are coming to maturity, and to preserve the colour and protect them from slight frosts the outer leaves should be bent over the curds. Those not required for immediate use may be lifted and placed near a north wall or hedge, and the roots again covered with soil. This method will prolong the supply for a week or two.

Lifting Crops.—The time has arrived when such work will need attention, and it ought to be carried out with care. Potatoes in many gardens are the chief crop, and should be stored in a cool, dry, but frost-proof shed. Onions need to be well dried before being placed in store, and on a wet day they may be tied in small bunches and suspended from the roof. Carrots and beetroot may be laid in a bed of ashes. When lifting the latter, care should be taken in removing the leaves. A good plan is to screw them off with the hand, but if a knife is used see that the foliage is not cut too near the crown of the roots, or they will bleed and be useless. Parsnips and celery are best lifted as required.

FRUITS UNDER GLASS.

Pot Trees.—Where it is intended to grow fruit trees in pots, now is the time to make a selection. The kinds usually grown are peaches, nectarines, plums, figs, cherries and, often, apples and pears. Apricots are too generally a failure to warrant their being grown in quantity. To be a success a house should be set apart for their accommodation when the time arrives for placing them inside. It is useless to grow them in vineries and peach houses where the roof is covered with foliage. Unfortunately, in some private establishments this is done. When the various fruit trees are received they should be potted at once, using pots just large enough to take the roots; for the most part receptacles 10ins. to 12ins. in diameter will be quite large enough. Good quality fibrous loam will form the staple, to which is added a liberal sprinkling of old mortar rubble. The pots should be provided with ample drainage, and the soil made fairly firm. Place the trees in the open and see that they do not suffer from dryness at the roots. If desired established trees in pots can be bought; several fruit nurseries specialise in this particular branch.

THE HARDY FRUIT GARDEN.

Arrangements for the Future.—Now is a good time to look over the fruit plantations, and note any work that needs doing during the next few months. Some young trees may require root pruning to induce them to produce fruit buds, while trees that consistently refuse to bear fruit ought to be uprooted and replaced with a reliable kind. Fruit pergolas that have become overcrowded will need thinning and such operations can be carried out directly the leaves have fallen. In the meantime prepare a quantity of broken bricks for drainage where such is necessary and mortar rubble for mixing with the soil. Overcrowding in the fruit quarters is a great mistake. Light and air are important factors and although in winter the trees appear to have plenty of space for further development, yet when clothed with leaves much necessary light is excluded. Hence the reason for making plans now. If new trees are needed, the order ought to be sent off as soon as possible, and it is a good plan to have each tree named with a zinc label. At this season the plantations may be cleared of all weeds, and with the ground so wet in many districts, it is advisable to remove the weeds at once to the rubbish heap.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Celery.—Further tying and earthing up should be given the early plants. Among the later batches cleaning, tying, watering at the roots if need be, and earthing up should be attended to.

Spinach.—Now is a most suitable time to make sowings of the prickly variety so that good pickings will be obtained early in April.

Trenching.—When the old strawberry plants have been cut over, and cleared away or burned with the straw, the ground should be given a good dressing of farmyard manure, especially if the plants have been grown on the ground for some years. The alleys and all around the area should be properly hoed and raked and the surface weeds thus collected should be spread over the ground, and buried as the work of trenching proceeds. Ordinary trenching is fairly simple, but on heavy land or where the subsoil is very poor double digging is sometimes best. This kind of trenching allows of the good surface layer of soil being turned over but kept on top. It is quite easily done, but the uninitiated really require to be shown on the spot how to perform such work.

THE FLOWER GARDEN.

Bedding Plants.—It is not safe to leave boxes or pots filled with such plants as ageratum, geraniums and heliotrope, etc., in the open. The plants should be cleared of all decayed leaves and extraneous matter, while the base of the boxes and pots should be examined to make certain that no slugs are hidden underneath. The boxes should be placed in frames or into some of the houses from which the fruit has been cleared. Such bedding plants do not require heat meantime, but they should be set where frost will not reach them.

Herbaceous Borders.—On borders where no renovations are taking place weeds will require to be kept in check by hoeing and hand weeding, while plants which have passed out of flower should be partly cut over, especially if they have grown above the stakes and are hanging over, or appear in any way untidy. Verges on lawns and around flower beds should be kept cut, and now that tinted autumn leaves are falling, lawns and walks will require occasionally to be swept clear of them, so that everything is kept in trim order. Long grass in and around the shrubberies should be cut with the scythe so that leaves will be more easily raked and cleared throughout the winter months.

Lilies of the Valley.—This is the time to proceed with the planting of these roots, or with the digging up of old and crowded beds. Oft-times lily of the valley beds get overrun with perennial weeds, such as bishop's weed or couch grass. If these roots get established in the ground, nothing can be done to clean the beds properly except digging everything up. The lily roots should be picked out and cleared of all weeds, then replanted on clean ground, which has been well manured and previously cropped. The plants should be set 2ins. or 3ins. distant from each other in lines 8ins. or 9ins. apart with the points of the crowns very little below the ground level.

FRUITS UNDER GLASS.

Vines.—The rods of the intermediate house should have the side growths cut back leaving 8ins. or so of wood to be pruned later when the vines are dormant.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.)
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Liliums.—The first consignments of Lilium longiflorum are now on the market, the variety offered being L. longiflorum var. formosanum: the variety Harrissii that used to be so largely grown being seldom offered now, although I understand that the industry in the Bermudas is now in a position again to supply healthy stock. Lilies when received should be unpacked at once and carefully sorted over, any decayed scales being removed. As lilium bulbs suffer quickly from exposure to the air, they should be potted up at once. If for any reason this cannot be done, they should be laid in boxes and covered with leaf-soil or some such material to keep the bulbs fresh and plump. The potting compost should consist of a good medium loam, with the addition of a little well decayed leaf-soil and sand. According to requirements the bulbs may be placed singly in 48-sized pots, or three or four in 6in. or 7in. pots. As Lilium longiflorum is a stem-rooting species, the bulbs should be placed well down in the pots, to allow room for the development of stem roots. When potting, room may be left for adding a top-dressing later on, or the pots may be filled right up at the time of potting. After potting they should be stood in a cool greenhouse or cold frame, very little water being given until they have made a quantity of new roots, when they may be introduced to a higher temperature for forcing purposes. If it is not desired to force them, they may be allowed to come on gradually in an ordinary greenhouse temperature. Lilium speciosum, L. auratum and their varieties will not, of course, be available for some time yet, but when on hand they should be given the same treatment as advised for L. longiflorum; but as a rule they will require larger pots. Healthy plants of L. auratum and L. speciosum that have been used in the conservatory should not be neglected, as they are often at their best the second year. At present they may be stood outdoors at the bottom of a wall; later on, when the stems have died down, they may be given the shelter of a cold frame or may be plunged in ashes outdoors. When starting them next year, if in good condition at the root, re-potting should not be necessary, but a portion of the top soil should be removed and be replaced with a top-dressing.

Sweet Peas may now be sown in cold frames, in pots or boxes according to the quantity required. If intended for growing throughout in pots, four or five seeds may be sown directly into large sixties or 48-sized pots. The seed pots should be filled with a compost of good loam with enough sand to keep the whole open and porous. Leaf-soil is not necessary unless the loam is heavy. The soil should be made fairly firm in the pots. Stand the pots in a cold frame and keep them shaded until germination takes place. They must also be guarded against attacks from mice, either by covering the pots or seed boxes with pieces of glass, or dressing the seeds with red lead before sowing. This latter method is a very useful precautionary measure and should be borne in mind. After germination takes place the plants should be given plenty of air on every possible occasion, pulling the frame lights off whenever the weather permits, as the chief object is to keep the plants as strong and sturdy as possible during the winter. The plants may be kept to a single stem or, if so desired, the young plants may be pinched and several shoots taken up.

BOOK REVIEW

AN exceedingly valuable little booklet has been issued for the London County Council on their activities in London parks and open spaces. ("London Parks and Open Spaces," University of London Press, 1924, 1s. net.) In 1855 only nine parks were under control of H.M. Office of Works, and of these only one was in the poor and crowded East End. On March 31st, 1924, the L.C.C. had 117 parks, gardens, churchyards and open spaces of 5,183 acres under their control, with a permanent outdoor staff of 1,161 and an annual cost of maintenance of £300,000, surely an enormous and a worthy increase.

This little volume, which consists of 115 pages, describes each park or open space in detail, with additional paragraphs on subjects like animal and bird life, bands, bathing, games, fountains and statues. It is well illustrated throughout and there is a useful map at the end. We can heartily recommend this work to all who are interested in their London.

To Iris Growers and Breeders.—All iris growers and breeders are requested to forward at once their varieties of 1923 and 1924 introduction to the Head Gardener, New York Botanical Garden, Bronx Park, New York City. The plants received will be planted under number and become eligible for judging in 1926. Upon request all increase will be returned to the donor. A silver medal and five awards of merit are available for distribution among varieties introduced each year and certified numbers will be assigned other less worthy introductions. The Garden Club of America offers the first medal for the finest variety introduced in 1923, an American Iris Society medal is offered for the finest variety introduced in 1924. The two year period gives the plant time to become well established. The awards are few and will be given wide publicity. It is to the interest of the introducer to secure such official recognition for a variety and to the interest of the amateur gardener to take advantage of these recommendations. Foreign growers may import under permit from the New York Botanical Garden, but must bear all costs of duty and transportation.

Horticulture at Wembley.—One of the brightest and most restful spots in the huge area covered by the British Empire Exhibition is that of the section devoted to the horticultural exhibits. Within this section is to be found a plot of which the purpose is to keep in memory those who fell in the great war. The idea was conceived and later organised by a body known as the Circle of Hope. This plot is now known as the "Garden of Remembrance," and may be continued for a longer period than the Exhibition, if circumstances permit. Messrs. Geo. Jackman and Son, of Woking Nurseries, Surrey, whose exhibit is to the forefront, well arranged and excellently displayed, appealing to the artistic eye, readily gave their support to this movement and now visitors may easily find this particular plot dedicated to the fallen. Within the exhibit is to be found a small pavilion, well designed and built of stone, while the surroundings set it off to distinct advantage.

Importation of Plants into Canada.—The Ministry of Agriculture and Fisheries desires to inform exporters of plants that the Canadian authorities have issued an Order, which comes into force on October 1st, 1924, prohibiting the importation of merchandise packed in hay, straw or other fodder from all countries other than the United States. Exporters should, therefore, arrange to [illegible] other forms of packing material [illegible] consignments to be sent to Canada.

The Gardeners' Royal Benevolent Institution.—The Prince of Wales [illegible] promised to preside at the seventy-ninth anniversary festival dinner in aid of the funds of the Gardeners' Royal Benevolent Institution on November 25th next.

THE GARDEN

ORCHARD GARDEN WOODLAND

Vol. LXXXVIII.—No. 2758 Saturday, September 27th, 1924 Price THREEPENCE

The Kelway Colour Border

The formation of actual scenes of beauty with living subjects abounding in interest individually would seem to be a pleasant and worthy amusement, and one as full of dignity as the portrayal of such scenes on paper or canvas.

The late Dean Hole truthfully wrote in *Our Gardens :* "There has been no introduction which has had such happy and universal influence in extending and increasing the enjoyment of a garden as the HERBACEOUS BORDER." One of the first remarks of one's hostess in the country nowadays is, "Would you care to see my new Herbaceous Border ?"—or "my new KELWAY Border ?"

Send dimensions of space to be filled, and the effect required, stating aspect and soil, and asking any questions.

WRITE NOW to the inventors of Colour Borders :

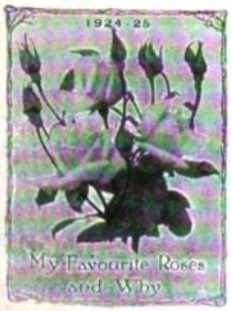
Also List of NEW HYBRID NERINES, the most beautiful Autumn-flowering plants for the cool greenhouse

BARR & SONS, 11, 12 & 13, KING STREET, COVENT GARDEN, LONDON, W.C.2.

You will, I hope, forgive my questionable method of arresting your attention. The question itself is really one of moment to you.

Do You know this Booklet ?



If you know it, there is no question at all about it ; you send for your copy every year and wouldn't settle your new list without it.

"MY FAVOURITE ROSES AND WHY" is a text book to give any beginner confidence, but it aims to be a YEAR BOOK and a ROSE ANNUAL that will keep an expert up to date.

Of course it is a Catalogue, too—it wouldn't be free and post free if it weren't ; but don't hesitate to write for it because you can never send me an order—if I may say so—it isn't your order I'm after, it is your appreciation.

THE GARDEN

VOL. LXXXVIII.—NO. 2758. SEPTEMBER 27, 1924.

RHODODENDRON LODERI, THE FINEST HYBRID RHODODENDRON IN EXISTENCE, AND IN THE OPINION OF MANY ONE OF THE BEST OF ALL FLOWERING SHRUBS. ALTHOUGH IT SURVIVES IN THE NORTH IT ONLY GROWS TO ITS FULL LUXURIANCE IN THE SOUTH AND WEST OF ENGLAND.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

PLEASE REMEMBER TO MENTION "THE GARDEN" WHEN ANSWERING ADVERTISEMENTS.

IDENTIFICATION OF PLANTS

IN this issue will be found a letter from Mr. Laurence J. Cook in reply to one from Dr. P. A. Hendley in the issue of September 13th on the Purpose of Wisley. Mr. Cook does not mention Dr. Hendley's main theme, but confines himself to attacking Dr. Hendley's strictures on the correct naming of plants in catalogues and elsewhere. It is not our policy to interfere in a debate between correspondents, but this appears to me to be an exceptional case, for neither of the correspondents—one a well known amateur and the other an important member of the trade—appears to realise the difficulties which beset both the trade and amateurs over the correct naming of plants.

It is, perhaps, easiest to tabulate a few of these difficulties:

A.—IDENTIFICATION OF SPECIES.

(1) The internationalism of botany. Herbariums exist all over the world and no herbarium is complete; therefore it is next to impossible to avoid duplication of names. Dr. Handel Marzetti, an Austrian, may have collected a new meconopsis in China. It is named in Vienna. Mr. Forrest may find the same plant, which is sent to Edinburgh. With no published description of Dr. Marzetti's plant, Edinburgh are unaware of its existence: therefore, for several years the plant is saddled with two names. This has happened not once but many times in the history of plants.

(2) The different methods of systematic botany in use in various parts of the world. There is no real standard or rules upon which botanists can work. Germans and Americans are inclined to split species on the slightest variation in the structural form of the plant, with a consequent multiplication of names. This, of course, makes the correct identification of many genera—*i.e.*, rubus and cratægus—of extreme difficulty.

(3) The fact that a botanist overlooks an old plant and inadvertently gives the same plant a new name when collected many years after. Rhododendrons Kyawi and facetum are cases in point.

(4) The difference in the juvenile and adult appearance of the plant.

(5) The variation in form of a species which is not entirely fixed; *i.e.*, that it varies slightly according to the locality in which it is found. This also applies to plants which differ slightly from the type when transported to our gardens.

B.—GARDEN VARIETIES.

(1) The fact that many genera—*i.e.*, berberis, saxifraga, etc.—cross naturally on the slightest possible occasion. Indiscriminate sowing of this seed causes innumerable forms to appear.

(2) The difficulty of definitely deciding if a plant is a species or a hybrid.

(3) The fact that many hybridisers are trying to effect results from crossing the same strains. This is bound to cause duplication in many cases.

(4) The indiscriminate hybridising and naming of hybrids, carried on alike by the trade and by amateurs, which causes a multiplication of names often not justified by the worth of the plant.

(5) The keenness to place new hybrids in general cultivation at the earliest opportunity with fancy names attached, before their worth has been proved.

These are only a few of the difficulties attached to identification of plants, but they are sufficient to show how hard it is to keep plants in a garden correctly named. Dr. Hendley, perhaps, forgets all the troubles and tribulations over correct nomenclature with which the trade has to contend. Mr. Cook, on the other hand, is inclined to gloss over the fact that, although names are important for the amateur, they are doubly so for the nurserymen through whom most of the plants in our gardens are obtained.

One concrete example came to my notice in my own garden. A larch arrived, carefully labelled "Larix davurica japonica." There was no mark of a cross on it. There is a Larix davurica and a Larix japonica, otherwise leptolepis—entirely different species. In order to find out which it is I have to wait until it is old enough for identification: surely an unnecessary waste of time.

E. H. M. C.

ANTIRRHINUMS

THE DAY OF THE NAME "SNAPDRAGON" IS PAST AND "ANTIRRHINUM" HAS TAKEN ITS PLACE, BUT THIS GARDEN FLOWER STILL RETAINS ITS POPULARITY.

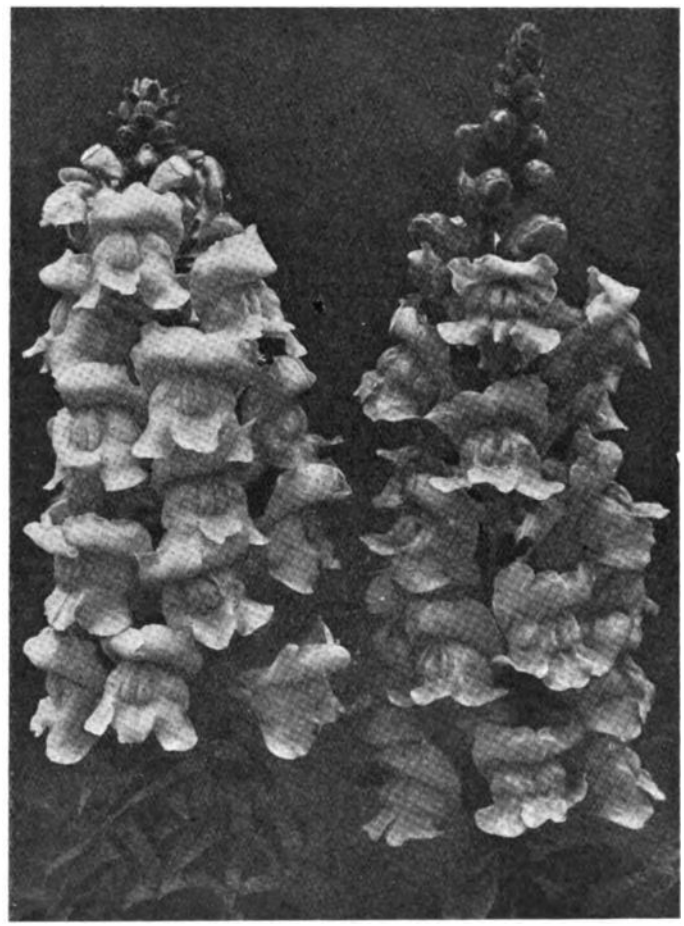
THE time is ripe for a review of the progress that has been made with antirrhinums, and for consideration of the future prospects of the flower. It would be just vapid inanity to make general declaration that the antirrhinum has made vast strides, etc., for readers of THE GARDEN are fully conversant with that obvious fact. The production of new varieties has proceeded apace, and the planting of antirrhinums has extended to well-nigh all British gardens, but—to express entire satisfaction with the trend of things as concerning antirrhinums would simply reveal the outcome of a superficial survey rather than careful investigation. The progress made has not been as directly forward as it could and should be, for it has not been as great as the plant deserves.

The greatest handicap to the straightforward march of progress has, thus far, been an undue prevalence of mediocrity in stocks which ought not, in view of the existence of superior stocks, to be grown at all.

Superb varieties are plentiful, and as distributed by raisers and specialists are fine in every way, but to keep a stock of an antirrhinum at high-water mark is a task for the constant care of experts, and many a first-class stock, having got into inexperienced hands, has deteriorated until it bears small resemblance to the variety whose name it carries. The obvious safeguard against disappointment from this cause is to be careful to obtain seed only from real specialists.

Further disappointments are far too commonly the result of faulty treatment of young plants. Thousands upon thousands of antirrhinum seedlings are distributed which, for the sake of cheapness, are treated in a manner that destroys their chances of real success. The antirrhinum is so tenacious of life and so eager to produce bloom that, despite many hardships endured, it will struggle into bloom, but the best it can give is miserably poor as compared with the production of a plant that has been carefully and well grown from germination onward. There are no intricate mysteries in regard to the raising of good antirrhinum plants; it is simply a matter of rational treatment and watchful care. It must be patent to all that under existing conditions no plants can on any nursery be granted continuous, watchful care unless a reasonable price can be realised for them, and to hanker after the lowest possible price must inevitably mean the sacrifice of quality. Even the best of antirrhinums may be obtained at far lower cost than many other plants which give far less return in the way of flowers, and it is no exaggeration to say a dozen really fine antirrhinums are infinitely better than a hundred spindly, starved and indifferent plants. Nevertheless, it is the latter which have been allowed to hamper the pace of progress of one of the most remarkable floral developments of our time.

The present is an opportune moment to discuss methods of raising antirrhinums, for it is the season for autumn sowing, and autumn-sown antirrhinums are far and away the best.



FOR BEAUTY THE FINE SPIKES OF ANTIRRHINUMS ARE DIFFICULT TO BEAT.

Permit just one reiteration of the importance of securing a reliable *stock* as well as a pleasing variety, for without the best seed labour will be futile.

Where to sow is the first question. In more gardens than is generally supposed September-sown antirrhinums would be better in the open than under cover. October is too late to be safe except in specially favoured gardens on very porous soil.

One of the dangers which menace the future well-being of the antirrhinum is the tendency to coddle it and to grow it to a far greater extent than is good for its naturally hardy constitution under glass.

There are places where antirrhinums perish in winter, and these are not generally the places where frosts are keen, but where soil is wet and plastic, where atmosphere is prone to be humid and stagnant, and where, as around London and manufacturing towns, the foliage becomes coated over with grime and sooty deposits. Where such conditions prevail it is wise to make up a seed-bed in a cold frame, but it is not wise to sow in an artificially heated greenhouse. Whether in the open ground or in a frame, the seed-bed should be made firm. Antirrhinums cannot grow well in loose or spongy soil. It is not a good plan to manure a seed-bed freshly, especially in autumn.

Sow the seed very thinly in rows, allowing what distance between the rows area will permit, 6ins. being better than less because it admits of a small Dutch hoe being run between the rows. The seed requires no more than ⅛in. of soil covering, and it will be an advantage if a liberal dressing of coarse sand has been previously raked into the surface. The plants may remain in the seed rows through winter.

If circumstances necessitate sowing in boxes, see that these are 3ins. deep. Provide plenty of drainage holes and place 1in. of rough porous material over the bottom of the box before filling in with an ordinary potting mixture of a rather sandy character. Make the soil perfectly firm and sow the seeds very thinly. It is a good plan to keep the seed-boxes in the open during good weather, only placing under cover when inclemencies necessitate.

The choice of varieties is essentially a matter of personal preference, and the range is ample to meet all tastes. It may, however, be of some assistance to describe a few which possess merits in the way of form and habit as well as colour.

The brilliant fiery shades are universally popular, and of these Flame is one of the finest. I recently saw a wonderful plantation of this variety which had been reselected to a point of perfection, and in all respects it is remarkable. The pips and spikes are good, the colour intense, and the plants beautifully symmetrical.

Exquisite is a novelty, and is a very delightful flower. The colour is of the shade of pink closely associated with

Digitized by Google

perpetual-flowering carnations, and the spikes are of superb form. It is a variety of which large masses should be planted.

Eclipse will delight the lovers of a rich velvety crimson. The colour is brighter than either Empress or Monarch, but the last named will still hold its own as one of the very finest of the really tall antirrhinums. The spike is of remarkable length, and the individual flowers are models of form and of great size.

Silver Queen commands attention by reason of its exceptional size and form of flower and beautifully built spike. Its unusual shade of mauve with a silvery sheen is decidedly attractive, but it must be admitted that the magenta tint which flushes the tube has robbed it of much affection.

The Fawn and Prima Donna have not yet been surpassed in their particularly fascinating apricot and peach tints so subtly suffused. The former excels in individual bloom, but the latter bears the finer spikes and makes the sturdiest plant.

Rembrandt, if it can be still obtained true, is a wonder for colour effect. The flaming scarlet and orange gleam proved irresistible, but I fear it is one of the varieties doomed to annihilation through careless distribution of impure stocks.

We have made no wonderful advancement in good self yellows nor in clear bright pinks. For some reason the white tube seems well-nigh inseparable from a real pink, and there is room for the clear self pink of reasonable height, or even a very tall one.

Purity and The Bride are both good bedding whites, but a pure white equal in size and stature to Monarch would be a very welcome addition, the tallest at present being the old favourite Queen of the North, which is rather small in pip and frequently gappy in the arrangement of flowers on the spike.

Torchlight is good as a tall flame-coloured variety, and its long, erect spikes fully justify its name.

The future of the antirrhinum is full of possibilities, but there are also pitfalls which its guardians must be careful to avoid. The rigorous reselection of stocks must be untiringly persisted in, and those who have good stocks must spread abroad the information, for otherwise the buyers are at a loss to know where safety lies. Much more energy and enterprise are necessary in the exhibition of antirrhinums. Only a very small number of trade specialists stage exhibits that can be credited with helping to popularise the flower, and unlike the sweet pea specialists who in the younger days of the vogue helped to encourage amateur exhibitors by putting up some attractive prizes for competition, the antirrhinum specialists have held their hand and relied too much upon popularising their flower by its cheapness.

I am no advocate of steep sensational prices for improved varieties, but I am positive the improvement of stocks and the production of healthy, sturdy plants for distribution will be met with cheerful readiness on the part of buyers to pay fair prices for good value.

The remaining danger which must be carefully guarded against is allowing the hardy robust constitution of the antirrhinum to be undermined until it falls a prey to destructive disease.

As already remarked, coddling is a mistake, and unnecessary. Give the antirrhinum as little greenhouse culture as possible. Feed systematically and judiciously, adopting the use of organic manures rather than chemicals, except that carefully chosen chemicals may be used in conjunction with natural manures to stimulate and hasten development—this being the legitimate use of wisely selected chemicals.

Some disease does occasionally afflict antirrhinums, and it is of urgent importance that prompt and drastic action be taken immediately upon the first appearance of collapse in a plant. Never leave a withering plant on the offchance of its recovery; in that way lies danger of the spread of a serious scourge. Uproot and burn the first collapsing plant discerned.

A. J. MACSELF.

NEW ZEALAND PLANTS FOR THE BRITISH ISLES

BY DR. L. COCKAYNE, F.R.S.

IN THIS FINAL PORTION DR. COCKAYNE DEALS, AMONG OTHER PLANTS, WITH OLEARIAS AND VERONICAS, WHICH ARE AMONG THE MOST POPULAR OF NEW ZEALAND PLANTS IN OUR GARDENS.

(Continued from page 647.)

5. Cyathodes Colensoi (2,000–5,000ft., dry stony ground in full sunshine) forms wiry mats, or open cushions, with short, stiff, brownish leaves, numerous small white heath-like flowers and white or claret-coloured drupes. C. empetrifolia (sea-level in south to 5,000ft., sphagnum bog or wet peat) makes small, reddish, heath-like mats bearing abundant red drupes.

6. Dacrydium laxifolium (pygmy pine; sea-level in Stewart Island to 4,000ft. in the South and North Islands; wet ground, sphagnum bog, or even dry pumice) is somewhat heath-like, and forms greyish, dense mats or straggles over low shrubs. It is perhaps curious rather than beautiful, but its striking contrast to its near relative, the yew, or to its *confrères*, the massive timber trees of New Zealand, will certainly make it a desirable acquisition for many.

VERONICAS, CORDYLINE AUSTRALIS AND PHORMIUM TENAX IN THE AUTHOR'S GARDEN IN NEW ZEALAND.

7. Dacrophyllum Menziesii (3,000–5,000ft., in sub-alpine scrub in an excessively wet climate) is a beautiful and strange-looking miniature tree, 1ft. to 3ft. high, with a short, rigid, slender stem, crowned by a rosette of stiff, sword-like, reflexed, reddish leaves with long, tapering points. It is rather difficult to procure and to establish, and its growth is painfully slow.

8. Gaultheria.—G. oppositifolia (sea-level to 3,000ft.; dry pumice) when in full bloom resembles a shrubby lily of the valley

Digitized by Google

It may attain a height of 6ft. G. rupestris (almost sea-level to 7,000ft.; rock, sub-alpine and river-bed scrub), almost as beautiful, is a small tree where the climate is extremely wet, but a shrub 1in. or 2ins. high in the alpine belt. G. depressa (snowberry; lowlands to 4,000ft., generally wettish ground or sphagnum bog) forms low dark-coloured mats, bearing a profusion of big, showy, milk-white, succulent berries.

9. Gaya (Plagianthus).—The showy G. Lyallii (mountain ribbonwood; lowlands in very wet localities to 4,500ft., low forest on stony ground, sub-alpine scrub), a small tree of rapid growth, has been figured more than once in the gardening Press, but its near relative, G. ribifolia, an equally beautiful tree, which grows naturally under far drier conditions, is less known. Its leaves are somewhat hoary and not drawn out into long points; the seeds are frequently much damaged by some insect.

10. Helichrysum coralloides (the coral shrub; 3,000–6,000ft., sunny or shady rocks in the drier mountains) has rather thick shoots after the manner of a whipcord veronica, but the leaves are reduced to glossy, green tubercles, separated from one another by closely matted white hairs. When established it is a striking shrub of unusual appearance which cannot fail to attract attention. The seedling with its flat, rather large, woolly leaves is most distinct from the adult. H. Selago is similar, but with more slender shoots, and in the allied H. microphylla they are more slender again.

11. Leucopogon Fraseri (sea-level to 6,000ft; dry stony ground, rock).—This tiny epacrid, a few inches high at most, which spreads by its underground stems, is worth growing on account of its small white flowers, its general appearance and its yellow drupes.

12. Muehlenbeckia axillaris (sea-level to 5,000ft., stony ground, rock) is quite a good mat plant for covering bare, rather dry parts of the rock garden.

13. Olearia (tree daisy).—This genus consists in New Zealand of forty-one high-class garden shrubs belonging to four distinct classes. The species with great flower-heads, the discs purple and the spreading rays white (purple in O. semidentata) and thick, more or less lanceolate, toothed leaves, white beneath, are noble plants, but, unfortunately, not hardy enough for general cultivation. The high mountain species of the genus, however, are far hardier. Of these O. Haastii, rare enough as a wild plant, is the commonest in British gardens. O. lacunosa, with narrow leaves, 6ins. long, clothed beneath with a dense mat of rust-coloured hairs, is a most striking shrub. Still more remarkable is O. Crosby Smithiana, of somewhat similar appearance, but with far narrower leaves; and then there is O. excorticata with leaves wider than those of O. lacunosa. O. moschata resembles O. Haastii, but the leaves are almost white on both surfaces. O. lineata is of a different class from any of the genus in general cultivation. It is an extremely graceful small tree with semi-weeping, twiggy branches, bearing abundance of extremely narrow, small, soft leaves and innumerable sweet-scented flowers. Dry, poor soil suits it perfectly. Perhaps the most effective olearia for garden purposes is O. arborescens (syn. O. nitida) with its beautiful, ovate, toothed leaves, satiny white beneath, and its huge masses of small white flower-heads.

14. Pimelea.—The fifteen species of this genus, with their showy, daphne-like blossoms, are all excellent garden shrubs, but perhaps the finest is P. Gnidia var. pulchella. The charming P. aridula (syn. P. Lyallii var. sericea), in form greatly resembling Veronica Traversii with small silky white leaves, grows naturally in the most arid sitations New Zealand can offer. For the rock garden the small, erect P. Traversii, the rather taller P. buxifolia, the prostrate P. prostrata (syn. P. lævigata), the mat-forming P. Lyalli (coastal only) and the extremely hairy cushion plant, P. sericeo-villosa, are eminently suitable. It may be pointed out with regard to pimeleas in general that seed in any quantity takes a long time to collect. The species are almost diœcious and the males the most showy.

15. Rubus parvus (almost sea-level to 3,000ft.) is a first-class carpet plant with long, trailing and rooting slender twigs, narrow leaves, 2ins. long, of many colours, but generally more or less bronzy, and very large red fruits. The supposed hybrid R. Barkeri, with broader compound leaves, is a still fine foliage plant. Unfortunately, it is only half-hardy.

OLEARIAS AND SENECIOS IN THE QUEENSTOWN PUBLIC GARDENS

OLEARIA TRAILLII, A HYBRID BETWEEN O. ANGUSTIFOLIA AND O. COLENSOI.

Digitized by Google

16. Senecio (shrub groundsel).—All the nineteen shrubby species are excellent. S. cassinioides (2,000–4,000ft., sub-alpine scrub), with small, strongly aromatic, narrow green leaves, whitish yellow beneath, one mass of golden yellow when in full bloom, is gorgeous. The recently discovered S. Spedeni, a near relative to the above, is a most welcome addition to the garden flora. Other species of high excellence are the small SS. lapidosus, Monroi and compactus.

Veronica (Hebe).—To deal satisfactorily with the New Zealand members of veronica or hebe, call them which you will—I am now using hebe in scientific writings—would require more space than has already been filled in these articles. The names as used in gardens, both here and in the British Isles, are in a state of wild confusion, nor is this surprising when no two botanical taxonomists are agreed as to the limitations of the species, and when amateurs add to the muddle by distributing plants under names, sometimes unpublished, sometimes most incorrect. Many so-called "species," again, are collections of different true-breeding forms, their hybrids and hybrids with other species (*e.g.*, VV. salicifolia, buxifolia, pinguifolia, Buchanani, monticola). Evidently there are frequently several different plants suitable for gardens called by the one comprehensive name. Baron von Mueller once upon a time got over the difficulty of veronica nomenclature by lumping all together under the comprehensive name V. Forsteri! There are many absurdities of this character—but none quite so great—in floras generally; every gardener encounters such daily. Here I deal only with a few species out of many rare or unknown to the gardens of the British Isles.

Veronica annulata (3,000–5,000ft., on dry rock faces) is a whipcord veronica, 6ins. high, or rather more, with its very slender, short, pale green shoots (round in cross section) arranged in four rows on the sides of the main stem, and with minute, obtuse, scale-like leaves. V. Poppelwellii is another dwarf whipcord veronica, but its shoots are square in cross section and the leaves triangular, darker green and marked with parallel veins. The whipcord veronicas and those with glaucous leaves are the most hardy. Of the latter there are many distinct forms belonging to that elastic group V. pinguifolia, of which there is no type, for Hooker included in his original description a number of different plants (*e.g.*, the "species" as originally defined is "4ins. to 4ft." high and "erect or decumbent"). So in seed of veronica sent from New Zealand there is no telling what may come forth, and so with seeds of all the "variable species" of floras. V. pimeleoides var. minor (quite different from V. pimeleoides of floras which is almost certainly not that species) is a prostrate, quite small plant with glaucous leaves and charming blue flowers. V. Biggarii, another prostrate, glaucous-leaved species, produces abundant racemes of rather small, white flowers.

I hardly dare to suggest for British gardens the exquisite, rather straggling blue V. Benthami of the Lord Auckland group, since, like its sub-antarctic companions, it is hard to come by and perhaps equally hard to grow. But the related V. Raoulii (1,000–3,000ft., dry rocks) with its elegant, oblong-spathulate leaves, margined with red, ¾in. long, and corymbs of pretty pinkish flowers, quite pink in the bud, is both procurable and readily grown. So, too, with the dainty V. Lavaudiana, another rock dweller, but it is less hardy.

An excellent method of using our shrubby veronicas for the rock garden is to root cuttings of the flowering shoots (nearly all strike as readily as willows), large enough for planting out the succeeding year, when they will bloom. In this way all the less hardy species may be pressed into garden service anywhere. All that is wanted is a constant supply of cuttings and a place to winter them where the frost will not exceed, say, 6° F.

But why be content with circumventing the decrees of Nature? Rather coax her to our will and by aid of crossing raise veronicas far more hardy and with richer colours. So, too, with the species of these genera common to the Northern Hemisphere and New Zealand—*e.g.*, ranunculus, myosotis gentiana—working principally in the direction of hardiness and colours other than white and yellow, and so in time a hardy, easily grown race of mountain lilies and golden yellow forget-me-nots might grace the rock gardens of the British Isles. But when all is said and done, is not Nature the supreme artist, and her wild flowers—children of a primeval world—should they not be the best beloved of garden plants?

GARDEN FOLK-LORE: THE DOCTRINE OF SIGNATURES

BY F. A. HAMPTON, M.B.

Omnes herbæ, flores et arbores aliaque e terra provenienta sunt libri et signa magica ab immensa Dei misericordia communicata.—OSWALD CROLLIUS.

All herbs, flowers, trees and other things that come out of the earth are books and magic emblems given us by the infinite charity of God.

THE belief that the form or habit of a plant affords an indication of its use and virtues is a commonplace of folk-medicine and examples may easily be found from the earliest times to the present day; thus Galen recommends the yellow juice of the greater celandine as a cure for jaundice (and not long ago a French physician advocated carrots for the same purpose), and Albertus Magnus in the thirteenth century recommends the flowers of the almond tree "against inflammation of the subtle humours in the Spring time" because the leafless twigs burst into such abundance of flower at the very beginning of spring.

In the sixteenth century this belief crystallised into the Doctrine of Signatures, with Gian Battista della Porta of Naples, encyclopædist and writer of comedies, and Oswald Crollius, Court Physician to Prince Christian of Anhalt, as its chief expositors. The two men were very different, almost opposite, in character, della Porta specialised in the marvellous, and the encyclopædia that he wrote, it is said at the age of fifteen, is a farrago of fantastic recipes and incredible phenomena. His introduction to a late edition is a masterpiece of self-glorification and contains the very disingenuous warning that his directions for the more remarkable experiments, such as the transmutation of metals, etc., are purposely given obscurely so that they may not be understood by unworthy persons. In the doctrine of signatures he found a congenial field in which to exploit the marvellous and indulge an exuberance of mysticism; on the other hand, to the quiet piety of Oswald Crollius it seemed a reasonable example of the providence of God—that for every ailment there should be a remedy and that remedy stamped with the indications for its use. The doctrine, in a highly mystical elaboration, formed an integral but only subsidiary part of the philosophy of the great Bombastes Parcelsus, though it is with his name that it is chiefly associated.

The essence of the doctrine was the conception of a mystic correspondence between man and the world in which he lived, using the old philosophic language, man was the microcosm, the little world, in whom the whole universe (the macrocosm), with all its parts and phenomena, was represented. Thus, the heart shape of the leaves of the trefoil was not only a "signature," or label, to be read "this is a remedy for heart-disease," but was an indication that both the plant and the human heart were of the same essential nature and were, in consequence, clothed with the same form by Archeus, the quickening World-Spirit.

In the light of this theory the chief task of pharmacy lay in the discovery and right interpretation of the signatures, which might represent either a part of the body or the disease for which the plant was specific; and here a great deal of ingenuity came into play. Crollius saw in the walnut "the whole signature of the head": the green rind represented the scalp, the shell represented the skull, the convoluted kernel the brain and the skin covering it the meninges. Preparations of the rind, shell, etc., were therefore to be used for wounds or diseases of corresponding parts of the head.

St. John's Wort was sovereign against night terrors, for "just as the sun of Heaven drives away by its light all evil spirits that delight in darkness, so Hypericon, which is to be reckoned chief among all herbs of the sun and is called by Paracelsus 'Sol Terrestris,' gives proof of the same power." St. John's Wort, putting out its wealth of miniature suns about the time of the summer solstice, probably played a part in the midsummer rites and was transferred to St. John, together with the bonfires and the feast, when the cult was taken over by the Church.

That the roots of the comfrey were brittle but quick-growing was an indication that they were to be used (as,

Digitized by Google

indeed, they always had been) for the treatment of wounds and of broken bones. Here, it is interesting to recall that when an investigation was being made, some few years before the war, of certain substances that were believed to have the property of promoting cell-division, it was found that one of the most active was allantoin, a compound that occurs in considerable quantities in comfrey root, and a preparation of it had a short vogue in the treatment of indolent ulcers.

Many other examples might be given, and they will all appear equally fantastic to our modern way of thought; but if we are to gain any inkling of how this doctrine of signatures could be accepted among men whom we cannot reasonably suppose to have been less intelligent than ourselves, we must remember that it is the product of a mode of thought widely different from our own, but very characteristic of primitive mentality the whole world over. To the primitive mind a phenomenon does not appear as the end result of a train of events leading up to it, but the interest is focussed upon the *setting* in which it occurs: the world is seen, as it were, in parallel rather than in series, and coincidences assume a supreme importance. Hence the fact that a walnut "shows the whole signature of the head" strikes the observer as a conjunction full of meaning.

We must remember that primitive man does not regard himself as an entity, cut off and distinct from the world in which he lives. His life is bound up with that of his crops and his cattle and his quarry in a deeper sense than the metaphor implies, for he has a feeling of a mystic participation with them, and the idea of a *rapport* between himself and, let us say, a herb like the mandrake is by no means incongruous with his habitual mode of thought. It is difficult to understand how these magic beliefs survived for so long the test of experience, until we realise that magic beliefs are not the creation of an individual mind but collective ideas that, in the primitive, supplant his own judgment and are accepted by him as rather more valid than the evidence of his own eyes.

Though we have abandoned the old way of thinking as a general guiding line we have not altogether outgrown it, and it is not very difficult to discover evidence of its lively existence to-day. Hilderic Friend, in his book on the folk-lore of plants, tells of a farmer who assured him that the sage in his garden flourished or dwindled as the affairs of the farm went well or ill, and a rather pretty example of the mystic bond (though here man himself is not concerned) occurs in the belief of the French wine-growers that when the vines begin to shoot in the spring a sympathetic quickening—a kind of quasi-fermentation—takes place in the wine of former vintages in cask and bottle. This belief must be almost as old as wine-making, for it is mentioned by Theophrastus in the fourth century B.C.; he adds, as an instance of a similar process, that bears' grease increases in volume, "so as to fill the pot that contains it" during the period when the living bears are laying on fat.

It is necessary to lay a little stress upon the psychological background of these old beliefs, for unless we can, in some measure, think ourselves back into the attitude of mind that produces them, they are almost without meaning for us and no more than quaint mediæval bric-à-brac from which only the idlest curiosity will trouble to brush away the dust.

LAYERING TREES AND SHRUBS

AS a method of propagation, layering is becoming increasingly popular among cultivators of trees and shrubs. With an order to a nurseryman for rare trees and shrubs the stipulation is not uncommonly made that the plants must be, or should be if possible, on their own roots. This request is in many cases best met by layering. Magnolias, rhododendrons, hamamelis, cornus, hippophæ and lilacs are half a dozen instances of shrubs which generally speaking are best increased by layering. Admitted that rhododendrons are very largely propagated by grafting, a proceeding which is perhaps best described as a necessary evil.

When the branches of the tree or shrub are near the ground layering is a fairly simple matter. The usual procedure is to make a sloping cut near a node, reaching about half-way through the stem, partially to arrest the flow of sap. This is fastened in the ground with a hooked stick or kept in position with a large flat piece of stone; in either case it is covered with sufficient soil to keep the stem moist, this being very important to assist rooting. A twist of the stem to split the bark, or scraping away a little of the bark from the underside of the stem, will, in some cases, induce rooting. In a wood, branches on the ground first blow hither and thither damaging the bark until some finally get fixed with decaying vegetable matter and eventually root. To hold the layers, if of any length, firmly in position, give each one a stake. This is not only a support but when tying it usually means bending the stem, which is an additional advantage to check the flow of sap.

METHODS TO BE EMPLOYED IN LAYERING MAGNOLIAS.

The actual length of the layers will vary, an average being from 6ins. to 2ft. according to the shrub. There is something to be said in favour of large layers to obtain good plants quickly, but experience often shows that a small stem roots quicker than a fair sized woody branch and in the long run there is not much gain.

The time occupied in the development of roots varies considerably with different kinds of shrubs, from one year with those which readily develop a new root system to two years in the case of magnolias and rhododendrons. Having ascertained that the layers are well rooted sever the branches forming the connecting link with the parent plant some weeks, or even two or three months, before lifting the layers.

When the branches are not low enough on the stems to bend down and reach the ground, some device, such as that illustrated with the magnolia, must be adopted. The most important item with this arrangement is to keep the soil moist. We find it convenient to interest the garden boy and make it one of his definite duties to examine the layers every afternoon before leaving work and supply water if required. In private gardens, where only a few plants are required of new and rare shrubs, this is a very useful and fairly certain means of propagation.

The season of layering is largely a matter of convenience. Spring is often favoured because the wood is then well matured, allowing it to be cut and bent with less chance of breaking. We put down a good number of layers in late summer when growth is complete.

TULIPS AND THEIR CULTIVATION

BY C. W. NEEDHAM.

OLD Worlidge commends tulips "for their easie propagation and management and durableness in all seasons, hot and cold." The old gentleman continues:

> In the worst mold this Flower better thrives,
> And barren earth miraculously gives
> More beauty to it, than a fertile ground,
> And when least strong it is most comely found.

The cultivation of the tulip is a very simple matter in the cramped area of the suburban plot or in the spacious garden of the demesne. Tulips will grow in almost any soil if that soil is weak and the climate or atmosphere of the surroundings not of the best. If the environment is unfavourable to plant life, the tulip will bloom bravely and brighten the outlook, even though the best results will not be obtained.

Those who would grow what flowers they can under the difficult conditions of limited garden space and impure air with its attendant evil, a more or less diminished light, will find a friend in the tulip; there is none more cheerful and long-suffering and none that responds more fully to sensible, loving and watchful treatment. In quite recent times city gardens have yielded tulip blooms of good quality fit for the exhibition table, though there is never a plant that pretends to be fonder of a town life than a country life.

"THEY FLUSH THE PARTERRE WITH ONE OF THE GAYEST DRESSES THAT BLOOMING NATURE WEARS."

To obtain satisfactory results to have the tulip bloom at its best, a little forethought is needful, and regard must be had to the opportunities offered, the selection of the site for the bed, and the preparation of the soil must be considered as well as the choosing of the varieties one desires to grow with the catalogue at hand to con. Tulips may grow almost anywhere, but they may be cultivated and propagated in selected spots and in suitable soils and situations, the aim being the growth of good bloom and the production of a bulb for the next season, which is the result of healthy plant action.

The growth of ordinary early varieties bedded out in some scheme of colour or decoration is a simple matter, depending on the selection of suitable bulbs of Duc Van Thol and early and mid-season blooming varieties of more or less dwarf growth. In dealing with May-flowering varieties with their long and graceful stems a little more care and consideration is needed. A site should be selected for the bed that is screened from the prevailing winds, especially from the cutting north and east winds, so that when the tulips "begin to raise themselves on their fine wands or stately stalks," as Hervey meditates, they may bloom in tranquillity and not be beaten down. The old Dutch, the cottage, the Darwin and the English tulips offer a wide range for selection. It is with these varieties that bloom in the latter half of the month of May that we are dealing with more particularly.

The English tulips, the florists' flowers, are the highly cultured classic branch of the family of tulips, and they come with the apple blossom. Hervey says of them "they flush the Parterre with one of the gayest dresses that blooming nature wears. Did ever beau or belle make so gaudy an appearance? Here one may behold the innocent wantonness of beauty; here she indulges in a thousand freaks and sports herself in the most charming diversity of colour."

In these days perhaps we value more highly the breeders in their bright unfigured morning dress.

Though the tulip is not fastidious as to soil—for it will grow in any good garden ground—it does certainly love a soil that is stiff and deep. A well worked, heavy soil, coarse in grain, roughly granular, enabling water and rain to pass freely through, is good. It should not be peaty or impregnated with metallic oxides. Soil that has grown beans or peas, or soil that has been previously manured for a vegetable crop, will do admirably. A covering of turfy, chopped up sods from a heavy old pasture is a capital stimulant if help is needed. If the same bed is used once or twice it suffices if the covering material is new. Should the same bed be used over a period of years, it is well to sprinkle the soil after taking up the bulbs by scattering on salt until it resembles a light fall of snow. Again, a dressing of lime is most excellent; tulip bulbs love lime. Good quicklime should be stored in a box or dry place and be allowed to fall into a powder, oxidised by air. This fallen lime, thus powdered like flour, will be readily assimilated by the soil. On the other hand, should the quicklime be heaped on the ground preparatory to forking in, the lime is apt to granulate and not be so readily absorbed.

Another method of sweetening the soil in cases where the same bed does duty several years is to grow another crop after bulbs are lifted, say of turnips or mustard, which should be dug in a month before planting. Frequent changes of soil are desirable and the old soil should be taken out of the bed to the depth of two grafts, and fresh suitable soil replaced before planting time comes round. A change of air, as well as a change of situation, is most advantageous to the stock of tulip bulbs, especially is this the case with seedlings and delicate or tender varieties. Ground may easily become tulip-sick, and in cultivating bulbs *qua* bulbs a change of situation is most beneficial.

Bulbs grown in a lean dry soil are apt to split up into small bulbs and bulblets; these should be grown in a "fat" bed to restore their size and vitality and promote to the fullest extent the natural increase of the stock. Seeking for a "fat" bed go to the kitchen garden and take soil from a bed that was well manured and has grown a vegetable crop.

Biodiversity Heritage

Never use nitrogenous manure in a tulip bed. If manure seems to be indicated while the bed is being prepared, sprinkle a little bone meal or kainit or dust lightly—if available—with the very best guano. Artificial aid should be resorted to sparingly, and only then in cases where the bed has been neglected, even though it has been fallow for a time. It is far better to change the soil to the depth of 2ft.

Experience shows that in order to produce the finest and most refined bloom, and at the same time grow healthy bulbs for the next season, the foregoing rules should be observed, and, above all other rules, remember the covering material must be new to the tulip bed and of the best quality procurable, and the soil should be kept open by slight hoeing, as aeration of the soil is vital.

TULIPS GROWN UNDER PROPER CULTURAL CONDITIONS.

Do not try to push the plant and make fine blooms. The "spanking" flowers may come all right and the colour may be brilliant, the marking, if marking there be, may be fine, but all at the expense of the new bulb. The desiderata should be fine flowers and healthy bulbs of flowering size.

The tulip appreciates watchful care during its season of life, safe out of harm's way under the soil of its well drained bed or quietly doing its work within itself in the summer in its dry, airy shelter protected from insect and animal ravages. Perhaps all this seems "trouble," but trouble is not an evil to a true florist; trouble adds value to success, which is all the higher for not being easily won.

We allude to the "covering stuff" because tulip bulbs are better planted on the soil and then covered rather than dibbled in, as is customary when decorative groups are grown bedded with arabis, forget-me-nots or other dwarf plants; here the general effect is studied and beautiful pictures made by the true amateur who studies colour and decoration; as for the bulbs, well, the nurseryman provides the bulbs.

After the bed has been made fairly solid it should be finely raked on the surface ready to receive the bulbs, which should be placed thereon 4ins. or 6ins. apart, bedded in with fine soil slipping off the spade to the depth of 1in. or 2ins. over the bulbs; the remainder of the covering material may then be broadcasted on and the whole clapped down with the spade and made firm. It is preferable to arrange that the surface of the bed when completed shall be slightly raised, and, if the bed is on a lawn, it may be rounded, so that the soil is 1in. or more higher in the centre of the bed than at the sides.

If tulip beds proper are made, each bed should be 4ft. or 4ft. 4ins. wide, of any desired length, with a centre walk or path, the beds on each side being 9ins. or 1ft. higher than the walk. The bulbs should be planted in rows 6ins. apart and in spaces or holes across the bed 6ins. apart, also seven bulbs in a row. Thus in a 4ft. bed, number one bulb in the first row is nearest to hand and number four is always in the centre of the bed and number seven in the top hole across the bed. A line may be run down the middle of the bed as a guide when planting. If the bed is boarded or tiled at the sides, it need not be exactly 4ft. wide. A few inches wider bed is useful to allow for the falling away of the soil when the edges are not protected. When the beds are made in this old-fashioned way, they may be arranged and planted in the study—by intention—and a book kept and the quality of each bloom noted therein.

In the old days the amateur had boxes, ten rows of seven holes each row across the box. These little compartments each held a bulb, and the whole box contained seventy holes and seventy bulbs therein—rows 1 to 10 in Box No. 1, rows 11 to 20 in Box No. 2, and so on. Each box was a drawer in the tulip cabinet. The enthusiast, with the aid of this book, could at any time find the bulb in his cabinet, or the spot where it was growing in the bed, and tell you how it bloomed this year, last year and years previously, and descant on its qualities and dream of its potentialities and possibilities. What if fond hopes were often dashed to the ground, one had always the pleasure of expectation and anticipation; sometimes came the joy of realisation! One has often heard the remark, "The tulip book looks better than the bed."

If tulip boxes or trays are not handy, having gone out of fashion, a few bulbs of each variety may be grown, planting across the bed for the first row and on into the second row until the stock of that variety is exhausted, then a peg or stick is inserted with the number or letter of the lot as marked on the bag, in nursery fashion, where, from motives of economy, bulbs of one variety are grown together for

FOR BEDDING PURPOSES MAY-FLOWERING TULIPS ARE IDEAL.

Digitized by Google

commercial purposes, and not for display nor to indulge one's fancy.

When the tulips are past flowering the seed-pods should be removed—except in cases where seedlings are being raised—when the stalk has withered and the plant died down, then comes the time of lifting, and the 6ins. of space between rows is appreciated. Lifting-time usually comes about the end of June.

The outer skins of the bulbs should soon be removed and the bulbs stored in their respective bags or boxes in a dry, airy place. It is well to close the bags, leaving an air space inside, and generally to protect against attacks from "green fly" and other aphides which suck the ripe juices of the bulbs and diminish their vitality, as well as protect from mice. In cases where beds are needed before the stage of the dying stalks comes the plants are usually carefully lifted and heeled in elsewhere until they have died off. If bulbs from these plants are required, remove within a month and store.

In the old days, when tulip cultivation was so common and seedlings so plentiful, before the system of bedding out of tender plants during the summer months so rapidly increased and the taste for the tulip and other florists' flowers declined, much study was bestowed on the arrangement and diversity of flowers in the tulip beds. A great point was to have no two flowers that were alike next to each other, and to scheme to have the blooms of the same height in the same row, the taller varieties in the centre line and the shorter-growing ones nearer to the sides of the bed. A tent or an awning could be erected over the beds at blooming-time for the protection of the bloom, to abate the rigour of the direct sunlight and to provide fully for the enjoyment of the bloom, when one's friends would be invited and the merits of the flowers discussed.

In these days, when marking is not as yet so much desired, less elaborate arrangements are made, though often the bloom is protected in some manner. One has often been asked why this is the orthodox way; why seven bulbs in a row and 6ins. apart? An experience of thirty-five years growing florists' tulips, adding to and eliminating from the beds, seedling raising and quality appraising and taste cultivating—for after appreciation taste grows by cultivation like one's bulbs—makes one recognise the skill and knowledge of our grandfathers. The quieter joys of the garden were perhaps in those days more delighted in, yet in these later times when "incessant struggle renders life one scene of toil, of suffering and of fate" rest and peace is found in the cultivation of the tulip in the garden, even though in the contemplation of the tulip bed there may be some disappointment mingled with the joy and satisfaction it gives. New plans may be formed, new schemes of colour devised and hopes of one's seedlings indulged in. Thus we get relaxation and recreation.

A SUCCESSFUL AUTUMN SHOW OF ROSES

GREATLY daring, the National Rose Society broke away from the traditions it had established, and held its autumn show in tents and, more, made it a two-day function. We have become so accustomed to the Autumn Rose Show as to be in danger of forgetting that this feature has not been over-long established. Misanthropes, at its inauguration, true to their nature, predicted utter failure; but the innovation was immediately successful, so much so that the Royal Horticultural Society's Hall has proved inadequate for its requirements. There is no suitable hall available, so, no doubt after serious deliberations, the executive of the National Rose Society decided on the same venue as for the Summer Show.

Fortune favours the bold, and we are unfeignedly glad to record the great success of the Show which was held at Regent's Park on September 11th and 12th last. The weather, which has spoilt so many outdoor events this year, was kind. The morning of mornings dawned fair and dry, with some welcome bursts of sunshine during the afternoon; the conditions held good for the whole of the two days. There was a gratifying attendance, and the large tents contained an abundance of lovely roses. As usual, the arrangements worked smoothly, and Mr. Courtney Page and his band of assistants are to be congratulated on them.

Another "new departure" with the Autumn Show was in connection with the large "representative groups of cut roses." This year each of the very many exhibitors was allotted a separate table, and this method not only made the Show more attractive, but prevented any possible congestion in the large tent. The first prize in the larger class was won by Messrs. S. McGredy and Son with a charming arrangement of baskets and pillars of splendid roses. Their principal varieties were The Queen Alexandra Rose, Miss Willmott, Una Wallace, Mrs. C. Lamplough, Golden Emblem, Mrs. Henry Morse and Ethel Malcolm. The blooms in the second prize group of Mr. E. J. Hicks were even better on the second day of the Show.

There were no fewer than twelve tables in the class which provided tables 8ft. by 6ft., and these also must have caused the judges considerable anxiety. Messrs. William Lowe and Son were placed first with a striking arrangement of pillars of roses arching to a centre of Christine. Mr. C. Gregory, who was second, had masses of delightful blooms.

The various classes for smaller collections did not induce so great competition, but the quality of the blooms was very high. Mr. George Prince, in his twenty-four varieties of decorative roses, included lovely vases of Los Angeles, The Queen Alexandra Rose, Betty Uprichard, and beautiful blooms of Mrs. Henry Stevens.

Mr. John Mattock was equally successful with his collection of thirty-six varieties of miscellaneous roses. His first prize effort included Isobel, George Dickson, The Queen Alexandra Rose, Padre and Golden Emblem of exceptional merit. Mr. E. J. Hicks had the best eighteen varieties, and the outstanding vases were of Hawlmark Crimson, Red Star, Golden Emblem, Innocence and Mme. A. Chatenay. Mr. George Prince, who was a good second, included Allan Chandler, Golden Ophelia and Los Angeles.

Although not so numerous, the baskets of roses were as beautiful as at the Summer Show. The best three of exhibition varieties were Frau Karl Druschki, Hugh Dickson and George Dickson, shown by Mr. George Prince. Golden Emblem, Mrs. Henry Morse, Lieutenant Chauré, Isobel and The Queen Alexandra Rose, shown by Mr. W. Bentley, won the first prize for five baskets of decorative roses. Excellent baskets of Covent Garden, Golden Emblem and Los Angeles won first place for Messrs. D. Prior and Son, who, with lovely baskets of Else Poulsen, Kirsten Poulsen and Ideal, also showed the best dwarf polyantha roses.

While there were only two collections of twenty-four exhibition roses, they were very meritorious. Messrs. D. Prior and Son won the first prize with such sorts as Mrs. Murray Allison, an enormous pink hybrid tea of perfect shape, which won the silver-gilt medal as being the best bloom in the nurserymen's classes, Sovereign, Mrs. C. Lamplough, Betty Hulton, George Dickson and Edith Cavell. Mr. C. Gregory, the second prize-winner, included excellent specimens of Mildred Drew, Mrs. C. Lamplough and Bessie Chaplin.

Mr. George Prince had the best eighteen blooms of exhibition roses, and his was a very clean and even collection of really good blooms. The very best were Mabel Morse, Juliet, J. G. Glassford, George Dickson and Frau Karl Druschki. Mr. G. Longley was second, and he also was first with such tea roses as Lady Hillingdon, The Bride, Maman Cochet, Mrs. Foley Hobbs and Molly Sharman Crawford.

AMATEURS' ROSES.

In view of the weather of late, the quality of the blooms in the amateurs' classes was surprisingly high. There were very few weather-stained petals to be seen, the blooms were of typical size and shape, and the colouring was very good. Mildew, which is often so prevalent in the autumn, was practically non-existent so far as the foliage at the Show was concerned.

The first prize collection of twelve exhibition blooms shown by Mr. J. N. Hart, Potters Bar, included excellent specimens of such sorts as Mrs. C. Lamplough, Mildred Grant, Admiration and Gladys Harkness. Mr. F. H. Fieldgate, Colchester, who was second, showed George Dickson and Frau Karl Druschki in splendid condition. Mr. C. Dixon, Sheffield, showed twelve blooms, in not fewer than nine varieties, in admirable condition. His first prize set included George Dickson, Gorgeous, Annie Crawford and J. G. Glassford. In this excellent class Mr. W. E. Moore was second, and he had fine blooms of Hugh Dickson and George Dickson.

Mr. R. de V. Pryor, Hitchin, with a rather uneven half-dozen, won the first prize, but his blooms of Lemon Queen and George Dickson were particularly good. Mr. I. J. Cole, Treherbert, North Wales, was a successful exhibitor of exhibition roses in the smaller classes. Mr. A. N. Rogers, East Putney, had the best blooms grown within ten miles of Charing Cross; and Mr. W. E. Moore, High Wycombe, who staged such varieties as Bessie Chaplin and George Dickson of great merit, had the best six distinct blooms of those members who have no assistance whatever, and he was also easily first with nine very creditable tea roses. Mr. Fieldgate was a very good first with six tea roses. The principal varieties in these classes were W. R. Smith, White Maman Cochet, Mme. Jules Gravereaux and Mme. Vermorel.

The decorative roses provided some feasts of colour and fragrance. The baskets were particularly good, and first prizes were won by Mr. J. N. Hart, Mr. R. de V. Pryor and Mr. T. E. Tattershall, Orpington.

Digitized by Google

with excellent baskets. Mr. H. R. Darlington has many times won the first prizes in the chief class for vases of decorative roses, but he has rarely done so with better blooms than on the present occasion. He included Moonlight, Padre, Golden Emblem and Mme. Edouard Herriot. Mr. J. N. Hart was a good second in this popular class. In the pure amateurs' class, which also drew many exhibits, Mr. J. E. Rayer, Worcester, won first place, and he had lovely vases of Vanity, Moonlight and Irish Elegance. Mrs. L. A. Tilley, Northwood, was second. The best bloom in this section was a splendid example of Edward Mawley, shown by Mrs. C. E. Whitcombe.

TABLE DECORATIONS.

As usual, the dinner-table and vase decorations filled a large tent and there were numerous exhibits in all the classes. In the open section, Mrs. A. R. Bide, Farnham, added to her very many successes by winning the first prize. She made artistic use of Rose Madame Butterfly with a few sprays of Rosa sericea pteracantha, whose shining scarlet thorns gave just the needed touch of bright colour. Mrs. L. R. May, Waltham Cross, was second. A very attractive table of Isobel did not seem to be placed.

In the amateurs' section the first prize was awarded to Mrs. Oakley Fisher, Sudbury, who used the pink Roselandia with purple shoots very effectively. Mrs. Courtney Page, Enfield, employing Emma Wright and sprays of Rosa sericea pteracantha, was a good second. In the classes for vases and bowls, Mrs. Courtney Page won two first and one second prizes, and Miss E. Griffith, Finchley, was first with a bowl of mixed varieties.

THE CORY CUP.

At each of the N.R.S. shows of the year new seedling climbing roses have been exhibited in competition for the Cory Cup, which was awarded to the charming Phyllis Bide, shown by Messrs. S. Bide and Sons. The free-flowering climbing polyantha received a certificate of merit a year ago and the highest award of the Society's gold medal at Glasgow last month. It is almost everblooming, for it flowers freely the first year on the young growths and continues throughout the season. The colour is pale golden yellow flushed with bright carmine towards the edges. The flowers are almost double and are produced in long loose sprays.

Also in competition for the Cory Cup, Messrs. S. McGredy and Son showed Lady Margaret, a sweetly scented hybrid tea variety which bears double flowers on good stems. The variable colouring is generally yellow heavily shaded with purple.

THE LARGE SHAPELY BLOOMS OF LORD LAMBOURNE.

A DWARF FREE FLOWERING H.T. VARIETY, DOROTHY KING.

NEW ROSES.

ARTHUR COOK.—This variety was presumably shown for the higher award of a gold medal, as it previously has received recognition. It is a very desirable hybrid tea rose, but falls just short of gold medal standard. The good-sized, globular flowers are made up of large, substantial petals of bright-edged, dark crimson colour shaded with maroon. It is pleasantly fragrant. Shown by Messrs. S. McGredy and Son.

CLOVELLY.—A long-stemmed pink hybrid tea rose of somewhat pointed shape and La France colouring which deepens with age. It had already received a certificate of merit. Shown by Mr. Elisha J. Hicks.

CORNELIA.—A hybrid musk of, at the Show, somewhat unpleasant odour. The abundant flattish sprays of nearly double flowers about 3ins. across are attractive. They are of pale pink shades, usually brighter in the congested centre. Shown by the Rev. J. H. Pemberton.

DOROTHY KING.—A dwarf and evidently free-flowering hybrid tea variety which bears two or more rows of substantial petals, giving a solidly single-flowered appearance. The mature flowers are cup-shaped, and the scarlet-crimson colour, which is touched with maroon, is lightened by bold golden anthers. It should be a valuable garden rose where brilliant colouring is required. Certificate of merit. Shown by Mr. Ernest J. King.

EVA EAKINS.—This is a small but exceedingly brilliant Pernetiana hybrid. The fully double flowers are of perfect shape and velvety scarlet colour, with a touch of golden yellow at the base of each petal. Certificate of merit. Shown by Messrs. S. McGredy and Son.

JOAN HOWARTH.—A vigorous, fully double hybrid tea variety. The well made flowers were a trifle small, but evidently freely produced, and we suspect that in the height of the season it was a very attractive rose. It is exceedingly fragrant and somewhat suggestive of Pharisaer. The soft pink colour is shaded with apricot in the heart of the blooms. Shown by Messrs. Bees, Limited.

JUNE BOND.—An "Extra Perpetual," bearing shapely flowers on long, clean stems. The golden ground colour is heavily suffused with shell pink. It is pleasantly fragrant. Shown by Messrs. S. McGredy and Son.

LADY F. STRONGE.—This hybrid tea rose was well deserving of the award it received. It is of dwarf, free-flowering habit. The shapely flowers are of mid-pink col

Digitized by Google

flushed with rich peach. Certificate of merit. Shown by Messrs. S. McGredy and Son.

LORD LAMBOURNE.—If this large shapely hybrid tea rose possessed more substantial petals it would be a glorious variety. But the petals are rather too thin, and it is too delicate a rose for everyday use. The rich yellow petals are stippled with crimson lake towards the margins. Certificate of merit. Shown by Messrs. S. McGredy and Son.

MABEL LYNAS.—This, the best of the new seedling roses, is quite a large Pernetiana and is delightfully endowed with real rose scent—a most unusual thing in Pernetiana hybrids. The fully double, shapely blooms are of rich crimson colour with just a touch of velvety maroon. Gold medal. Shown by Messrs. S. McGredy and Son.

MRS. C. W. EDWARDS.—A free-flowering hybrid tea rose of bushy habit. The smallish flowers are of pleasing deep rose pink colour. Shown by Messrs. S. McGredy and Son.

MRS. J. HEATH.—A sweetly scented hybrid tea rose, fully double and of peach and yellow colouring, with a golden heart. Shown by Messrs. S. McGredy and Son.

MRS. TALBOT O'FARRELL.—This hybrid Pernetiana would make a very showy garden rose. It is shapely in the bud state, but becomes loose when fully open. It is of old gold colour heavily stippled with rose on the upper surface. The blooms are delicately fragrant. Certificate of merit. Shown by Messrs. S. McGredy and Son.

MRS. S. W. BURGESS.—In its rich purplish foliage and flower stems this was the most uncommon new rose in the Show. It appeared to be somewhat prone to mildew, but it has been exceptionally wet of late and the season is far spent. The sweetly scented pale orange flowers are occasionally lighter in colour at the edges, though the colour does not seem to fade. Shown by Mr. S. W. Burgess.

NORMAN LAMBERT.—A smallish hybrid Pernetiana rose of moderate fragrance. It is of good shape and very uncommon golden terra cotta colouring. Gold medal. Shown by Messrs. S. McGredy and Son.

SIR DAVID DAVIS.—This should be a very good bedding rose. It has a bushy, free-flowering habit and produces medium-sized, fully double, dark crimson flowers. Shown by Messrs. S. McGredy and Son.

SOUVENIR ROSE BERKELEY.—A hybrid tea variety of medium size, good shape and vivid pink colour which would be valuable for garden purposes. Certificate of merit. Shown by Messrs. S. McGredy and Son.

VEGETABLES FOR AUTUMN ATTENTION

ONCE the summer is over, and possibly the local horticultural show has passed, there arrives a period when the small grower seems rather inclined to rest on his laurels and content himself with garnering such crops as he has raised for winter store and supply. Of course, there has been that strenuous spring period, when, perhaps, he has had to work against time, and later have followed the summer months, with their increasing cares of the growing crops, that make one sympathise with that "worked out" feeling. But is the tendency to ease off one that should be encouraged? The only answer is that it should not, for during the autumn months there is much that can be done. Not only can good vegetable supplies be arranged, for utilisation in the coming few months, but a great deal can also be accomplished to ensure a sufficiency of such commodities for the period when otherwise there will be a shortage of home-grown supplies at a time when scarcity reigns and prices run high.

It should be the aim of all good growers to bridge this gap, a gap, incidentally, that oftentimes teases the professional grower (as witness the shortage period), and it should be the aim of all those who make a success with their garden, or allotment, to keep the supplies running, if possible, the year round. Now is the season for full use of the cold frames, the lack of which in small garden, allotment and small holding one can only bemoan, for they are more than useful during the winter months.

September is, of course, the busiest period, the more so as lifting and storing of various items will be in progress, while other crops will be ready to clear off the ground, having finished their period of usefulness. However, during the month the main batch of the ever welcome spring cabbage should be planted out, and a useful site for this is the ground from which onions have been lifted. With this cabbage, only allow 18ins. between the rows and a foot from plant to plant; then, very early in the spring, the alternate plants can be taken out, leaving the permanent ones 2ft. apart, and those lifted can well be employed to fill up gaps that may have occurred owing to adverse winter conditions. Also of the cabbage tribe, and forming a welcome change in green diet, are the coleworts, and for a late batch some of these should be planted this month. Endive of earlier sowing should be pricked out into cold frames, allowing about 6ins. between plants, and these will be found most useful during the winter months. The same process may also be employed for lettuce.

September sowings are of a good number. During the month, cauliflowers, such as Walcheren and Magnum Bonum, should be sown in frames, about the second week being the best, and at the end of the month the resulting small plants should be pricked out into cold frames, about 4ins. apart. In these frames they can be wintered, protecting when adverse weather is about, and freely airing on all suitable occasions; they will then be ready for planting out in March and April, in a sheltered part of the garden, where they can be protected if necessary, and will then give early yield. Parsley, too, can be sown this month and similarly pricked out in cold frames for winter use. Radishes, too, sown in frames at this time, return autumn supply. Two or three sowings at ten days' interval, can also be made in September, and even if conditions are against them forming good bulbs, they will hold up well through the winter, giving a supply of these delicious "tops" in early spring. Make a final sowing of spinach, too, in open position, for standing the winter; two later sowings may be made in October, provided a warm south border is selected for the work. If potatoes have been grown in frames, they will now be cleared, and in their place a sowing of stump-rooted carrots can be made, thinning out during the next month, and these will come into use during the winter months. Thus it will be seen that much can be done during the month of September.

Now let us consider October—not such a busy month, be it confessed, but still having something for us to do. The endive, lettuce and parsley, for instance, sown last month, should be pricked out as suggested in cold frames, as also the cauliflowers, during the intervals which occur between such operations as earthing-up late celery, harvesting—or rather, storing—the onion supplies and hoeing through other growing crops. The latter will take up considerable attention in order to keep them free from decaying matter and other rubbish, such as weeds. It may here be noted that the blanching of the endive, when necessary, can be accomplished by covering over such as is required by means of a mat or similar device; the lettuce will not require this treatment. A late batch of cabbage may also be planted, in order to get a late yield of this, as such may be of great advantage in spring when vegetables of other forms are unobtainable. When planting this lot, do it carefully, and be sure to draw the soil up round the stems for winter protection, the stem being a point that is particularly vulnerable to the attack of frost. This device should be adopted for all the batches. Too much emphasis cannot be laid upon the importance of this crop, and the raising of cauliflower as suggested, for time and again the writer has found them invaluable when conditions have been such, during the winter months, that shortage of other vegetables has been inevitable later.

During October all plants of endive and lettuce standing in the open should be lifted and planted in cold frames thickly together. They will not hurt if actually touching, for often space is limited, and as many as possible require to be packed in. To continue the supplies from Christmas to Easter, the September seedlings should be planted into the frames at intervals so as to arrange for a succession of yield.

November calls for less attention, the principal sowing being, where the facilities of heated houses or pits are available, French beans, sowing in 8in. pots, five seeds to a pot, and raising in a temperature of about 65° Fahr. Mustard and cress may be sown at frequent intervals, more frequently for mustard, for it is ready more quickly than the cress, and during the winter this ever welcome small salad requires a certain amount of heat, say a temperature of about 55 Fahr., and should be sown according to the supply necessary. Much useful work can thus be accomplished in planting, sowing and lifting vegetables during the autumn months.

EDWIN BECKETT.

CORRESPONDENCE

ROSES AS ISOLATED BUSHES.

SIR,—The accompanying illustration of the rambler rose Ariel will give an idea of what may be accomplished by planting this and other varieties of the multiflora ramblers as isolated specimens. The prevailing idea is that these roses must of necessity be planted against some support. Here we have a specimen growing naturally, the drooping nature of the growths aiding in its floriferousness and, as may be seen, the specimen is admirably set off by the fine background of evergreen trees. Ariel is a delightful single flower, probably of the same parentage as Tea Rambler and introduced by the well known firm of Paul and Son. Mr. George Paul, who did so much to encourage this style of planting, would have loved to have seen this specimen, as possibly he may have done, for its owner and he were great friends. Unfortunately, Ariel flowers but once in the year, and that is in early June, but there are to-day many fine roses that are perpetual bloomers that may be similarly grown,

A MAGNIFICENT BUSH OF ROSE ARIEL IN AN ADMIRABLE POSITION.

such as Moonlight, Pax, Danöe, Lady Waterlow, Zéphirine Drouhin, Grüss an Teplitz, etc., and even such kinds as Irish Elegance will with no pruning soon develop into huge bushes.—(Rev.) F. PAGE-ROBERTS.

THE PURPOSE OF WISLEY.

SIR,—I should like to reply to Mr. P. A. Hendley. The pedantic tone of his letter (page 637) is his affair, but the inaccurate statements and insulting reference to the horticultural trade is mine. Fortunately, there must be few readers of THE GARDEN who will accept his statements, which seem to me to be wild and sweeping, and so are robbed of logic. I challenge Mr. Hendley to prove his statement that a rose distributed in 1890 was again renamed in 1902 and yet again in 1911. I shall want him to stick to roses and not talk about primulas to prove it. I would also ask Mr. Hendley to substantiate his statement that every catalogue is full—too sadly full—of inaccuracies. If he can do neither he should apologise. Can he tell us where he or any amateur can obtain such good return for time and money spent on a hobby as from the horticultural trade against which he so grossly bears false witness?—LAURENCE J. COOK.

MAGENTA.

SIR,—"M. H. W." (page 590) may like to hear about some grey and magenta borders which I made some years ago. There is, in this garden, an old walk more than 130yds. long, with herbaceous borders on either side. I never allowed a gardener to touch them, doing every scrap of work myself until illness put a stop to my labours. Now, after five years of gardeners' attentions, there is literally not a patch of my dear magenta left.

I find surroundings affect colours so strongly that I shall not put magenta in one place where it used to be—it looked flat and ugly. My best and favourite patch was at the far end of the walk, where the tall plants stood up in full sun against a background of deep shadow under some trees, etc.

The patch was nearly 30yds. long, and on the left-hand side I gradually made it almost all magenta with drifts of grey, and grey in front. By degrees, mauve vanished from that side, and a little bright blue and very pale yellow took its place. On the other side I placed much more grey, less magenta, and more of the paler shades of blue pinks and warm mauves. On the left-hand side I planted a "drift" which attracted much attention. Two or three bushes of tansy, with three groups of seakale plants. One group trailed to the fore and met a large patch of pinks which, in its turn, trailed off and formed a border for some distance. Behind the tansy was an old rose, which grew, like Topsy. I fancy it was the stock of some defunct modern failure. The Japanese "crimson" was good there also, but it was planted too far back and invited too much attention from my deadly enemy, the hoe, and so died an unnatural death. I did not replace it, as its foliage rather worried in that special spot.

Round about the tansy and seakale I had the darkest magenta (not purple) geraniums and erodiums, and behind, catching up the blue colouring in the seakale, two or three light blue and sky blue delphiniums. I found it difficult to get just the right colouring, but at last unearthed one with a dash of green in the blue, and two pure sky blue ones. The whole group gave me intense joy, and when I next start planting shall increase it in size.

Here is a list of plants from my old note book:

For back row—Hollyhocks, dahlias, roses, everlasting pea (a stiff sort, perhaps Drummondi), sweet peas (there is a lovely one now, I think it is either Royalty or Royal Purple phlox, and the old "red" Michaelmas daisy. The phlox is an old cottage one, rank in colour and growth, but charming when mixed up with the Michaelmas daisy, which flowers rather later as a rule. Clematis and epilobium.

For the middle—Lythrum Rose Queen, lupin, thalictrum, asclepias, geraniums, phlox, gladioli, peonies, English and Spanish irises, bearded iris, allium (must not seed), chrysanthemums, pentstemons, erodiums, honesty, veronicas (two sorts).

Front rows—Pinks, carnations, centaurea, tulips, anemones, hyacinths, violas, thyme, aubrietia, tradescantia, erodiums, and gaps filled with petunias, ivy-leaf geraniums, clarkia, candytuft, etc. Some sisyrinchium with pale yellow flowers seeds itself along the front, and I say a polite word of thanks to it even now.

One of the most beautiful magenta flowers I have ever seen was an English iris which came to me under the name of La Nuit—from Van Tubergen's. I left it in a garden and have never succeeded in getting it again. It was a rich glistening colour with a thick "frost" upon it.

My next attempt will have more bearded irises in it, even if the colours are not quite right—the foliage is such a great help; and I shall certainly put more blue, or rather, carry it on by having commelina and salvias, etc.; but very little is required, as the general effect is so easily destroyed. I amused myself with several unusual patches along my border. A small chocolate one was most interesting, with huge plants of Veratrum nigrum coming well to the front; wine-coloured pansies and a large mass of scarlet pimpernel to lighten the effect made a most unusual bit of colouring. It required very careful attention and thought as to background and foliage, and I removed it from oranges and yellows. I found a large drift of golden feather very useful, also the tall ageratum in a mass; both of these plants were jeered at close to, when it was a case of "If you are discovered you are lost"; but until discovered they were always much admired—H. P. M., *Notts*.

ARRANGEMENT OF CUT FLOWERS.

SIR,—In the article on the arrangement of cut flowers, on page 594, I see it is stated that it is inartistic to use a mixture of flowers. On the contrary, flower mixtures are now very popular with artists. The following flowers arranged in a rather large pottery bowl made quite a picture: Marigolds, polyanthus in shades of red, yellow and blue, mauve single stock, pansies, woodruff and Virginian stock. Later on in the summer a mixed vase containing love-in-a-mist, annual larkspurs, snapdragons and sweet williams was much admired. Just at present tall vases filled with golden rod, rudbeckias, montbretia and the brown seeding spikes of the common stock are far more effective than the same flowers arranged separately.—A. BLOIS, *St. Briac*.

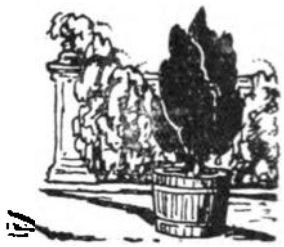
SIMPLE GARDENING



LOOKING ROUND THE GARDEN.

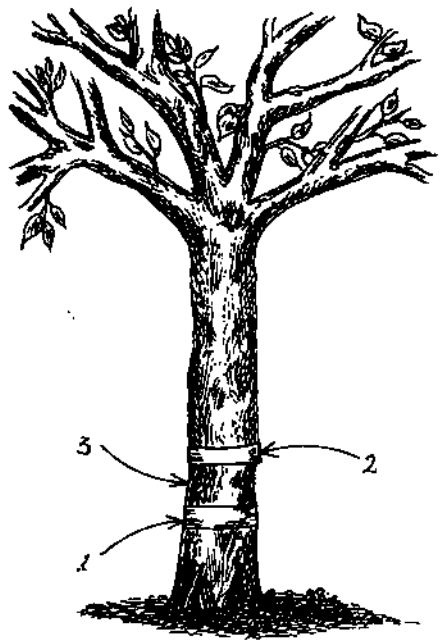
WE all do so, some out of curiosity, some to find fault, some thoroughly to enjoy the beautiful features not dreaming of any criticism, others to see how improvements may be made. It is with the latter object that I invite my readers to have a look round their gardens now. One should take note of both failures and successes, and not rely too much on memory as each season brings its special duties. First, perhaps, the flower borders should be inspected, especially the herbaceous ones, also the rockery. New plants to be purchased for these should be made note of and also any soil for filling-up work and additions. Plants in the herbaceous border to be lifted should be labelled for that purpose, or improved positions for certain others marked in readiness. Then there is the vegetable garden to be inspected. Liming may be beneficial, note this; crops not succeeding in any particular quarter may do better in another; notes again will help. Very successful crops should also be observed and their recent treatment borne in mind so that such successes may be more numerous next year. Fruit always attracts attention and, perhaps, causes the most anxiety to the gardener. Apples and pears require several years in which to grow and become fruitful, so if there are any specimens decidedly unremunerative grub out all such and replace them with really healthy young stock now, thus saving a whole year's time. Decide now on any necessary root-pruning and take note of boundary fences.

LIFTING OLD SUMMER BEDDING PLANTS.

There are hundreds of amateur cultivators in every county who are unable to propagate cuttings in the early autumn but must rely upon the old plants as stock for next year. Of course, the cuttings are more difficult to keep through the winter, but old plants, too, require very careful treatment. We may consider zonal pelargoniums first. These old specimens possess many long roots and also long, straggly shoots. When lifted with ordinary care some of the longest roots and branches, respectively, should be cut back, thus having a balance between shoot and root. In the meantime a few bushels of soil should be passed through a half-inch mesh sieve and stored in a cool, dry place to become almost powdery. When the old plants are potted up it will only be necessary to crock the pots, press into the smallest possible the roots of a plant and work in among them the fine soil prepared. In larger pots several plants may be wintered. The fine soil is easily settled firmly round the roots by applying clear water. Old heliotrope, fuchsia and similar plants may be treated in a similar way. Be careful not to overwater after the first application. These plants are best retained in well ventilated houses, while old plants of gazania, alyssum, lobelia and ageratum should be first treated in cool frames. Every week all fading leaves should be removed—not forcibly pulled off.

GREASE-BANDING FRUIT TREES.

In October this work is done wholesale, but I think it is a wiser plan to do it in September, as the female wingless



moth is sometimes early at work climbing the trunks and any supports to gain access to the branches. This year, perhaps, early climbing may not occur, as nearly everything is a fortnight late. Bands for the purpose may be bought ready to apply from firms advertising in THE GARDEN. But if home-made bands are used, those formed of brown paper or rags will do. I prefer two bands on each stem as shown in the sketch. Nos. 1 and 2, being 3ins. wide, and a space of 9ins. (No. 3) left between. Any lasting grease, cart-grease, for instance, will do. I like to soak the bands in oil first, then they cling closely to the bark. Renew the grease once a month.

POTTING FREESIAS, ROMAN HYACINTHS AND NARCISSI.

The work of potting and giving after-attention to bulbs is very fascinating. These bulbs may be grown with success in pure leaf-soil, especially the Roman hyacinths and narcissi, but there is no need to experiment generally, so we rely upon a compost of sweet loam two parts, leaf-soil one part and sand one part. If these ingredients are not available, use, if obtainable, the general compost from the melon, cucumber or vegetable marrow beds, omitting any of the actual hot-bed material, as feeding is best carried out after the flower-buds form. The freesia bulb is small, and on that account cultivators sometimes place too many in each pot, with the result that the flowers are smaller than they ought to be. It is very important that the pots be clean and dry, especially inside, when used. The crocks for drainage need not be numerous, but well placed. Fill up the pots with soil for the freesias and press them into the surface, covering with rather less than 1in. of soil. Three Roman hyacinths will be sufficient for a 5in. pot, while five may be grown in a 6in. one. In the case of large sorts of narcissi, such as Emperor, nine bulbs may be grown in a 7in. pot—four in the bottom and five at the top—where many blooms are required from a pot of this size. All will bloom at the same time. Water all pot bulbs and cover with sand, coconut fibre or leaf-soil with the exception of freesias. Place these in a darkened frame.

BORDER CARNATIONS IN WINTER AND SPRING.

In some soils these plants will succeed without any special care being bestowed upon them. In other soils there is always some trouble with them. Now, where difficulties arise during the winter and spring in the case of plants left in the open borders, I advise cultivators to winter the newly layered specimens in a cold frame. Prepare a bed of soil, not necessarily rich, but of good loam and a small quantity of old mortar rubble, about 7ins. in depth. Carefully detach the rooted layers from the parent plants and lift each one with as much soil adhering to the roots as possible and replant them 7ins. apart in the cold frame. The glass lights should be kept closed for ten days after planting and watering, then fully expose the plants in fine weather, both night and day when fogs and frosts are not prevalent. Watering should be carefully done. Only apply clear water just before the soil becomes really dry and early in the day. I have found that young plants, so treated, made excellent specimens by the next March, when they were planted in their flowering quarters and continued their steady progress. In the meantime the border soil can be trenched and left in a lumpy state for the weather to pulverise and sweeten. GEORGE GARNER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Mushrooms.—These are always appreciated, and now it is advisable to collect all the horse-droppings until the requisite quantity is obtained. These are turned over several times at short intervals to allow the rank heat to escape; then the bed should be made, and eventually spawned according to the directions given in a previous note. The shed or mushroom-house should be cleansed, and the walls given a dressing of lime-wash.

Weeds.—It has been a difficult matter to prevent some weeds producing seeds this summer, and where such was the case a fine crop of seedlings has appeared. At this period they make rapid growth, and unless they are removed the crops will be covered. In addition to making free use of the hoe, hand weeding must be resorted to and the weeds carried off. If the ground is kept clean, it will dry more quickly and the crops benefit thereby.

Celery.—The earthing-up of the early crops may be completed, and late rows should be dealt with when they are ready. Choose fine dry weather, and tie together the leaf stalks to prevent soil entering the hearts of the plants.

Spring Cabbage.—The plants put out a few weeks ago are making headway, and another batch can be planted. This crop may pass through the winter with greater success than the earlier and more advanced plants.

THE FLOWER GARDEN.

Transplanting.—A number of trees—such as box, hollies and other evergreens—may be transplanted at the present time where such operations are contemplated. Lift each plant with a good ball of soil, and after planting afford a liberal supply of water. Make the trees secure against rough winds, then each one will produce new roots before the winter sets in. Cuttings of laurel, box and other evergreens can be inserted at this season, selecting a partially shaded border.

Veronicas.—In this part of the country the numerous garden varieties of veronica are a great success, and many are to be seen in cottage gardens. They are easily grown, and a fine display is secured from July onwards if a young healthy stock is kept up. Cuttings form roots readily in a cold frame, and if only a few are required pots filled with sandy soil will suffice. Keep them in a cold frame for the winter, and put out in their flowering quarters in spring.

Rambler Roses.—If not already done, these plants should be pruned, cutting out all the old and exhausted wood. New supports must be supplied where needed, and the new shoots tied in so that they can receive all the sunlight possible.

Bulbs.—The planting of bulbs should be proceeded with, and they embrace tulips, snowdrops, winter aconites, erythroniums and a host of other fine flowers.

THE HARDY FRUIT GARDEN.

Wall Trees.—Most if not all the fruit has been gathered from both peaches and nectarines, and the trees should be relieved of all superfluous growth. The current season's growth should be retained, and as much as possible of the old wood cut out. Avoid overcrowding when tying in the shoots for next season. Where new trees are required, they should be procured and planted in the near future.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Beetroot.—Preparations should be made now to have the crops secured and placed under cover. Careful lifting and handling of the roots are necessary so that none gets damaged. To defoliate each root, the leaves may be screwed or twisted off with the hand. The roots should then be sized and placed underneath a bench or other suitable place in one of the sheds, in two or three heaps, according as the selection has been made. Each clamp should be covered with sand or fine soil.

Cabbage.—Whenever the ground is fairly dry, stir with the hoe the surface soil between the lines of the young plants which were set out earlier in the month. If not already done, the ground between sea-kale should be hoed and raked, so that all weeds and decayed leaves are cleared away.

Leeks.—Plants set out early in July should be sufficiently advanced now to have the soil drawn up on each side of the stems. This earthing-up will ensure more of the stem being blanched and their greater appreciation in the kitchen.

Potatoes.—The remainder of the second early varieties which have matured their haulms should not be left longer in the earth. If a large quantity have to be dug up, the tubers should be carefully collected and placed in a clamp in the reserve ground. Smaller quantities which are likely to be used in the kitchen within a few weeks should be put into hundredweight bags and the bags placed in the store-room.

THE FLOWER GARDEN.

Anchusa Italica Dropmore.—Plants which have gone out of flower may be dug up and have the roots cut into lengths of 3ins. Take care to make a slanting cut on the end portions of those which show little or no tapering, so that the right end will be kept topmost when they are placed into boxes of medium fine soil. By this method—of root-cuttings—an increase of plants can be obtained, if raising plants from seed has not been favoured.

Beds and Borders.—If a spring display is to be provided, the flower beds and borders should be cleared of their summer occupants. The soil, if in good heart, need not be manured, but simply dug over, then slightly firmed with the feet and nicely raked. The planting of narcissi, hyacinths, tulips, arabis, myosotis and wallflowers should then be taken in hand. The depth to plant may vary according to the soil and size of bulb; but from 3ins. to 6ins. deep may be taken as a good average. The bulbs and plants may be intermixed or otherwise, just as the individual taste and requirements of the place demand.

Carnations.—This year our plants have done fairly well; but last year the older plants provided a much greater number of flowers and likewise better furnished beds. Now that the flowers are faded, the spiral wires, used as stakes, should be collected, tied into conveniently sized bundles and laid away for next year. Then clear all old flower stems away from the plants.

FRUITS UNDER GLASS.

Peaches.—Where red spider has been very troublesome on the trees, it is a good plan, in addition to spraying, to go over the stems now with a mixture of soft soap and sulphur, applying it with a paint-brush or sash tool and working the mixture well into all places on the old wood likely to harbour the insects.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Darwin Tulips are very useful for decorative work, their long stems specially adapting them for use as cut flowers. They are by no means so easily managed as the early-flowering tulips, as they will not stand the same amount of forcing, and generally should be given cooler treatment. Larger pots, too, are necessary, as they have much larger foliage than the early-flowering varieties. If five bulbs are placed in an 8in. pot, much better results are likely to be obtained than if they are grown in a 6in. pot. If not already potted, this should be done without delay, as success depends very largely on the bulbs being well rooted. After potting they should be stood outdoors and be covered with ashes until they are well rooted, when they should be removed from the ashes and placed in cold frames.

Gladioli of the nanus and ramosus sections are very useful for decorative work, especially as cut flowers or for furnishing the conservatory. They should now be potted, and as they are free-rooting plants should be given fairly large pots—6in., 7in. or even 8in.—as with ample root room their foliage can be kept in good condition when they are in flower. Six or eight corms may be placed in a 7in. or 8in. pot. After potting they are best stood in cold frames. Where it is desired to grow them in quantity for a supply of cut flowers, they may be put up in boxes, or even planted out in cold frames. There are many beautiful varieties, in varying shades of pink, rose, red and scarlets, as well as G. Colvilei and its white variety, The Bride, that is so largely grown for market work. G. byzantinus, which is a very old garden plant and succeeds very well outdoors or in pots, is worthy of more general cultivation.

Ornithogalum arabicum, which has large white flowers with black centres, is very fine for the cool greenhouse. One bulb should be placed in a 48-sized pot. They are best grown singly, as, unfortunately, this fine species is somewhat uncertain in flowering. Some seasons every bulb will flower, while on other occasions only a proportion, or none of them will produce flowers. This is probably due to the bulbs not being properly ripened.

Ixias, which used to be commonly grown in gardens, are now seldom seen, which is surprising, considering how reasonable they are in price. There are many beautiful varieties, ranging in colour from white, yellow and varying shades of pink, rose, red and scarlet, while the beautiful I. viridifolia always attracts attention. They are ideal for a supply of cut flowers, and their cultural requirements are very simple, as they can be grown in cold frames until they throw up their flower spikes, when they can be removed to an unheated greenhouse.

Sparaxis, Babianas and Tritonias are all worthy of more general cultivation, especially for the small unheated greenhouse. They all succeed under the same treatment as advised for ixias.

Iris tingitana.—This beautiful iris is very useful for pot culture. Five or six bulbs may be placed in a 6in. pot, afterwards standing them in a cold frame. Early in the New Year, when they are well rooted and growing, they may be introduced to a warm greenhouse, where they will quickly produce their flowers, which are very useful for a supply of cut flowers. Water must be carefully afforded at the roots, as they quickly suffer from over-watering.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Sweet William Plants Dying (T. N., Bucks).—These plants are subject to a fungus attack in old soils, and especially in those not well drained during a wet season similar to the present. As you are unable to change the quarters of the plants, mix some old mortar rubble with the soil during the winter and scatter sufficient fresh lime on the surface just to cover the soil several weeks prior to planting. In the meantime keep the young plants in a nursery bed. Such trouble may not occur again for several years. If it does, sprinkle flowers of sulphur freely round the base of each plant.

Chrysanthemum Stems Splitting ("Dene").—Without seeing the stems it is impossible to say exactly what the cause is. But a normal plant will not split its stems. The latter must have received some injury. The chrysanthemum bug will eat the stems, which then have the appearance of having been cut with a knife. If the stem has been injured, the extra feeding that the plants are, no doubt, receiving would cause the split to extend.

About Passion Flowers and Growing Bulbs Indoors (Miss J. N. K).—You do not say what variety of passion flower is referred to. Cœrulea and its varieties are the hardiest, growing and fruiting in the southern counties without artificial protection. The others are not very reliable even in the South, and any tried should be protected—the stems, too, of Passiflora cœrulea. The bulbs of colchicum may be planted in pots or pans filled with stones and peat or fibrous loam, the vessel being placed in another containing water, so that the water can be changed without disturbing the roots. Bulbs of Narcissus Tazetta may be grown in a similar way or fixed in wire netting fastened over the bowl so that the roots barely touch the water in the bowl.

ROSE GARDEN.

Roses Not Flowering (S. M. L.).—No doubt the Oriental poppies robbed the roses of much nourishment and so weakened the growth, and it was the right thing to do to remove the poppies. But the plants must have been weakly to begin with or the soil did not suit them. Leave the bulbs in the borders; they will not be harmful to the roses, and apply a rich surface dressing of loam and manure. When new shoots grow, next May, feed with diluted manure water and have all the plants pruned before the end of March.

Fragrant Wichuraiana Roses (C. B.).—The roses of the above class have been crossed with so many parents that many of them are lacking in scent. There are, however, many scented ones, but not much grown. Some of the most sweetly scented are Gerbe Rose (large, pure pink flowers, early and late), François Juranville (fawn pink, early summer), Léontine Gervais (salmon rose, early) and Evangeline (lavender pink, white centre, single, mid-season). Others less strongly scented are Débutante (pale pink, late summer), The Gem (creamy white), Sylvia (lemon to white, summer and autumn), René André (saffron yellow, early), Paul Transon (salmon pink, early, tea-scented), Mme. Portier-Durel (pure white) and Auguste Barbier (rose shaded lilac, early). It is quite likely that rabbits would eat or gnaw the stems of violas. It would be an advantage to know what they would not gnaw at times, apparently to shorten their teeth, without any real liking for the plant.

Rose Laurette Messimy (H. W.).—As Rose Laurette Messimy appears to be just too tender for your exposed situation and you like it, we should suggest you try Mme. Eugène Resal, which is very similar and distinctly hardier.

THE GREENHOUSE.

Carnations Unsatisfactory (M. L.).—The leaves enclosed for inspection indicate clearly that the plants have been subjected to a too high temperature, with the result that they are nearly eaten up by red spider. During the summer the plants, growing under glass, should be judiciously shaded, receive abundance of air and no artificial heat. Of course, old plants are difficult to manage at this season, and the sooner they are replaced by young stock the better. Young stock should be kept away from the house till the latter has been cleared of red spider, the old plants being destroyed. The leaves of the pellionia may have been eaten by caterpillars or small shell snails. It is not possible to say what has eaten them, without seeing the leaves.

TREES AND SHRUBS.

Azaleas Attacked (Miss M. K.).—The leaves sent for examination show signs of being eaten by small shell snails or slugs, as well as by caterpillars. If all the foliage is similar to that sent, much damage has been done. Procure some quassia chips, make a weak solution and syringe the bushes two or three times, directing the fine spray upwards to moisten the undersides of the leaves. If the plants are the result of rooting cuttings or layers, the basal shoots will not matter, but if they grow from the stocks of grafted plants, remove them. The buds of your plants are sound, but the plants need a surface mulch of leaf-soil and loam.

Laurel Branch for Examination (E. B. A.).—It is not a fungus on the laurel branches but a mass of adventitious roots. The phenomenon appears to be not uncommon in the cherry laurel, and is mentioned in a paper by A. W. Borthwick in "Notes from the Royal Botanic Gardens, Edinburgh." He does not, however, give any definite explanation, though stating that the branches die and that he had found a fungus present. Probably the roots are an effort to recover made by the plant when weakened for various reasons.

Dwarf Flowering Shrubs ("Hardy Shrubs").—The following kinds are all dwarf-growing, but it is not possible to restrict every one to a certain height without some pruning being done, as soil has varying effects on the plants. Azalea pontica, Escallonia macrantha, Andromeda floribunda, Deutzia gracilis, veronica, Daphne Mezereum, Skimmia japonica and Olearia Haastii, the last-named being suitable for a dry border.

FRUIT GARDEN.

Red Spider on Peach Trees (J. G.).—Red spider is encouraged by a too dry atmosphere. Syringing alone will not stop it spreading, as the leaves dry again from time to time. The general atmosphere must be maintained in an even state of moisture. Red spider breathes through its body, syringing may affect the exposed parts of the body, but not that part pressed against the leaf, so that the insect still lives. Fumes of sulphur will kill it. These fumes can be obtained by sprinkling flowers of sulphur on hot plates, the latter heated to 180°, or on water in vessels heated to almost boiling point. The ammonia arising from a small sprinkling of fresh soot under the trees weekly, and also fresh horse urine judiciously sprinkled on the floor, will, combined, keep the foliage free from this pest.

Pears Cracking (J. K. W.).—The fruits are infected by the scab disease. Very little good would result from anything you may do now, as the disease is too advanced. Collect all leaves as they fall and burn them. Next spring the trees should be syringed with Bordeaux mixture. In the meantime surface dress the soil with good loam after scraping off the top 2ins. of old soil and foreign matter.

Gooseberries Unsatisfactory (H. J. M.).—The fault lies at the roots of the bushes. Probably the soil has been too wet for them this season; but defective root action from some cause is the reason for the berries failing to colour and mature normally. A deep, rather light loam suits the gooseberry best. In such or other well drained soil the fruits grow and finish well, especially when the soil is surface dressed. You should examine the roots and also ascertain whether the bushes are planted too deeply, burying a portion of the stem.

KITCHEN GARDEN.

Celery Rust (J. A.).—The leaves, specimens of which are sent for examination, are badly rusted; there is no sign of celery leaf maggot. The foliage should be well dusted with dry lime, but all efforts to kill the fungus outright this autumn would fail. Next spring you should get a guarantee from the seedsman that the seeds have been treated against rust and grow the plants in a fresh position. The incessant rains have favoured the spread of this disease.

MISCELLANEOUS.

Heating a Small Greenhouse (S. S.).—For a greenhouse so small (12ft. by 8ft.), the ordinary single or double wick burning lamp would be suitable. Then there are the smokeless oil heating stoves similar to the "Valor" kind that burn round wicks. Such stoves will maintain a steady temperature quite high enough for cyclamen. The points to observe are: cleanliness (especially of wick), regulation of burner, and the daily filling up with oil.

Various Questions (Woodgarth).—Presumably you are referring to newly planted roses, in which case there is very little to choose between the two methods. If manure is applied to the rose-beds in November, however, care should be taken to keep it away from the shoots of the trees. Unless the roses are being grown specially for exhibition, we think the practice of mulching with manure better honoured in the breach than the observance, at any rate after the first season. The beds, if made thoroughly well in the first instance, will last for a number of years with a living mulch of violas or other shallow-rooting carpeting plants, and beds "mulched" in this way are infinitely more sightly. Climbing H.P. roses should have any spent wood thinned out after flowering to allow the new growths to ripen up, and these should have their weak tips removed towards the end of March. A properly made herbaceous border needs no mulching with manure, which always harbours slugs and other vermin. Carefully but lightly prick over the surface in November, thin growths of phloxes, helenium, helianthi, Michaelmas daisies and such-like in spring, use the hoe to form a dust-mulch and keep it applied until the advancing growths meet early next summer. Violet runners are rooted just as those of the strawberry. They root freely into loose earth, but a stone on each "wire" will serve to prevent the young plantlets from being disturbed by wind and so forth. The runners should now be rooted and ready to transplant.

Names of Plants.—H. M.—1, Rudbeckia speciosa; 2, R. laciniata Golden Glow.—— D. G.—Rose Mme. L. Messimy.——Mrs. S.—Ægopodium Podagraria, gout weed. The only way to get rid of this weed is to dig it out. Every little bit of root or underground stem left in will grow.

GENERAL BULB GROWERS' SOCIETY OF HAARLEM

THE different floral committees have made the undermentioned awards to gladioli during their sessions July and August, 1924.

FIRST-CLASS CERTIFICATES.—All the following varieties have already an award of the trial garden: Gladiolus Isis, shaded scarlet, thin white line, wide-opened flower, long, straight stem, stout flower; from seeds by Messrs. N. and J. Roozen Brothers, at Heemstede. G. Jacoba van Beyeren, unicoloured violet, long spike, well opened flowers; from seeds by Mr. P. van Deursen at Sassenheim. G. Rose Précose, salmon pink; from seeds by Messrs. Stoutenbeek van Til at Hillegom. G. primulinus Athalia, unicoloured, bright orange; from seeds by Messrs. E. H. Krelage and Son at Haarlem. G. primulinus Citronella, pure citron yellow; from seeds by Messrs. E. H. Krelage and Son at Haarlem. G. primulinus L'Innocence, creamy white, white stamens; from seeds by Mr. H. Carlee at Heemstede. G. primulinus Lætitia, bright salmon pink; from seeds by Messrs. E. H. Krelage and Son at Haarlem. G. primulinus Latonia, soft salmon pink, blot soft yellow, carmine striped; from seeds by Messrs. E. H. Krelage and Son at Haarlem. G. primulinus Rosaura, nearly unicoloured pink-red, little vermilion-red centre, falls somewhat creamy coloured; from seeds by Messrs. E. H. Krelage and Son at Haarlem.

AWARDS OF MERIT.—All the following marked * have already an award of the trial garden: * G. Crimson Glow, dark orange-scarlet, tops of the petals marbled with velvet black lines; imported. G. Fortuna, soft sulphur yellow, big open flowers; from seeds by Mr. W. Pfitzer. * G. Frau Dr. Hauff, bright scarlet with violet line on fall; from seeds by Mr. W. Pfitzer. G. Marconi, very dark purple with velvet shade; from seeds by Mr. W. Pfitzer. G. Mevrouw van Konijnenburgina, blue, with some dark lines, centre almost white; from seeds by Mr. W. Pfitzer. G. Nimrod, soft pink, white centre, top of the petals somewhat notched, creamy yellow blot on the falls. G. Ophelia, apple blossom pink with creamy yellow; from seeds by Mr. W. Pfitzer. G. Orange Beauty, unicoloured orange, petals somewhat notched; from seeds by Mr. C. P. Alkemade at Noordwijk. G. Othello, violet with mauve; from seeds by Mr. W. Pfitzer. G. Paul Pfitzer, purple, with velvet shade on the falls, centre violet; from seeds by Mr. W. Pfitzer. G. Pfitzer's Triumph, stony red with carmine centre, the very big flowers are neatly ranged on a very long and vigorous stem; from seeds by Mr. W. Pfitzer. G. Phanomen, bright soft pink with clear yellow, falls are unusually broad; from seeds by Mr. W. Pfitzer. G. Purest of All, clear pure white, spike well formed, four to five flowers at the same time opened, centre carmine shaded, stamens violet; from seeds by Mr. W. Pfitzer. G. Radio, soft purple; from seeds by Mr. W. Pfitzer. G. Snowmaiden, white, with very faint violet shade, stamens violet; from seeds by Mr. C. P. Alkemade at Noordwijk. G. Thomas Edison, salmon orange with carmine centre; from seeds by Messrs. E. H. Krelage and Son at Haarlem. G. Virginia, warm cherry red; imported from America. G. White Beauty, nearly pure white, big flowers, six to seven at the same time opened, stamens violet, spike well formed; from seeds by Mr. C. P. Alkemade at Noordwijk. G. primulinus Glory, dark orange red, striking primulinus character, big flowers; from seeds by Messrs. E. H. Krelage and Son at Haarlem. G. primulinus Juno, soft salmon with yellow falls and centre; from seeds by Messrs. E. H. Krelage and Son at Haarlem. G. primulinus Old Gold, soft yellow with old gold shade, small flowers; from seeds by Messrs. C. G. van Tubergen, jun., at Haarlem. G. primulinus Scarlet Cardinal, dark velvet scarlet-red; from seeds by Messrs. E. H. Krelage and Son at Haarlem. G. Tubergen's Charm, pure mauve, centre clearer, yellow-green lines on the falls, perpendicular stems about 30 ins. high (shown on June 30th); from seeds by Mr. C. G. van Tubergen, jun., at Haarlem. G. Tubergeni Glow, shaded carmine, falls violet, thin cream-yellow lines, perpendicular stems about 30 ins. high (shown on June 30th); seeds by Messrs. C. G. van Tubergen, jun., at Haarlem.

ORCHARD GARDEN WOODLAND

Vol. LXXXVIII.—No. 2759 Saturday, October 4th, 1924 Price THREEPENCE

The Kelway Colour Border

The formation of actual scenes of beauty with living subjects abounding in interest individually would seem to be a pleasant and worthy amusement, and one as full of dignity as the portrayal of such scenes on paper or canvas.

The late Dean Hole truthfully wrote in *Our Gardens*: "There has been no introduction which has had such happy and universal influence in extending and increasing the enjoyment of a garden as the HERBACEOUS BORDER." One of the first remarks of one's hostess in the country nowadays is, "Would you care to see my new Herbaceous Border?"—or "my new KELWAY Border?"

Send dimensions of space to be filled, and the effect required, stating aspect and soil, and asking any questions.

WRITE NOW to the inventors of Colour Borders:

BARR'S
Beautiful New Seedling NERINES

The most beautiful and easiest grown of Autumn-flowering Bulbs for the Greenhouse.

For autumn decoration in the greenhouse few plants can compare with Nerines for their brilliant and attractive colours. The flowers, produced in umbels of 6 to 24 blooms, are borne on stout stems from 1 to 2 feet high. The colours range from *dark red*, *vivid crimson*, *cerise* and *scarlet* to *salmon*, *coral-rose*, *pink*, *blush* and *white*, many having a glistening lustre which in sunlight gives them the appearance of being dusted with gold or silver. They remain decorative for many weeks, and their beauty may be enjoyed in a sitting-room as well as the greenhouse, if the pots are kept in a sunny window.

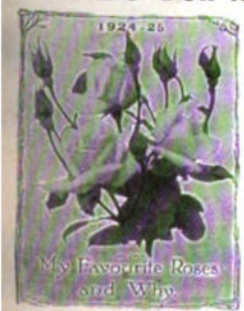
12 in **12** beautiful named varieties .. **42/-, 50/-, 63/-** and **84/-**
6 in **6** " " " .. **18/-, 24/-, 30/-** and **42/-**

SPECIAL LIST ON APPLICATION.

BARR & SONS, 11, 12 & 13, KING STREET, COVENT GARDEN, LONDON, W.C.2.

You will, I hope, forgive my questionable method of arresting your attention. The question itself is really one of moment to you.

Do You know* ? *this Booklet?



If you know it, there is no question at all about it; you send for your copy every year and wouldn't settle your new list without it.

"MY FAVOURITE ROSES AND WHY" is a text book to give any beginner confidence, but it aims to be a YEAR BOOK and a ROSE ANNUAL that will keep an expert up to date.

Of course it is a Catalogue, too—it wouldn't be free and post free if it weren't: but don't hesitate to write for it because you can never send me an order—if I may say so—it isn't your order I'm after, it is your appreciation.

THE ROYAL HORTICULTURAL SOCIETY

ON other pages in this issue will be found a report of the Holland Park Show of the Royal Horticultural Society. There is no doubt that this is one of the most successful of the many brilliant shows which this, the foremost horticultural society in the world, has staged. These shows are, no doubt, its great strength, and it is owing to their popularity that the membership of the Society has increased so rapidly as it has done. On all sides I heard praise of the executive of the Society, and it is not an overstatement to say that the arrangement of the exhibits could not have been bettered. The centre exhibit of Mr. MacDonald's lawns was low on the ground, and then the tiers rose in stages until they culminated in the magnificent tall groups of roses on the one side of the hall and Michaelmas daisies, carnations and hardy plants on the other. The trade, also, deserves every credit for staging such fine groups in such a cruel season as this.

In the past there has been some criticism by Fellows of the R.H.S. that there have not been sufficient classes open to amateurs at the shows held by the Society. Lord Lambourne, the president, announced at the Press luncheon before the show that the R.H.S. was going to hold a special show for amateur exhibits with a large range of prizes in June of next year. In the next issue we hope to publish a full schedule of the different classes, and we sincerely hope that the number of exhibits will be large, for it is by such means as this that the popularity of the Society and of gardening generally will increase.

It seems a pity that with the increase of efficiency at the shows complaints should still be coming in about Wisley for Wisley should come a close second to the shows as regards importance. Several Fellows of the Society mentioned at Holland Park the fact that Wisley was not open on a Sunday. Most Fellows are hard at work during the week and even if they are simply visitors from the country they have often only Sunday in which to examine Wisley at leisure, and yet its gates are rigorously barred. One member of the trade, who to my own knowledge has presented the garden with dozens of plants and who lives a good many miles away, wrote to Wisley to ask if he could see the garden on a Sunday as he was a busy man and it was his one free day in the week, only to meet with a curt refusal; while several amateurs also expressed disgust at the fact that they had been refused admittance. The obvious answer is that to open on a Sunday would cost the Society a certain sum of money either in overtime or in wages for extra staff. This, however, should weigh little with the Council; it would be different if the Society was not in such a flourishing condition financially.

It is common knowledge that affairs have not been running quite as smoothly at Wisley as the Council would like, which is not to be wondered at when Wisley is not under control of the head office nor the head office of Wisley. It is also common knowledge that several months ago a committee of eminent botanists was asked to report upon the situation. No doubt many Fellows of the Society will want to know when the report is going to be published; perhaps the Council will tell us. After all, the status of the Council is very little different from that of directors of a public company who are responsible to the shareholders, and yet they are dictatorial in their attitude to the other Fellows of the Society. The *Times* recently called a recent communique of the Cabinet, in which the only announcement was "the consideration of miscellaneous business," "a classical production." It is about on a par with the information that is given to Fellows of the Society about Wisley. Here is a garden in a good situation, with every chance that money and brains can give, in a position where it is ignored by most Fellows of the Society—and what a chance! Gardeners could be shown everything that appertains to gardening done in the most perfect fashion. It would certainly help to increase the membership of a great Society by several hundreds a year. E. H. M. C.

MICHAELMAS DAISIES

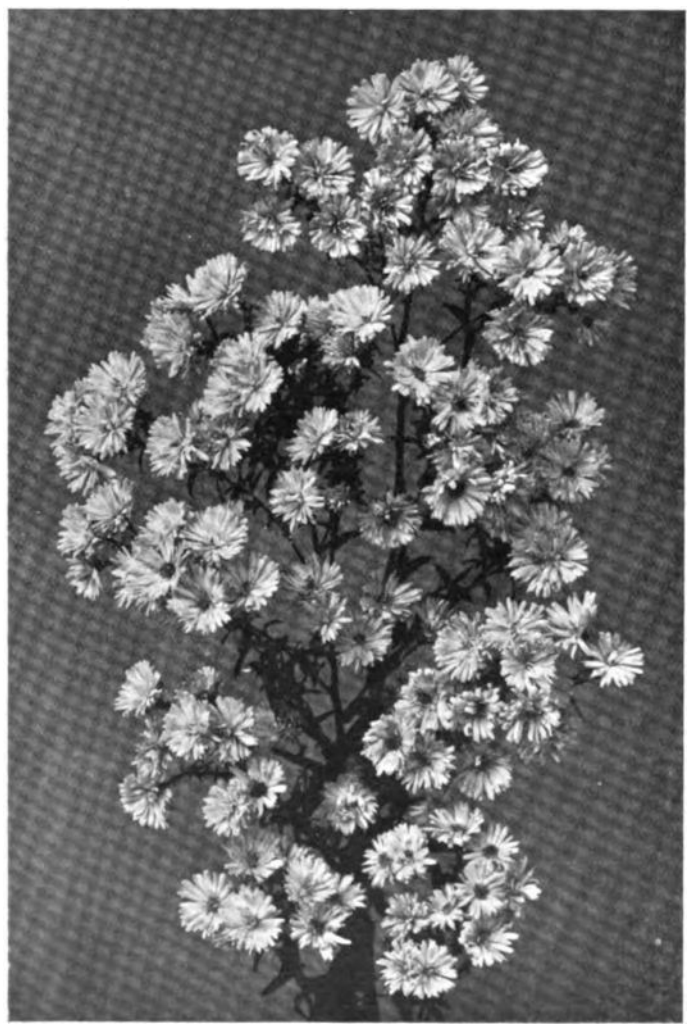
FOR GENERAL HARDINESS AND BEAUTIFUL COLOUR EFFECTS IN THE AUTUMN, MICHAELMAS DAISIES ARE UNSURPASSED.

LIKE Ruskin who once wrote on "Sheepfolds," so Clarence Elliott has written on "Sinks and Pig Troughs." In addition to this, the last-named gentleman has issued a capital catalogue of alpine and herbaceous plants, which I here refer to for the undesigned compliment which he pays the Michaelmas daisy family by excluding it, with the exception of a few species, from its pages, and issuing for it, as only befits its merits, a special list. He favours Mr. Ernest Ballard's productions, but remember

> There are not only Ballard and Jones;
> There are also, friends, Beckett and Bones.

We all have preferences. All that has been written and believed in the past about the sympathy and antipathy of plants may be all moonshine; not so the eternal sympathy and antipathy between individual men and women and certain plants. Why could not Anne, wife of Louis XIII, bear the scent of a rose? Why did Mrs. Siddons have her gloomy walks always edged with one particular purple pansy and no other? Why am I drawn in a special way to Michaelmas daisies? These are rather hard nuts to crack. Perhaps what drew me first of all to Michaelmas daisies was their variety, their hardiness and their friendliness. Of course, I cannot say that I have equal regard for every type and every individual. I have my preferences as I suppose everyone else has. This is why nothing will be said about double-flowered varieties or the Novæ-Angliæ section. Let some wholehearted admirer of these put pen to paper and tell us about them. I do like varieties that keep open in normal English weather and that display clean-cut, round, yellow centres.

I suppose we ought to try to get out of the way of talking about Michaelmas daisies and try to think of them as asters, but we probably never will: for a very similar convention holds good to that in the daffodil world, where the word narcissus is usually appropriated to the poets and tazettas, and daffodil to the rest of the family. Here, aster is usually taken to refer to the dwarf species and Michaelmas daisies to the taller and later-flowering hybrids. These, again, have sectional names, such as Novi-Belgii, Novæ-Angliæ, cordifolius, ericoides and the semi-dwarf Amellus. The newer species are very interesting. I have one from Mount Everest, Porteri, Pattersoni, sub-cœruleus, yunnanensis and Farreri. I wish this last named had flowered, for Farrer's own description raises a very pronounced longing to see its flowers as well as its leaves: "The most glorious aster of the year, a flowering tazzled person of a thousand narrow rays of richest violet; flopping from a central disc of vermilion-orange, a species new to cultivation and the finest yet discovered." Narrow purple flopping petals hanging from a rich brown centre with circles of yellow made of the open flowerets are characteristics of yunnanensis. It seems to be free-flowering, but there is only one bloom on a stalk. It grows about 18ins. high. Sub-cœruleus might be called a glorified alpinus. Porteri forms a dense bush of narrow leaves, slender stems and daisy-like flowers. It grows about the same height as acris nana, and the two might very well be judiciously planted together, or possibly the taller acris might be substituted for nana. Both the two acrises have very narrow purple petals. In our part (Midlands) they both begin to flower about mid-August. Then comes, roughly speaking, the time of the flowering of the Amellus section. Rudolph Goethe is certainly one of the finest purple varieties and has a better habit than King George. Perry's Favourite is a very nice pink, but *the* pink that I have seen has the uncouth name of Wienholtzii.

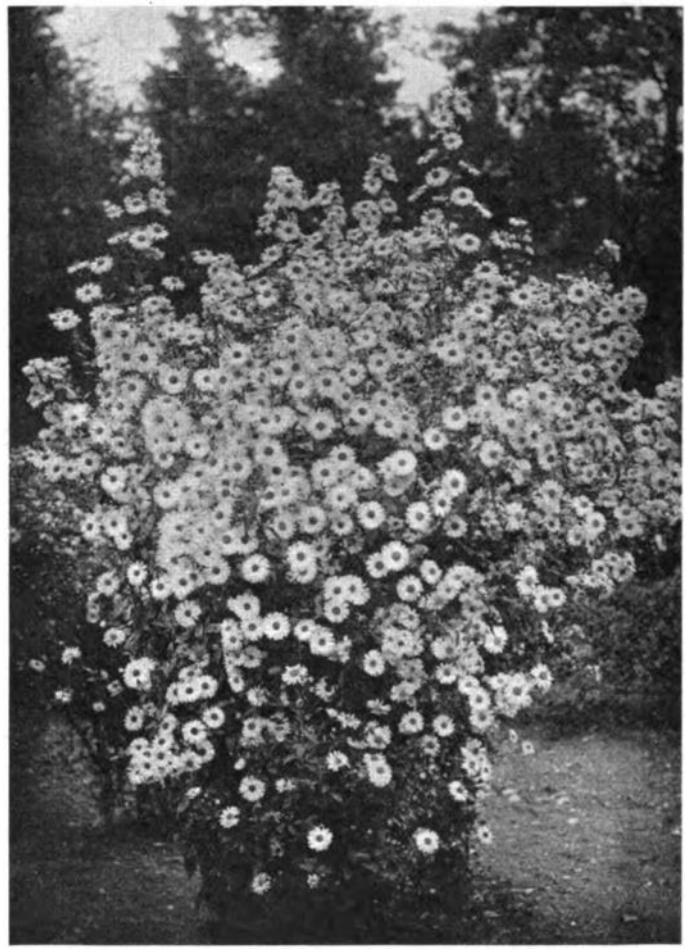


NANCY BALLARD, A VARIETY OF MERIT AND NEAT HABIT, WITH SEMI DOUBLE FLOWERS IN SHADES OF CRIMSON MAUVE.

I now come to what I have called Michaelmas daisies proper, omitting all the Novæ-Angliæ and all the doubles among the Novi-Belgii. I cannot deny that these have their uses, but it made me think furiously when I chanced to hear a zealous salesman pressing a double white on a possible customer because it was so excellent for filling in the bottoms of wreaths! Doubles are, of course, passable in a border if all that is wanted is a splash of far-off colour I think of Bacon's sarcasm about the knots filled with coloured earths. "They be but toyes, you may see as good sights many times in tarts." It is the feeling that when you come to close quarters you will find beautiful flowers instead of mere blobs of colour that makes the whole difference between tart-like and natural beauty. Among the earlier varieties to flower and which I can recommend as being very good are Pioneer (pink), Lavender (pale lavender), Purple Emperor (deep purple), Grey Lady (grey), Bee's Blush (pale pink), Lady Lloyd (rose) Pink Perfection

Digitized by Google

(rose pink), Edith Goodwin (blue-mauve), King of the Belgians (pale mauve), Diana (lilac), Perry's White (white) and Phyllis (pale lavender with a large yellow centre). This last was sent me along with a few others to try. It is a decided acquisition. I like its pretty fresh look and the abundance of its flowers. It has been raised by Mr. T. Bones. My late-flowering dozen are as follows: Nancy Ballard (crimson-mauve) Climax (blue-mauve), Comeliness (pale mauve), Maidenhood (white), Bianca (white, branches like fir tree branches), Louvain (pink), Queen of Colwall (very large pale mauve), Brussels (lavender), Mons (rose), Blue Gem (one of the bluest), Gladys Donellan (lavender) and Sunset (rose). There are a number of species in cultivation, but they are not very often offered for sale by our leading nurserymen. Might I suggest the following for a trial: Tradescanti (very late, white), ericoides diffusus (white), puniceus (blush) and Thomsoni (mauve). So much for names of varieties and species. I now come to matters pertaining to the growth and management of the plants. Where it can be conveniently managed, I like to see a *wide* border filled with nothing but Michaelmas daisies. They never look better than when they are massed together. It is an ideal to aim at, and it is worth a good deal of trouble to carry out. Large beds surrounded with grass are even more pleasing. I always grow as many as I can on single stems. They branch out and grow strong and big, and bear much finer flowers than if the clumps are left undivided. It is only fair to say that there is one drawback, apart from the increased labour which this dividing up entails. When the plants are almost fully developed the side branches are liable to be broken by either wind or heavy rain. I have never been able to devise any plan to make them safe without putting as many, if not more, ties round them than are put round big undivided clumps. Can any reader help me out of this difficulty? Whatever may be thought about this drawback, never can I cease advocating the adoption of taking cuttings annually. There is one reason which outweighs any number of drawbacks. It is a wonderful way of keeping stocks or collections healthy. Like many families of plants which are grown in large quantities Michaelmas daisies have developed a special disease. It shows itself first of all by the gradual yellowing of the foliage from the base upwards, and in the end the whole shoot becomes withered. Providentially, the young new shoots are not affected, and if these are separated and put singly into small pots when growth is beginning, about February or early March, and grown on in cold frames, healthy plants are the result. It is only a small percentage that are otherwise.



A NEW LATE FLOWERING VARIETY, ASTER CLIMAX

Very little need be said about soil. I feel sure it must not be too good. If it is rich, distorted flowers are too numerous. Mildew is a bugbear. I wish I knew exactly what it is that causes it. Can anyone say for certain? JOSEPH JACOB.

A SELECTION OF ORCHIDS

BY GURNEY WILSON.

THIS IS A TIMELY ARTICLE ON ORCHIDS WHICH MAY BE GROWN BY AMATEURS IN AN ORDINARY GREENHOUSE. TO MANY THESE FASCINATING PLANTS MAY HAVE APPEARED TOO DIFFICULT OF CULTIVATION.

IN making a selection of orchids that can be easily grown by the amateur in an ordinary greenhouse, care must be exercised to exclude those requiring a considerable amount of heat, for in these days of economy everybody desires to keep the fuel bill within reasonable limits. Moreover, as there are so many beautiful orchids that succeed admirably with cool-house treatment, and an almost similar number that require no more than a moderate winter temperature of about 60°, it will be seen that amateurs have ample material from which to make a varied selection.

While it is possible to send an order to one of the trade growers for a definite number of plants to fill a house of stated size, leaving the selection to him, it is a far more satisfactory and interesting procedure to select personally the individual plants, picking out those that are particularly attractive to one's taste, for it must be admitted that not all amateurs agree as to what constitutes the finest kind in each respective section.

With regard to species, of which the fixed characters are well known, or at least can be ascertained from one of the text books, it is oftentimes the cheaper method to purchase the plants during the non-flowering period. But with hybrids, the flowers of which generally display a considerable amount of variation, it is much the better way to procure these in flowering condition, unless one is willing to purchase a speculative lot of unflowered seedlings and take the chance of discovering something really fine among them when they yield flowers for the first time. In buying unflowered hybrids consideration should always be given to the parentage, although a certain amount of experience is necessary before being able to make any prophecies as to the results. Consequently, it will be found that higher prices are asked by trade growers for unflowered hybrids derived from parents of recognised merit.

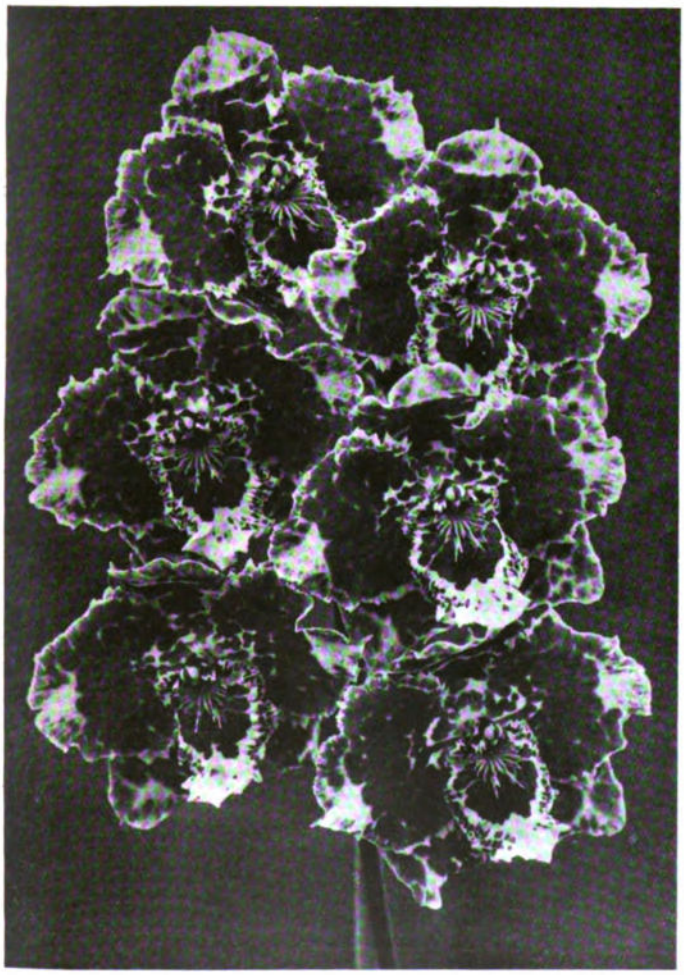
When one considers the attractions of cypripediums, more especially in the autumn and winter months, it is not surprising to find that the majority of amateurs commenced

Digitized by Google

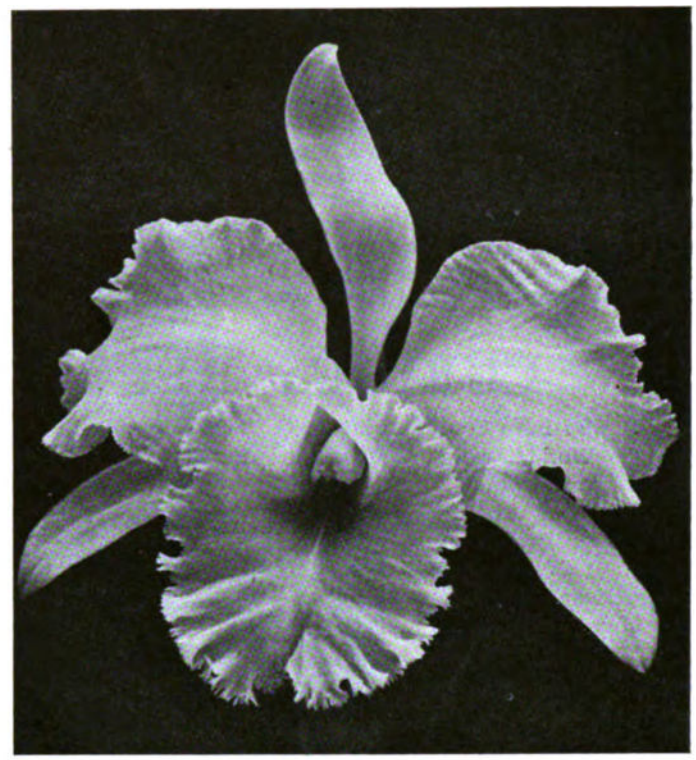
the formation of their collections by the acquisition of a dozen or more of these plants. Taking species first, there exists in C. insigne one of the easiest of all plants to cultivate; anyone can obtain satisfactory results by giving it similar treatment to that accorded maidenhair ferns. Although numerous varieties of C. insigne can be obtained, they may nearly all be put on one side in favour of the Harefield Hall variety, which is a giant of its kind, and C. insigne Sanderæ, a beautiful form yielding flowers of a clear primrose yellow colour that never fails to please.

Of cypripedium hybrids there are thousands to select from, yet none has obtained greater popularity than C. Leeanum (insigne × Spicerianum). Most of the hybrids that include C. Fairrieanum in their parentage are very pretty, and many vigorous kinds have been raised through the use of C. villosum. As a long list of botanical and fancy names is of little use to the commencing amateur, it is advisable for him to select the plants when in flower, and for this purpose the autumn months are specially favourable. When circumstances do not permit a higher temperature than 50° being maintained in winter, care should be taken to select only the cypripediums that readily submit to the cool-house treatment, for some of these plants are not seen at their best unless a minimum temperature of 55° is available.

Cattleyas require the warmth of the sun in summer and a minimum winter temperature of 60°, consequently it is not advisable to attempt their culture when only a cool-house exists. Collections of days gone by were largely composed of species, many of which are difficult to cultivate successfully for any prolonged period. On this account the much stronger constitution owned by the hybrids in this section has brought them into prominence, and they now enjoy no small amount of popularity. For autumn flowering nothing surpasses Cattleya Fabia (aurea × labiata), of mauve-purple colour, and C. Hardyana (aurea × Warscewiczii), of large size and possessing a richly coloured labellum. In both of these,



A TYPICAL SPIKE OF ODONTOGLOSSUM.



BRASSO-CATTLEYA CLIFTONIA ALBENO.

hybrid varieties having pure white sepals and petals can now be obtained, thanks to the enterprise of more than one trade grower.

Owing to the continuous demand for an easily-grown orchid, lælio-cattleyas have been raised in immense quantities. Of the many hundreds of different combinations that have been made between the various lælias and cattleyas, selections may be made that will yield flowers during any desired period of the year. For spring time L.-C. Aphrodite (L. purpurata × C. Mendelii) has long been popular, and so also has L.-C. callistoglossa (L. purpurata × C. Warscewiczii); in fact, almost all hybrids containing L. purpurata in their parentage are noted plants for strong constitution. In the autumn months an equally varied selection may be made, the colours seen in the sepals and petals ranging from pure white to the darkest purple, while that of the labellum is generally of a much richer shade.

Brassavola hybrids consist of numerous combinations of Brassavola Digbyana with the various lælias and cattleyas. They are known respectively as brasso-lælias, brasso-cattleyas and brasso-lælio-cattleyas. Although the addition of B. Digbyana is responsible for an increase in the size of the flower, its chief inheritable character is the deeply fringed edge of the labellum, an attractive feature that is more or less perpetuated in the resulting hybrids. Generally speaking, insufficient colour is the only fault witnessed in brassavola hybrids.

Dendrobiums are fast regaining their former popularity, mainly because their cultural details are now better understood. They are found to grow equally as well in a much lower temperature than our forefathers thought necessary. Imported plants are less frequently seen. In their place many beautiful hybrids of the nobile section have been raised. These plants are particularly adapted to the conditions of an amateur's greenhouse, requiring but little attention during the winter months—their resting season. Activity of the flower-buds commences early in the New Year, and a continuity of bloom may be obtained by giving to a few plants at a time slightly more warmth and moisture.

Although the odontoglossum genus has long been a favourite, and one in which record prices have been made for varieties of outstanding merit, it is only during comparatively recent years that hybrids have been produced in anything like sufficient quantities to enable them to be sold at a figure within the reach of the modest amateur. They require essentially cool-house treatment. In fact, in the best of summer weather it is oftentimes a matter of difficulty to keep the

Digitized by Google

temperature sufficiently low. However, any greenhouse having a minimum winter temperature of 45°, with a few degrees more during the daytime, will yield a welcome supply of delightful flowers, such that as regards elegance and beauty but few other genera can approach.

Odontoglossum crispum will always hold its own as one of the best of useful species, the more so as it has been raised in this country from parents selected on account of their fine floral qualities as well as for their vigorous constitution. On this account the days of imported crispums are never likely to return. Hybrids exist in thousands, and of such floriferous nature that the whole of the genus seems to have been changed from one of difficult culture to that of comparative ease. Here, again, a long list of names would indicate nothing as to the respective plants' true qualities; all that can be said in general is that the genus is eminently adapted to the conditions of an amateur's greenhouse, as well as to the owner's powers of maintaining an orchid collection in first-class style.

It is odontiodas that have added so many pretty tints of scarlet and red to the cool-house section. They have been produced mainly by crossing various odontoglossums with Cochlioda Noetzliana ,and as subsequent crossings reach the flowering stage it is seen that the limits of colour schemes have by no means as yet been reached.

CURIOUS RELATIVES OF PRIMULAS

ALL who have read Farrer's book, "On the Eaves of the World," will remember his excitement on finding a member of "a strange race of primulas that are hardly primulas at all." This was Omphalogramma (primula) viola grandis. He says of it: "Before the leaves unfold to their full development spring up the sturdy fleshy stems, each one of which unfurls one solitary huge flower of rich purple, with a prognathous profile and a throat of quite ridiculous length." This is a very fair description, although not exactly flattering. For many years botanists have been doubtful where to place these odd but beautiful plants. Sometimes they have been placed as a section of the primulas, but at the present moment I believe that they have been segregated in a genus by themselves called omphalogramma. They are all noticeable for their solitary flowers, exceedingly large for the size of the plant, of a deep blue-purple or violet colour, sometimes with a white or yellow throat.

OMPHALOGRAMMA VINCÆFLORA GROWING WILD IN YUNNAN.

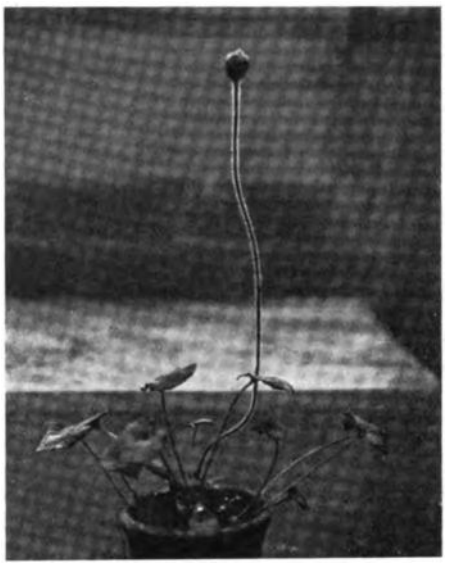
O FARRERI, PERHAPS THE FINEST MEMBER OF THE GENUS, WITH LARGE VIOLET-PURPLE FLOWERS.

At present the genus consists of ten or possibly eleven species, O. Delavayi, O. Souliei = P. Franchetii = P. Engleri, OO. vincæflora, Coxii, Farreri, Forrestii, viola grandis, elegans and minus, all from China or Tibet, and O. Elwesiana from Sikkim. Of these Delavayi, vincæflora, Elwesiana and Farreri have certainly been in cultivation in this country, but they are such tricky and difficult plants that it is impossible to state how many plants exist at the present moment. Indeed, I should hesitate to mention them except that O. Farreri has grown, flowered and is seeding at the present moment in the Royal Botanic Gardens at Edinburgh, which gives a faint hope that we may yet be able to conquer this fascinating genus and be able to coax it to grow in our gardens with comparative ease. Unfortunately, as a rule they appear to be bad seeders, which does not help matters; on the other hand, as will be seen from the illustration on the opposite page, when they do consent to seed the capsule is a noble affair even more out of proportion to the size of the plant than the flower.

After seeing OO. Farreri and Coxii growing in their native habitat and after examining the descriptions of the locality of other members of the genus, I should say that they are exceedingly meticulous on the question of shade, and this has probably been the difficulty in cultivating them in this country. As Sir Isaac Bailey Balfour said at the last primula conference, they thrive best when well flooded with water under ample drainage conditions, although I am not so certain about drainage, for O. Farreri certainly grew in exceedingly marshy ground.

Digitized by Google

At any rate, water is a necessity. On the other hand, all of them, with the possible exception of O. minus, appear to require shade of a peculiar quality. Perhaps I could explain my meaning by detailing the exact situation in which Farrer and I found OO. Farreri and Coxii. Farreri we first found under an overhanging rock with water dripping from the top and a constant seepage underneath. It thrived inside the drip in rather rich peaty soil in a constant state of wet. Later we found it on the borders of marshes always within the first 3 yds. of bamboo creeping down to the marsh edge. O. Coxii was found on rather more rising ground among the thin bamboo and in a constant state of moisture, but, although growing in close proximity, they never intruded on each other, which may prove that Coxii requires better drainage—but Coxii is not in cultivation and is not nearly such a fine plant as Farreri, so his requirements do not matter. The interesting fact is that they invariably faced east and in no case out of several hundreds of plants did we find one exposed to the west. On the first occasion



A WELL-FRUITED SPECIMEN OF O. FARRERI AT THE BOTANIC GARDENS, EDINBURGH.

O. Farreri reposed within 6ft. of the ridge facing east; we searched the other side thoroughly but never a trace. It is obvious that this position was not sought to escape the south-west monsoon, for it would be impossible to imagine a moister place than that in which we found them. The only reason for this behaviour that I can think of is that they strongly object to the evening sun, with the consequent dry atmosphere. If this is so, it might be worth trying them on the edge of boggy ground in a soil mostly made of peat overhung with bushes and not exposed to the west. One of the obvious difficulties would seem to be our warm and damp winter climate, which rots the crown of the plant. The only thing is to place a pane of glass over the top of the plant, which will prevent moisture lodging in the crown and thus helping decay. It will be seen from Mr. Forrest's photograph that O. vincæflora grows in a mixture of bracken and dwarf scrub, no doubt a situation similar to that in which we found Farreri. It is to be hoped that these beautiful things may be coaxed into more general cultivation. E. H. M. Cox.

OLD COTTAGE GARDEN PLANTS

WHICH STILL HOLD THEIR OWN IN FACE OF COUNTLESS NEW VARIETIES AND IMPORTATIONS INTO OUR GARDENS.

AMONG the great variety of plants on the market to-day there are a few notable old-world plants which still hold their own against the countless new varieties that are finding their way into cultivation. There are also many good old plants that are now very rarely offered, and some, I daresay, are not offered at all. Old cottage gardens are extremely interesting from the plant collectors' point of view, as it is possible also to find a good new hybrid that has cropped up and remained undisturbed, the value of it never being suspected. The most interesting gardens are those situated in remote parts of the country, inhabited by hale and hearty old people who have always taken a pride in their garden. It is in these gardens we expect to find large fine clumps of the Madonna lily (Lilium candidum) and the scarlet Turk's cap (Lilium chalcedonicum), not forgetting LL. croceum, testaceum, Martagon, etc.; and where an edging of the garden is made of aged pieces of the now rare Primula auricula, old red dusty miller, a plant of great merit, with its fleshy leaves covered with farina, presenting a white appearance, and large heads of flowers of a quaint brick red colour. And again, there is the old yellow dusty miller, this being a yellow version of the preceding item and also scarce in general collections. But where is the beautiful Primula nivalis (of gardens), known now as P. pubescens alba, with its large snow white heads of blossom? Practically extinct, unless it is in some old Scottish garden, where these plants thrived so well. The primulas referred to are splendid for cool positions in the rock garden, and equally pleasing, if not more so, for the alpine house.

The gold-laced polyanthuses, in all the various forms and colours of brown and gold, are also old-world flowers seldom seen nowadays, but they are quite pretty. Old-established clumps of hepatica, that give us their welcome single and double flowers in January and February, in many shades, are among the best plants we are apt to come across in the old gardens: I daresay the finest old specimens of rosemary (Rosmarinus officinalis) are to be seen against the walls of some old cottages, where they have grown many feet high, and their stout aged stems, clothed with green lichen, make them look all the more picturesque. Then there is the double red sweet william, a very old-fashioned plant, but quite a good one in its way; and also may be found, occasionally, robust old clumps of the double rocket, Hesperus matronalis fl. pl., which is so beautifully fragrant in the evening, and of course makes a fine border plant.

We may look to the cottage windows to see them showing off wonderful old pot plants of geraniums of various sorts, ivy-leaved geraniums and pelargoniums, many of which no doubt are being sought for at the present time. Usually they are seen tied to the ladder arrangement that seemed to be so popular a device in former days; and pots, with curtains of the now scentless musk hanging from them, often adorning a window sill, or by treating it as a hanging plant, it would occupy an old-fashioned flower-pot and would dangle on a chain in front of the window. Probably when a piece of musk is found to be scented once more, it will be discovered in some out-of-the-way old cottage. As regards a few that have turned up as new commercial plants, I first refer to Armeria Vindictive, which originally cropped up in a cottage garden and has become extremely popular, as I daresay it is the deepest and richest crimson yet introduced; it also flowers for a long period, which makes it much more satisfactory. It may be used as an edging plant or, where a fine splash of colour is needed in the rock garden, it surely will admirably supply it. Dianthus F. Millard is another good plant that once occupied a corner of a cottage garden in a remote part of Ireland and is now steadily finding favour where it is seen. It is a good doer and bears abundant large double flowers of a quaint red colour. This plant, among many others, including the preceding item, was launched on the market by Mr. Clarence Elliott. Viola gracilis J. B. Taylor is a charming little plant, evidently a seedling of V. gracilis found in a Yorkshire garden. Its flowers are almost white, being very faintly flushed with lavender, borne profusely throughout the season. It is a first-class plant for the rock garden.

Dianthus Ruth Fischer, also brought from a Yorkshire garden, has large pure white double flowers, sweetly fragrant, and has the advantage of a non-splitting calyx. It is of a sturdy erect habit, and good for cutting. F. BARKER.

Digitized by Google

THE GREAT AUTUMN SHOW

WITHOUT a doubt this was one of the most successful shows ever held by the Royal Horticultural Society. Every exhibitor, large or small, deserves great credit, for no one could imagine worse weather for producing flowers for exhibition purposes, and yet the quality was above the average.

DAHLIAS.

At last year's Autumn Show, Michaelmas daisies were the outstanding feature; this year they were put out of countenance by the dahlias, and it must be owned that the Show gained greatly in effect by the eclipse of the hardier flower, for the "dim religious light" of the Skating Rink is unkind to delicate tones of blue and mauve.

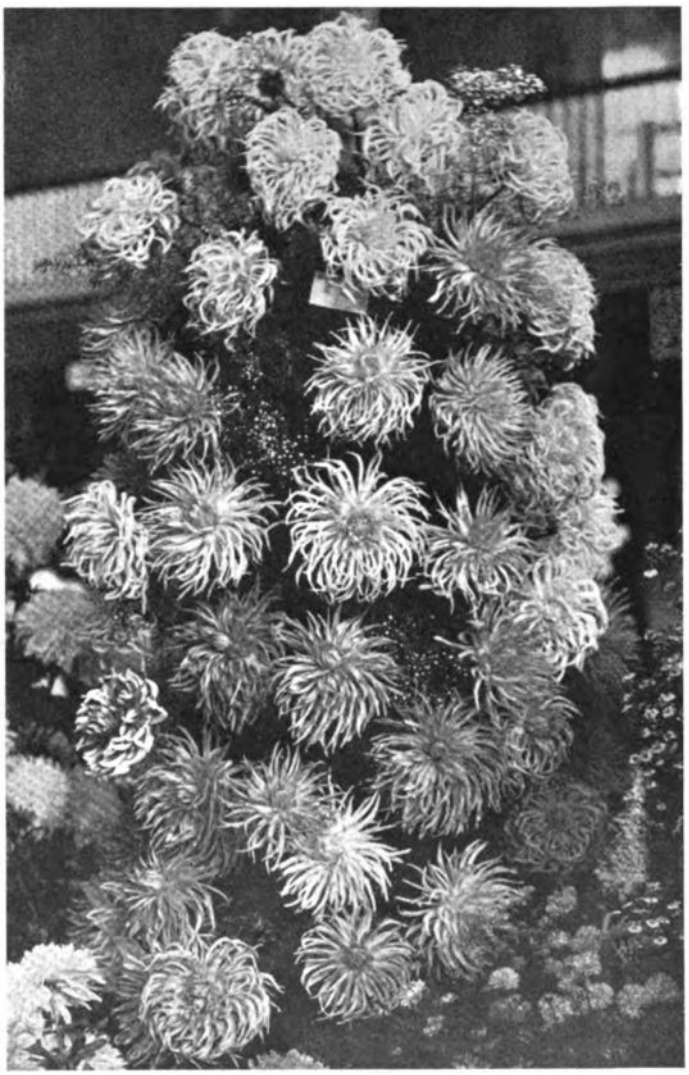
The dahlia exhibits were numerous, and in various ways almost every one was of interest, not only to dahlia "fans" but to all lovers of beautiful flowers. Mr. J. T. West had a very attractive exhibit with a background of large decorative and cactus-flowered sorts and with a great variety of miniature peony-flowered and decorative (garden) singles in front. All tastes were catered for with these, but the following were among the most attractive: Lucius, a brilliant orange decorative single; Helen, rose and yellow; Fashion, rose, crimson and bronze; Lemur, with the strong colouring and very much the appearance of Anemone fulgens; and Rainbow, coppery rose with crimson oculation; the four last belong to the miniature peony or "charm" section.

Mr. J. B. Riding and Messrs. Carter Page and Co. each had representative groups. The most attractive sort on Mr. Riding's stand—at least, we thought so—was Marianne, a delightful camellia-flowered variety of mid-orange colouring, but Lucius was again to the fore, and the well named Crimson Glow, a miniature peony, is first-rate. In Messrs. Carter Page's group we noted a really excellent garden cactus variety of orange-buff colouring called Johannesburg—a sordid name for a beautiful flower, W. Goethe, rose, shaded ruby, belonging to the same section; the well known decorative Orange Boven; and Chamois Rose, a pretty pompon sufficiently described by the name.

Messrs. D. Prior and Son had a wide range of types and colours in a comparatively small space, and the old-fashioned show and fancy types seemed to be attracting favourable notice, as well as their more elegant miniatures, the pompons. Of the last named, Tommy Keith, crimson tipped white; Raider, sulphur; and Daisy, fawn, seemed particularly dainty, while The Maid, a fine white camellia-flowered, would be useful where white flowers are in demand. The prettiest flower on this stand, however, was the miniature peony, Picture, with the ray florets pink at the tips shading to buff as they near the centre, where there is a scarlet zone.

Messrs. W. Treseder and Co. brought a goodly collection from Cardiff, from which we selected Carrie (decorative cactus), orange; Raider (small decorative), orange, shaded ruby; Bacchus, an old but excellent orange pompon; and Vida, an orange-buff camellia-flowered sort.

Mr. Charles Turner's exhibit would have stood spacing out somewhat; some of the most attractive sorts could easily have been overlooked. Marianne we have already noticed; and Crimson Flag, quite the best of the camellia-flowered sorts, we noted in several other places; but a pair of good pompons—Cyril, crimson, and Jessica, gold just touched with crimson—we only noted here, and the same may be said of Trixie, a scarlet miniature peony; Rosie (rose) and Arcturus (fawn zoned scarlet), stars; Dainty, also a star, but very much lighter and more "spidery" than this class usually is, and admirable for table decoration, the colour being rose and gold; Mme. Poirier, a distinct purple and white collarette; and Glut, an atrociously named but useful scarlet decorative. Ladas is the most attractive collarette variety we have seen so far, the colour bright scarlet-crimson and the "collar" of the same tone, but tipped with gold, and the anthers bright gold. Ada Finch—tucked away almost out of sight—is a really beautiful primrose anemone-flowered variety.



A PILLAR OF CACTUS-FLOWERED DAHLIAS IN MESSRS. DICKSON AND ROBINSON'S EXHIBIT.

Messrs. J. Cheal and Sons' exhibit occupied rather less space than usual, but they had many fine blooms of cactus varieties displayed on boards, as well as an array of exhibition and decorative singles, pompons and, of course, the star varieties which they have made so popular. A few good exhibition singles noted here are Hilda, orange yellow and white stripes; Ariel, orange and scarlet; Beacon, citron yellow; and Mary, rose shades. Among the pompons the old rosy purple Nerissa stood out; and Ruby and Darkest of All would have admirers. Mrs. Bigg is an excellent fawn-toned decorative single.

Mr. H. J. Jones had one of his usual big scale exhibits of decorative, show and pompon varieties. This was awarded and well merited a "standard cup"—he won another for the adjacent group of Michaelmas daisies. Almost every basket was either a study in two colours or in two tones of one colour, and all were successful. Surprisingly attractive was a basket of the two show varieties, John Pendereth and Goldfinder, the former orange bronze, the latter soft golden yellow. A decorative (rather out-sized) pompon sort of a vinous purple tone paling to the centre of the globe is novel and pleasing.

Messrs. Dobbie and Co's fine exhibit was especially strong in collarettes, and of these the pick were Glencoe, a bold-petalled crimson; Glen Sannox, similar to the scarlet Novelty, but with only one row of petals, and of better form; Arran, purplish rose and white; and Scarlet Queen, orange scarlet. The well named Dazzle, a miniature peony, and the old orange pompon, Bacchus, were also noted.

For the rest, Messrs. Dickson and Robinson had three good pillars of the decorative, single and cactus types among their Michaelmas daisies; Messrs. Godfrey and Son included some good pompon and other types in a mixed group; and Messrs. Ladhams had quite a lot of a new and wonderfully free-flowering anemone-flowered variety called Attractive. This grows about 2½ft. tall and is of that purplish crimson colouring which would be very attractive in evening light.

ROSES

Not only were roses shown in large quantities but the blooms were so fresh and good that they were the most important feature of the Show. In quality they were fully equal to those at the recent Autumn Show of the National Rose Society.

Although there was a fairly large number of varieties to be seen—nowadays every rose seems to be as good in the autumn as at midsummer—Betty Uprichard, of brilliant orange-shaded carmine colouring,

Digitized by Google

was the rose of the Show and appeared in all the principal collections. W. F. Dreer, which was sent from America somewhere about the same time that Betty Uprichard received the N.R.S. award, was then of quite moderate appearance, but lately it seems to have become acclimatised and to disclose its real beauty. As shown by Messrs. McGredy and Son, Mr. T. P. Edwards, Messrs. D. Prior and Son and others it is quite a desirable variety. Its deep golden sulphur tone with just a touch of peach pink is an uncommon colouring. Messrs. S. McGredy and Son also included goodly quantities of their new sorts Eva Eakins and the pink and gold Mrs. Talbot O'Farrell, the rich golden yellow Mabel Morse; Ethel James, a large single stippled pink with a golden centre, is another of their good novelties.

Besides generous pillars of Betty Uprichard and the yellowish Joanna Bridge, Mr. Elisha J. Hicks had a charming arch of Lady Hillingdon. America, which seems destined to be the pink of all pinks, was shown as large, perfectly formed blooms on long stalks. Golden Emblem and Hoosier Beauty were also admirable.

If Betty Uprichard was the rose of the Show, the largest blooms must have been those of Henry Nevard, which Messrs. Frank Cant and Co. had. These were immense, well formed bright red blooms and passing sweet. They made Padre and Hugh Dickson appear to be quite small. The other Cants—Messrs. B. R. and Sons—had a large vase of Mrs. C. E. Salmon, a lovely soft pink large-flowered single. Rosalind, a flattish pale blush cluster-flowered variety with sun-kissed buds, was uncommon and attractive. Mme. Antoine Mari, which was shown in the same collection and also by Mr. John Mattock, is a desirable fully double H.T. rose of blush shading. Isobel, Ophelia and Mrs. H. Brooks as shown by Mr. Mattock were perfect.

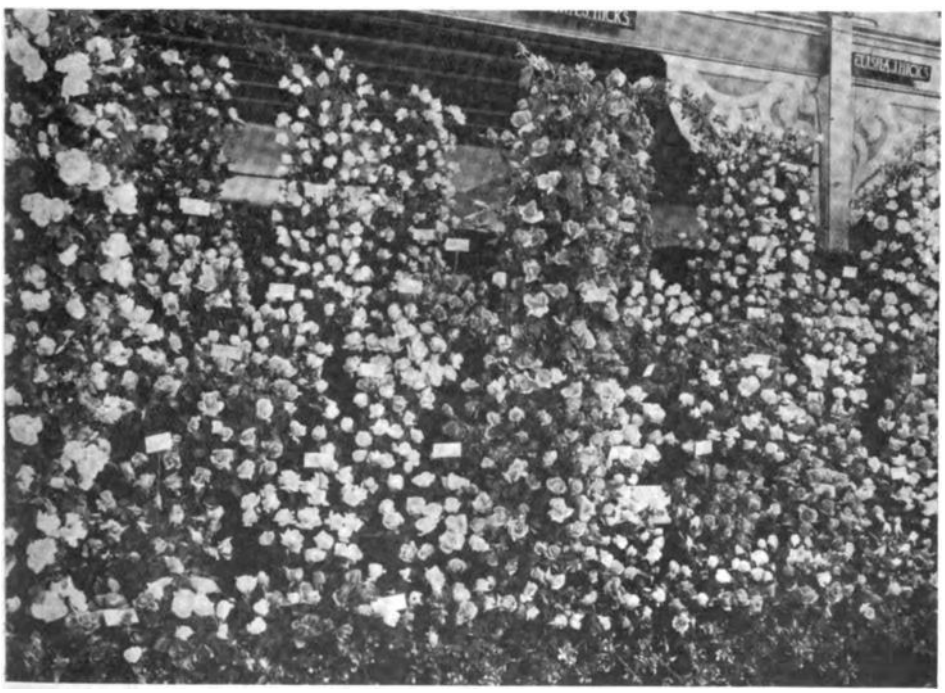
The new cluster-flowered varieties Alice Amos, which has been well likened to a glorified wild rose, and F. Poulsen, of vivid scarlet colour, were shown by Messrs. D. Prior and Son. La Tosca, General McArthur, Los Angeles and Mrs. H. Stevens were also delightful. Besides a lovely stand of Mme. Antoine Mari, Mr. John Mattock showed massed vases of rich glowing blooms of Isobel, Ophelia, Golden Ophelia, Mrs. Henry Bowles and many other desirable roses.

Mr. George Prince always pays due attention to the value of good associations, so that it is a pleasure to inspect his groups. Usually he rather specialises with the fragrant tea varieties, and we suspect that the inclement weather prevented him this time; but the hardier varieties, Golden Emblem, Betty Uprichard, Covent Garden, La Tosca and such were very beautiful.

Emma Wright seems to become even more lovely as the season advances, and this variety was certainly very beautiful in the collection of Messrs. A. J. and C. Allen, who also showed Severine, The Queen Alexandra Rose and Mme. Butterfly in great beauty. A very large collection was finely arranged by Mr. Thomas Robinson, who used nearly all the best varieties. Such rich dark sorts as Col. Oswald Fitzgerald and Etoile de Hollande were prominently placed.

The blush pink roses Mrs. Ambrose Riccardo, Ophelia, Nellie Parker and many other sorts were particularly lovely as shown by Mr. Henry Drew. Messrs. S. Bide and Sons had a quantity of their new climbing Phyllis Bide. The Rev. J. H. Pemberton staged Nur Mahal, Ruth, Vanity, Pax, Cornelia and other free-flowering roses of his own raising. Mr. T. P. Edwards had a good collection in the gallery, where many viewed them undisturbed. Messrs. A. Warner and Son, The Central Garden Supplies and Messrs. Waterer, Son and Crisp all showed good roses. The last named had masses of such valuable sorts as K. of K., Ophelia, Red Letter Day and Covent Garden, with a delightful bordering of many dwarf polyantha varieties.

MAGNIFICENT CLUMPS OF GENTIANS IN MR. CLARENCE ELLIOTT'S EXHIBIT.



GENEROUS PILLARS AND ARCHES OF THE NEW VARIETIES OF ROSES FORMED THE MAIN ATTRACTION ON THE STAND OF MR. ELISHA J. HICKS.

ALPINE AND ROCK PLANTS.

Mr. Clarence Elliott deserves all praise for his most attractive exhibit, which was most excellently displayed. The main items were magnificent clumps of Gentiana sino-ornata and G. Farreri against a background of dwarf Irish junipers. There is little doubt that sino-ornata is proving itself to be an invaluable plant in our gardens, infinitely more so than its paler cousin, G. Farreri.

Messrs. Maxwell and Beale staged a most attractive show of the numerous forms and varieties of hardy heaths. Probably the best colour on this stand was Erica cinerea rosea, which stood out for purity of tone. They also showed alpines, including the neat little Rosa pumila and Erigeron Mrs. F. H. Beale of a fine violet colour.

Mr. Ernest Dixon showed a neat little rock garden design, particularly neat for the small space which it occupied.

Mr. Wood staged a most attractive rock border with fine clumps of Sedum spectabile and Campanula Portenschlagiana. It is difficult at this time of year to make an alpine exhibit attractive, but Mr. Wood succeeded in accomplishing it.

Messrs. Gavin Jones and Ingwersen showed dwarf conifers and alpines in pots, always a good way of making plants look attractive at this time of year, even if only in fol-

Digitized by Google

W. H. Rogers and Son, Limited, staged alpines, including Gaultheria procumbens and a very fine spray of Billardiera longifolia crammed with purple berries. This is an invaluable autumn plant and should be much more used in gardens.

Miss Hopkins showed alpines and a blue annual pea, very decorative but of doubtful hardiness.

TREES AND SHRUBS.

Naturally, at this time of year trees and shrubs are practically limited to evergreens and those which have berries or autumn-coloured foliage. Unfortunately, it was still a little early to show berberis with their berries fully coloured—unfortunate, because this is a magnificent year for berries.

On Messrs. Hillier and Sons' stand, Rosa Moyesii hybrid with its flask-shaped fruits was most noticeable. This is an invaluable rose for grace of habit, flower and fruit. Two vines were also attractive, Vitis Coignetiæ var. Thunbergii and Vitis pulchra (flexuosa major), both with that deep velvety bronze colour which makes their foliage so useful in an autumn garden.

Messrs. Cuthbert staged conifers and a sprinkling of azaleas to show their autumn foliage. Retinospora squarrosa sulphurea is an uncommon ornamental conifer with an attractive yellow tinge to its foliage; while Cupressus Fletcheri was also most attractive.

Mr. Arthur Charlton showed a number of trees and shrubs, including conifers and berberis; but what attracted most attention on his stand were his fine plants of Pernettya mucronata alba, with white berries, and P. mucronata Davis' hybrid, with berries tinged with pink. They showed excellent cultivation, for the bushes were crowded with fruit. This, by the way, is a shrub with male and female plants. It only berries well if there is a male plant growing along with the female plants. Cydonia Maulei with yellow fruits was also shown on this stand.

Messrs. Cheal staged two fine groups of useful shrubs for the autumn. Cotoneaster acutifolia and C. Dialsiana were particularly handsome with their large scarlet berries. Ilex Veitchii and Ligustrum Prattii were also much admired for their neat foliage and habit. Mr. Cheal also showed a fine berberis seedling, so far unnamed, with masses of coral berries.

Messrs. Waterer, Sons and Crisp specialised in hollies on their stand. Many attractive forms of the ordinary Ilex Aquifolium were seen, including tortuosa, a variety with curious twisted leaves. Few people realise the numbers of fine variants of the common holly which can give an added attraction to a garden in winter. They also showed fine bushes of Ilex Perryi, a very fine species with smallish leaves and of good habit.

Mr. Notcutt, who specialises in shrubs, had some particularly fine fruiting sprays of pyrus and cratægus on his stand, which only proved how invaluable these shrubs are both in spring and autumn. Pyrus floribunda purpurea and Cratægus coccinea and C. Crus-galli were laden with fruit, while Colutea cruenta was also attractive.

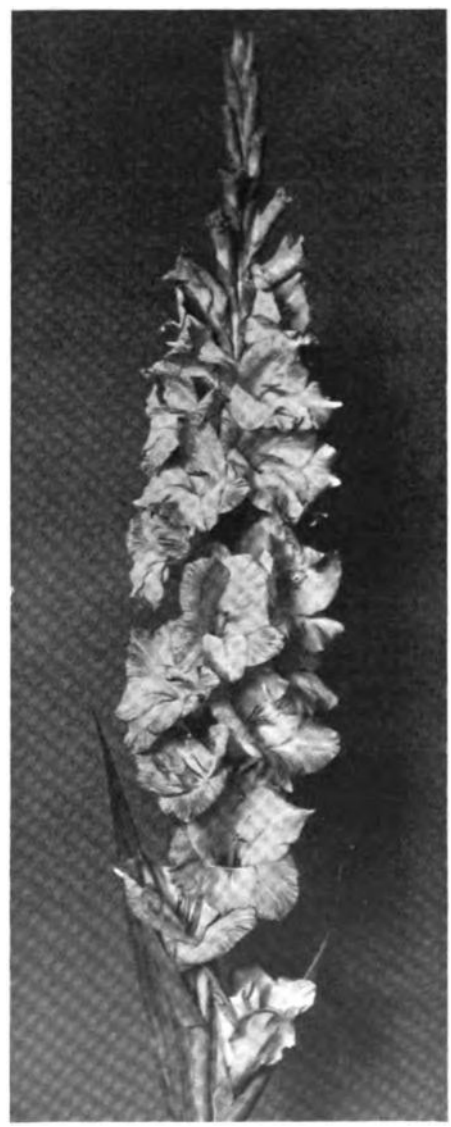
Messrs. Fletcher Brothers showed a fine collection of shrubs and conifers. Among the most noticeable were Grisienia littoralis, Cotoneaster applanata, Taxus baccata Dovastonii and Abies concolor violacea, all well grown and fine specimens.

Messrs. Bowell and Skarratt staged hardy plants and autumn shrubs.

Mr. Reuthe, as usual, had a fine selection of rhododendron species and hybrids on his stand, in addition to hardy plants.

Messrs. Wallace staged a mixed stand of autumn shrubs intermingled with lilies, for which this firm is so famous, kniphophias and Michaelmas daisies.

The best place to see the clematis was from the Music Gallery. There one could look down on the two splendid collections and admire the lovely, large, saucer-like blooms, which Messrs. G. Jackman and Sons and Messrs. L. R. Russell, Limited, grow so well. In the morning of the first day, when rain was falling outside and the light inside was dull, it was the white and the light-coloured sorts that gave one the impression of being the most desirable. One remembered that when the "Evening Garden" correspondence held the readers' attention several thoughtful writers insisted on the value of white and pale-coloured flowers for the late evening enjoyment of the



A FINE SPIKE OF GLADIOLUS SPITFIRE SHOWN BY MESSRS. DOBBIE & CO.

garden, and one agreed with them. Among such varieties were Marie Bousselet (a white flower which has a light lavender bar), Fairy Queen, Mrs. Cholmondley and even the silvery blue Desfosse. But later in the day, when the sun burst through the gloom and flooded the hall with brilliance, the paler varieties lost, for the nonce, their value and the vivid colours were the most satisfying and desirable. Crimson King, of almost transparent "crimsonness," if one may coin the word, was the most gorgeously beautiful of all the many beautiful varieties in the two collections. Even Ville de Lyon, of more solid crimson colour, paled before it. The rosy lavender Comtesse de Bouchard, the azure blue Lady Northcliffe and the dark blue Daniel Durondeau were also very beautiful.

GLADIOLI.

Although the season is far spent, there were many good exhibits of gladioli. Decidedly the best spikes were shown by Messrs. Dobbie and Co., whose exhibit was of "Pedigree Seedlings" of superb quality. A great range of delightful colourings was displayed; the spikes were exceptionally large and the fine "pips" perfectly disposed. It was noticeable that this strain carried more fully expanded flowers on the spikes than is usual—one spike had no fewer than seventeen good blooms open.

Messrs. Austin and McAslan showed many good sorts of high quality. Glory of Nordwijk, creamy yellow; Ivory, L'Immaculée, white; Venus, blush; and the glowing Prosperine are a few examples.

Messrs. R. H. Bath, Limited, had a large collection of particularly good spikes. Cydonia, deep amaranth; Nora, light purple over cream ground; Chris, crimson terra-cotta; Baron Hulot, blue; and Willy Wigmer, white with crimson blotch were the pick of the large-flowered sorts; while Alice Tiplady, L'Orillon and Topsy, orange shade primulinus hybrids, were all of great value.

Messrs. Lowe and Gibson staged a number of uncommon seedlings, both of the large-flowered and the primulinus types.

Mr. A. Edwards displayed Lily, Dorothy, La Saviere, Dixmude and other sorts.

STOVE AND GREENHOUSE PLANTS.

There were no elegant groups of miscellaneous hothouse plants or magnificent specimens such as were a great feature of some of the large provincial shows a month since. The nearest approach were the large circular groups so well arranged by Messrs. Sutton and Sons and Messrs. Carter and Co. These were of entirely different character and equally successful, yet alike in that both firms contented themselves with one kind of plant for their main display. Messrs. Carter and Co. used a large number of liliums and made a fascinating group. In the centre, surmounted by a graceful palm, they arranged Lilium lancifolium Melpomene, next came the rather larger-flowered variety magnificum, surrounded by a belt of the blue Browallia speciosa major. At studied intervals were placed occasional plants of the fragrant Lilium auratum or a slender palm.

Gloxinias were used by Messrs. Sutton and Sons, and of these they had 700 perfect little plants in full bloom. The general idea was radiating segments of a raised circle with alternating high and low panels, and each low panel contained a handsome gilt basket of gloxinias. One variety only was used in a panel, and the chief sorts were Duchess of York, blue with a white rim; Duke of York, red, edged with white; Meteor, a large frilled bloom of brilliant scarlet with a white throat; Royal Crimson, of rich velvety colour; King George, a scarlet self; and Her Majesty, pure white.

A magnificent collection of double-flowered tuberous-rooted begonias was contributed by Messrs. Blackmore and Langdon. The blooms were fully as large as camellias, but were free from any suggestion of coarseness. Among the many sorts we especially noted Grand Monarch, deep crimson; General Joffre, brilliant red; John Mercer, orange scarlet; Lord Lambourne, deep orange; and Lady Cory, pale orange.

Messrs. Stuart Low and Co. had an interesting little collection of uncommon greenhouse plants. Eustoma Russellianum, a hardy annual from round about Texas, which bears, on erect stems a foot or so high,

Digitized by Google

large erect bell-like blooms of lavender-purple colour; Mutisia decurrens, a perennial for a shady wall, has glaucous foliage and heads of deep orange-coloured flowers; Hæmanthus puniceus and a scarlet Bouvardia are examples of the plants shown.

A handsome group of palms was displayed by Messrs. Robert Green, Limited. The long arching leaves of a tall pair of Kentia Dumoniana hung over well grown specimens of Phœnix Rœbelinii, Arenga saccharifera, Chamærops histrix, Cocos australis and similar species.

Brilliant trusses of zonal pelargoniums, shown by Mr. R. J. Case, attracted a deal of attention. His chief double-flowered varieties are Baronne A. de Rothschild, Emperor Nicholas, Lady Churchill and Pasteur; while among the singles were A. J. Macself, Exquisite, Fascination, His Majesty, Mars, Mrs. F. H. Wright, Mrs. V. Slade and Sensation.

Cacti and allied plants were shown by Miss S. S. Thompson and Mr. S. Smith. For the most part they were small plants and Opuntias, Philocereus senilis, mamillarias in variety, Crassula falcata, cotyledons, euphorbias and mesembryanthemums.

CARNATIONS.

Perpetual-flowered carnations were well staged by Mr. C. Engelmann, Messrs. Allwood Brothers and Messrs. Stuart Low and Co. The first-mentioned had a large and beautiful group of Saffron, with such other standard varieties as Laddie, Tarzan, Benoni, Pink Delight and Nigger. The beautiful and well named Chintz was noted both here and on Messrs. Allwood's exhibit. Messrs. Stuart Low's "cars" occupied a corner of a large exhibit chiefly devoted to orchids, but they had White Pearl, Eileen Low and the orange Sheila Greer in fine form.

Messrs. Allwood's perpetuals included masses of Wivelsfield Apricot, and of the rest the crimson Topsy and the brilliant scarlet Edward Allwood were well to the fore. In a separate group they displayed the hardy border perpetuals and Allwoodii. The most attractive of the latter was the pale salmon-pink Sybil; while the range of colours now possessed by the border perpetuals can be gathered from the following list of names: Sussex Crimson, Sussex Purple, Sussex Red, Sussex Avondale (deep salmon), Sussex Rosalind (brick red and citron flake), Sussex Supreme (like Enchantress Supreme of the perpetuals proper), Sussex Leander (almost scarlet), Sussex Beauty (heliotrope) and Sussex Pink. This type is unquestionably gaining fast in popularity.

CHRYSANTHEMUMS.

As befitted the season, all the chrysanthemums were from plants grown in the open border, and so there was to be seen a selection of the best sorts for autumn flowering. The chief exhibitors were Messrs. Wm. Wells and Co., Messrs. Keith Luxford and Co. and Mr. Wm. Yandell, and they all showed many vases of disbudded varieties and of naturally grown sprays. Of the former, Lichfield Purple, Crimson Pride, La Pactole, Kathleen Wells (the new large white), Eden (mauve incurved tipped with gold), Uxbridge Pink, Bronze Cranfordia, Lichfield Pink and Almirante are a good selection. Those grown as sprays were the more numerous, and of the several early-flowering singles Redwing and the yellow September Gem had considerable merits as decorative flowers. Those of Japanese type included Verona (bright crimson), Horace Martin, Goacher's Crimson (a variety very largely grown for the market), Normandie (of lovely soft pink colour and very free-flowering), Bronze Normandie, Dick Barnes (dark crimson, which is not quite so decorative when just

CARNATIONS IN VASES WERE SHOWN BY MESSRS. ALLWOOD BROS.

Digitized by Google

passed maturity), Shrapnel (of intense red colouring) and Golden Gleam.

Messrs. G. Jackman and Sons had Harvester (pale golden bronze), Framfield White, Goacher's Crimson and other sorts associated with their clematis and mixed border flowers.

BORDER FLOWERS.

White Michaelmas daisies were so numerous as to require a section to themselves. The brightest colour among the hardy border flowers was supplied by the glowing spikes of tritomas.

Messrs. Isaac House and Sons had a glorious group composed solely of magnificent spikes of Mount Etna, which variety is indeed of fiery volcanic colour and the spikes unusually large.

A good selection of tritomas was associated with various hardy flowers by Messrs. G. Gibson and Co., who also showed Lilium tigrinum varieties and several valuable aconitums.

Liliums were also prominently shown by Messrs. K. and G. Cuthbert, who used them at the corners of their large group of hardy shrubs. Goodly quantities of Lilium rubrum and L. Fortunei rising above bushes of Azalea mollis-sinensis hybrids and Azalea occidentalis in the full glory of autumn colouring were singularly effective.

Pentstemons and herbaceous phloxes were the chief flowers staged by Messrs. J. Forbes, Limited, who displayed many of the very best named varieties. Of a great many pentstemons the brightest and best was Castle Forbes, a tall, graceful spike of rich red flowers which have a white tube.

This season, pyrethrums have been flowering almost continuously since the spring, so it was not surprising to see this valuable flower in various collections. Most were displayed by Messrs. Rich and Co., who also had Gaillardia Sunshine, a splendid large flower of good form and substance and clear golden colour. They included the elegant Astrantia major, which also was to be seen in the little rock garden of Mr. F. G. Wood, who in his general collection of border plants gave the central position to a mass of the lovely Lavatera Olbia.

Although it is quite an old plant, Salvia uliginosa is not often grown outside botanic gardens, but Messrs. G. Jackman and Sons had a number of tall stems of its beautiful blue flowers. This hardy salvia is of easy cultivation and seems equally good in a dry season as it is this year. Secondary spikes of excellent delphiniums were well arranged by Mr. T. Carlile, whose collection also included spikes of a glowing golden lupin and Phlox Mrs. Milly van Hoboken, a new variety bearing large flowers of a lovely soft pink colour.

The perennial lobelias in which Messrs. B. Ladhams, Limited, specialise were freely shown by them. Of their many varieties we liked best B. Ladhams, a larger and brighter L. cardinalis, Purple King, Salmon Queen and Rose Queen.

Besides their handsome tritomas, Messrs. Isaac House and Sons showed their almost ever-blooming Scabiosa caucasica in many charming varieties of all possible shades of blue and of mauve. A most desirable novelty in scabiosas is their S. columbaria rosea. It is a most charming shade of rose pink, and Mr. House tells us that it is equally as floriferous as the caucasica varieties. It should be treated in the same manner as with pentstemons.

Excellent double Cambrian poppies, both of yellow and of orange colour, were shown by Messrs. W. H. Rogers and Son. Mr. H. Hemsley had a good assortment of general border flowers, Mr. H. Yandell staged many of his violas, and Messrs. W. J. Godfrey and Son showed, with other flowers, Scabiosa Pride of Exmouth.

The Central Garden Supplies included the fascinating Verbena venosa in an attractive little group, while Messrs. Reamsbottom and Co. continued their long series of exhibits of splendid St. Brigid anemones.

Violets as large and as fresh and fragrant as in the spring were shown in large quantities by Mr. J. J. Kettle and Mr. B. Pinney.

In the gallery there was an uncommon and very interesting exhibit of dried flowers arranged by the French Intensive Gardens. A great many species of flowers and grasses had been treated, and they all retained their natural charm and grace with the addition of, if not imperishability, at least a greatly prolonged period of usefulness. Among the many flowers so treated were Echinops Ritro, Accroclinium roseum, Helichrysum lanatum and Rhodanthe maculata. Among the many grasses, which were gathered when the plumes were of almost full size and just before the pollen ripened, many varieties of agrostis, Lamarkia aurea, Hordeum jubatum and Helipterum Humboldtianum were very successful.

FRUIT AND VEGETABLES.

Although the special show of fruit and vegetables was fixed for a fortnight later, or, perhaps, in anticipation of it, fruit was freely exhibited at this Autumn Show. A welcome innovation was the number of exhibitors who brought growing trees of various fruits, thus enabling the visitors to judge of their habit and, to a certain extent, fruitfulness. In this form and also as gathered fruits apples, naturally, predominated, and nearly all the fruits so shown were gorgeously coloured. This was particularly noticeable with Cox's Orange Pippin, which almost vied with Gascoyne's Scarlet, a variety famed among growers for its high colour.

On a floor space Mr. J. C. Allgrove set out a number of well grown, balanced trees bearing goodly crops of apples, peaches and plums. Apple S. T. Wright, a variety which received an award of merit about a dozen years ago, was perhaps a shade too large to be an ideal table fruit, but the wonderfully attractive colour compensated for this. A large fan-shaped Peach Princess of Wales was perfectly trained and well fruited, as also were two large standards of a seedling peach. The plums were chiefly Guthrie's Latest Green, Golden Transparent, Late Orange and Jefferson's. Among the many baskets of gathered fruits were to be seen St. Everard, Rival, Warner's and the Rev. W. Wilks apples; Royal George peaches; and such plums as Grand Duke, Monarch and President.

Special prominence was given by Messrs. Waterer, Son and Crisp to their new Apple John Waterer, of which three or four bushes in full bearing and a large basket of fruits were shown. It is a large culinary apple, much like a clear-skinned Warner's King, but is said to keep well into May. The shapely yellowish fruits have a good appearance and it is claimed that it is a splendid cooker. Other apple trees included Charles Ross, Emperor Alexander, Cox's Orange Pippin and Washington. They also had many varieties of figs as growing plants, and among them were White Ischia, Brown Turkey and Negro Largo.

In another part of the hall Messrs. T. Rivers and Son staged admirably grown trees of Peasgood's Nonsuch, Gascoyne's Scarlet and Cox's Orange Pippin apples, President plum and Sea Eagle peach, and all were as perfect as human skill could make them. Besides these fruiting trees Messrs. Rivers had baskets filled with shapely fruits.

A large collection of gathered apples and pears was shown by the Barnham Nurseries Company. The dessert apples included typical specimens of Worcester Pearmain, Lady Sudeley, Cox's Pomona, Allington Pippin, Ribston Pippin and The Houblon while chief among the many culinary varieties were Peasgood's Nonsuch and Grenadier. The pears included excellent fruits of Doyenne du Comice, St. Lukes, Conference, Verulam, Beurré Hardy, Marguerite Marillat and Triomphe de Vienne.

The success of the training at the Studley Horticultural College was fully evident in the high quality of the fruit the students exhibited, and their method of arrangement was also admirable. Pears were a very important feature of the exhibit, and while all the dishes were of typical fruit of even sizes, they were most remarkable for their highly attractive colouring. Souvenir du Congrés, Beurré Hardy, Beurré Superfin and Doyenne du Comice were especially prominent in this respect, though in a competitive show they would have won a high place on all points. Other pears of note were Pitmaston Duchess, Marguerite Marillat, Santa Claus and Beurré Bossoch. The dessert apples were of the ideal small size and mostly of glorious colouring. Besides a good selection of these and of the culinary varieties, several baskets of nuts were shown.

Apple Hounslow Wonder, a useful dessert variety of good medium size and delicately attractive colour, was included by Messrs. S. Spooner and Sons in their exhibit. Duchess' Favourite, Worcester Pearmain and Baumann's Red Reinette were intensely coloured. High colour was also present on many of the table apples shown by Messrs. Laxton Brothers. The Premier, Worcester Pearmain and The Houblon were most brilliant. Golden Spire and large shapely fruits of Rev. W. Wilks were, in contrast, of glowing golden hue.

Messrs. Daniel Brothers, had in front of their apples and pears a quantity of gathered bunches of their September Black. That the berries in this moist season should still be firm and plump speaks eloquently of its long-keeping qualities. The apples included Charles Ross, Cox's Orange Pippin, Worcester Pearmain and Ellison's Orange among dessert varieties, and Lord Derby, Bramley's, Emperor Alexander and Peasgood's Nonsuch of the culinary sorts. They also showed equally good dishes of pears Williams' Bon Chrétien, Marguerite Marillat, Conference and Triomphe de Vienne.

A very tastefully arranged collection of high quality apples and pears was made by Messrs. G. Bunyard and Co. Louise Bonne of Jersey, Conference and Triomphe de Vienne as examples of the pears were perfectly typical. The Queen, Cellini Pippin, Ribston Pippin, Lady Sudeley, Worcester Pearmain and Egremont Russet, to name only a few of their apples, were all that could be desired.

A large trained specimen of his Worcester Berry, densely laden with fruits, filled the centre of an exhibit by Mr. E. Parsons. This fruit, which was first sent out about a dozen years ago, is the result of a cross between a black currant and a gooseberry. It is rather larger than a big black currant, of pleasant flavour and said to be a very good cooker. Apple Madresfield Court, which received an award of merit at the same time, was also well shown. This is a somewhat angular fruit, well coloured, of firm yellowish flesh, high flavour and a long keeper.

There was a small collection of very meritorious vegetables grown by the pupils of the Guild of Blind Gardeners, whose headquarters are at 72, Edith Road, W.14. They staged quite good potatoes, turnips, carrots, marrows and mustard and cress. Besides this the only collection of vegetables was by the Hon. Vicary Gibbs. Almost countless collections of high-class vegetables have been exhibited from the Aldenham House Gardens, and superb quality is always confidently expected, but the general opinion of the experts was that on the present occasion Mr. Edwin Beckett had beaten himself. It was a large collection, arranged in the best

Digitized by Google

exhibition manner. Where, as in this case, every item was as near to perfection as is possible, selection of dishes for special mention is a difficult matter. Probably the peas were the most meritorious. Quantities of Quite Content, Sutton's Selected, Gladstone, Early Giant and Duchess of Albany were displayed. A special point about these peas was not so much their size and perfect shape but the green "bloom" which enveloped each pod. What care must have been taken in gathering, packing and in arrangement to preserve this fascinating bloom! Every seasonable vegetable was represented in the best possible manner, including the, to the average person in this country, uncommon sugar corn, of which fat pods of Sutton's Early Dwarf were shown. This magnificent collection of vegetables was awarded the Coronation Cup as being the most meritorious exhibit in the Show.

NEW & RARE PLANTS.

ASTER MAID OF ATHENS.—This is a fairly large-flowered, nearly double Michaelmas daisy made of narrow florets of light mauve colour. Award of merit. Shown by Mr. E. Ballard.

ASTER ROYAL BLUE.—The rich dark blue colour of this Michaelmas daisy is valuable, but we fear the stiff, erect, bunched habit of the flowers will not appeal to the majority. Award of merit. Shown by Mr. E. Ballard.

ASTER THORA PERRY.—The plant which was shown indicated a good dwarf spreading habit. The large flowers are a trifle shaggy in make up, but graceful and of lilac blush shade. Award of merit. Shown by Mr. Amos Perry.

CHRYSANTHEMUM BRILLIANCY. (See "New Chrysanthemums.") Award of merit. Shown by Mr. H. Woolman.

C. CISSBURY YELLOW.—A valuable incurved variety of good compact habit and market size. The colour is a good rich yellow. Award of merit. Shown by Mr. S. Aish.

C. ILLUMINATOR.—A medium-sized border Japanese variety of slightly loose habit and rich amaranth colour. Award of merit. Shown by Mr. H. Woolman.

C. KATHLEEN WELLS.—The blooms of this variety were obviously cut from pot-grown plants. It is a splendid white Japanese variety of quite large size for the season. Award of merit. Shown by Messrs. Wells and Co.

C. LICHFIELD PEACH.—A most charming early-flowering border variety which is also well worth growing in pots for conservatory decoration. It is a compact flower made up of dainty narrow florets which droop gracefully. The colour is the silvery pink of peach blossom grown under glass when it first opens. Award of merit. Shown by Mr. W. H. Thorpe.

C. SALMON PROFUSION.—(See "New Chrysanthemums.") Award of merit. Shown by Mr. W. Yandell.

C. SILVER QUEEN.—(See "New Chrysanthemums.") Award of merit. Shown by Mr. H. Woolman.

EUSTOMA RUSSELLIANUM THE OXFORD.—This is a richer coloured—quite Oxford blue—variety of an annual plant introduced from "Nebraska to Texas" in 1804. Although said to be hardy, it is usually grown in pots of light, moderately rich soil for conservatory decoration, but is far from being common. Generally it makes a slender, single-stemmed, erect plant a foot or so high, surmounted by relatively large, upright flowers somewhat of campanula shape. The small leaves are of glaucous hue. It is a beautiful and uncommon plant, well worth growing for the cool greenhouse, and if care is exercised in watering, presents no cultural difficulties. Award of merit. Shown by Mr. C. J. Ellis.

GLADIOLUS NORA TOOMER.—A well disposed spike of large rich orange-coloured flowers which have a carmine blotch on each of the two lower segments. Award of merit. Shown by the Orpington Nurseries Company.

POTENTILLA DAHURICA MANCHURICA.—A goodly pan of this pretty little prostrate shrub was shown. The sturdy foliage is greyish green and the relatively large flowers are pure white. Award of merit. Shown by Mr. Amos Perry.

A BEAUTIFUL FRUITING SPRAY OF PYRUS PINNATIFIDA, A NATURAL HYBRID.

POTENTILLA FARRERI PROSTRATA.—Although a little more robust than the foregoing, this is also quite a low-growing little shrub. The pale green foliage is narrow and the large flowers are almost of buttercup yellow colour. Award of merit. Shown by Mr. Amos Perry.

POLYSTICHUM ANGULARE DIVISILOBUM NITESCENS GRANDE.—Despite the forbidding length of name this is a handsome hardy fern. The delicately divided pale green fronds are almost 3ft. long and perfectly proportioned. Award of merit. Shown by Mr. Amos Perry.

PYRUS PINNATIFIDA.—There is a certain amount of mystery attached to this handsome hardy tree. It is generally supposed to be a natural hybrid between Pyrus intermedia and P. Aucuparia. It grows wild in West and Central Europe, though very occasionally in England. It does quite well on chalky soils and also grows vigorously on clay. At its best it is a rounded, slightly fastigiate tree 30ft. in height. The dark green leaves are nicely divided at the basal half and become well coloured in late autumn. The whitish flowers are quite attractive, and these are succeeded by clusters of vivid red fruits, rather larger than those of the mountain ash, which make the tree very handsome just now. Award of merit. Shown by Mr. G. Codrington.

A vase of arctotis seedlings raised by Mrs. Lloyd Edwards from seed sent from Cape Colony was submitted to the Floral Committee, but for some reason they do not appear to have attracted any attention. The typical yellow form predominated, but there were several flowers which appealed to us in their improved shape and rich colour. One was of scarlet terra-cotta shade with an orange zone, another was similar but a trifle lighter in the ray colour, while a third was a very large bloom of bright mauve colour with a creamy yellow zone.

NEW DAHLIAS.

The Joint Dahlia Committee found an enormous number of seedling dahlias awaiting judgment. Of these they selected nineteen "For Trial at Wisley," but we are inclined to the opinion that only the most optimistic would expect to see some of them in the future. We selected the following as being worthy of mention:

AMY.—A beautiful miniature peony of pink colour overlying a golden yellow ground. The centre is clear from the pink, giving a golden zone. Shown by Messrs. J. Burrell and Co.

FLAME.—A large miniature peony which is almost a single. It is a bold flower of glowing orange colour. Shown by Messrs. J. Burrell and Co.

FANCIFUL.—A neat single of orange shaded fawn colours. Shown by Messrs. J. Burrell and Co.

MRS. W. R. DYKES.—A well formed miniature peony of brilliant rosy mauve colour. Shown by Messrs. J. Cheal and Sons.

MURIEL.—A miniature peony of the same lovely colouring as in Amy, but smaller and of more rounded shape. Shown by Messrs. J. Burrell and Co.

PINK COLTNESS GEM.—This is a pinkish counterpart of the popular bedding dahlia but the colour is at present too washy. No doubt a couple of years' further selection will bring the desired colour. Shown by Mr. T. Hay.

WESSEX.—A perfectly round single dahlia of good substance and intense crimson colour. Shown by Mr. A. J. Cobb.

WINNIFRED.—A rich orange single with a carmine zone. Shown by Messrs. J. Burrell and Co.

NEW CHRYSANTHEMUMS.

The Floral Committee of the National Chrysanthemum Society met at the Holland Park Hall, London, on September 22nd last, to consider the merits of a number of seedling outdoor chrysanthemums. Five novelties received awards, and the committee expressed the desire to "see again." Brightness, a rather small but vivid crimson Japanese variety, shown by Mr. H. Woolman; and

Digitized by Google

Phœnix, a tiny narrow-petalled Japanese variety of intense colouring, shown by Messrs. Scott and Wickham.

BRILLIANCY.—This is a free-flowering sort of Source d'Or type but with broader florets, more rounded in shape and chestnut-bronze colour with a golden reverse which is prominent in the centre of the blooms. Card of commendation. Shown by Mr. H. Woolman.

CITRON.—A valuable single-flowered variety of the substantial round habit of Mensa, but a trifle smaller. The colour is a bright canary yellow, and the golden disc is exceptionally small. First-class certificate. Shown by Messrs. W. Wells and Co.

MRS. PHIL PAGE.—Although there does not appear to be any relationship, this novelty is a reddish counterpart of the golden bronze Mrs. Jack Pearson, which received award last year and already is a valued market variety. The novelty has the same broad stiff petals and compact form and is of bright reddish chestnut colour. It does well either disbudded or in spray form. First-class certificate. Shown by Mr. Philip Ladds.

SALMON PROFUSION.—This variety is of most uncommon colour, which may best be generally described as pinkish fawn, although we believe the official description is light salmon-pink. The flowers are of good size and possess plenty of substance. First-class certificate. Shown by Mr. W. Yandell.

SILVER QUEEN.—A most delightful flower and of unusually good form and large size for a hardy variety. The fully double blooms are made up of plenty of broad incurving florets of pale old rose colour with a silvery reverse. First-class certificate. Shown by Mr. H. Woolman.

WEMBLEY.—This is another splendid early-flowering variety for the open border. When first open the flowers have broad, stout, incurving florets, which with age become rolled and reflexed, making a perfectly formed Japanese chrysanthemum of good size. The colour is a rich ruby-crimson. First-class certificate. Shown by Mr. H. Woolman.

NEW FRUIT.

GRAPE COTE HOUSE SEEDLING.—Following an inspection of the vine at Gunnersbury House Gardens, Acton, the Committee confirmed the award to this valuable grape. It is a seedling derived from Black Hamburgh and Muscat of Alexandria. The influence of the former is seen in the compact, moderate-sized bunch of roundish berries, while the latter gives rich amber colour, firm flesh and Muscat flavour. The vine is growing in a house with Black Hamburgh, and requires very little fire heat, while the bunches keep in good condition for a long period. Award of merit. Shown by Mrs. Leopold Rothschild.

ORCHIDS.

LÆLIO-CATTLEYA VAR. MILO (C. Hardyana × L.-C. St. Gothard), from Messrs. Stuart Low and Co., Jarvisbrook, Sussex. A handsome hybrid with a couple of large flowers of a pleasing magenta rose colour, the wide labellum having the frontal area of ruby crimson, the throat veined with golden yellow.

BRASSO-CATTLEYA DIETRICHIANA LAMBEAU'S VARIETY (B.-C. Mrs. J. Leeman × C. Fabia), from Messrs. Stuart Low and Co. This richly coloured variety has for some time past been recognised as the best of its kind. The whole flower is of deep crimson-purple, the broadly developed labellum of darker tint, and with the margin prettily fringed. Award of merit.

GROUPS.

Among the groups of orchids Messrs. Sanders, St. Albans, and Messrs. Stuart Low and Co., Jarvisbrook, Sussex, were both awarded gold medals for exhibits of outstanding merit.

MICHAELMAS DAISIES.

Judging by my collection at home, September 23rd was a little early this late season for a full display of asters in all their glory. Notwithstanding this there was a very respectable gathering of the clans. Here and there there were unmistakable evidences of the buffeting the flowers had had; but, on the other hand, many looked "as fresh as a daisy." The two points which come vividly to my mind as I write these words and which impressed me more than anything else in connection with the display were the need of a first-class single white and the variation which something produces between the same variety when grown in different places and by different people. The good old chestnut that I have known from my youth up, "Look here what do you think I will shave you for nothing and give you a drink," depends upon emphasis and stops for its meaning. Why did Queen of Colwall appear to be a double in nearly every case where it was staged, except in Mr. H. J. Jones' group, where it was in what I should call its true form of a delightful big single, if I may judge by its behaviour with me? Mr. Jones likes to have two year old plants to cut from. He thinks he gets a better cut then than from either older ones or one year olds. Personally, I like the one year olds, but then the soil must not be too rich. He told me a tale to illustrate the difference that age or rich feeding can make. The late Mr. Wilks told him in a conversation before one of his groups that he did not care for Sam Banham and thought it was much over-rated. "Now that white, Mr. Jones, I do like," as he pointed to a back or top row variety. "Yes," said Mr. Jones, "that is Sam Banham." All this means that Michaelmas daisies depend on the way you treat them, like the meaning of the barber's sign depends on how you read it. Yes! there were "Whites to the left of them, whites to the right of them," and I think I saw them all—Perry with Perry's White, Wells with Wells' White, Ballard with Snowdrift, Queen Elizabeth and White Button, Jackman with Woking White, Wood with White Climax, and Jones with a seedling of his own. Queen Elizabeth has a split up centre, which to me is much what a split infinitive is to literary purists. Wells' White is too much of a cream in a growing mass and so on. At present I plump for Perry's White, but I am going to keep an eye on White Climax and Woking White. Few herbaceous exhibits were without some examples of Michaelmas daisies, thereby showing most unmistakably the growing popularity of these hardy stand-bys. Mr. H. J. Jones of Lewisham, Messrs. Cutbush and Son of Barnet, Mr. Ernest Ballard of Colwall, Messrs. Dickson and Robinson of Manchester and Mr. H. Hemsley of Crawley had the most important displays; but many good varieties were staged by Mr. Amos Perry, Messrs. Wallace and Co., Messrs. George Jackman and Son, Messrs. Bakers and others. Probably few noticed the little collection of named varieties of the Amellus group staged by Mr. Reuthe. King George was everywhere, so one was glad to see the number of varieties in the group brought before the public by ocular demonstration. I picked out Wienholtzii (pink), Imperator (rich purple), Stella (pale mauve) and the type which still takes some beating. My editorial instructions were to especially note new and uncommon kinds, hence the older stagers must be omitted. I only make one exception, and that is Lavender. Three novelties gained awards of merit. Personally, I should never have voted for Royal Blue. I do not like the form of its flowers, which are neither fish, flesh, fowl nor good red herring. If I am to have a double, let it be a double like Little Boy Blue. Maid of Athens is a deep rose-pink, deeper a little than Countess, which in turn is deeper than Ethel Ballard. Thora Perry is a dwarf variety with a pale lavender inflorescence of a corymbaceous type. The flowers are double and singularly flat-looking. It is a lady's flower, I think. Messrs. Dickson and Robinson and Mr. H. J. Jones had more novelties and uncommon varieties than any other firm. From various groups I made note of the following: Pink Pearl, small, rosy, curious shade; Violet, pretty pale mauve; Charm, pale pink, reminds me of Louvain; Glorious, large rose; Walkden's Pink, deep rose; Chivalry, small type, pale lavender; Cream Early, small type, creamy white, very effective; Pioneer, pink; Robinson, V.C., purple double; Cloudy Blue, grey—ought to change names with Grey Lady, which has too much pink in it to be a grey; Blue Gem, runs a race with Edith Goodwin for blueness; and Purple Emperor, rich purple.—JOSEPH JACOB.

NOVEL AND UNCOMMON VARIETIES OF MICHAELMAS DAISIES IN ALL SHADES OF BLUE AND PURPLE WERE TO BE FOUND ON THE STAND OF MR. H. J. JONES.

AUTUMN TREATMENT OF LAWNS

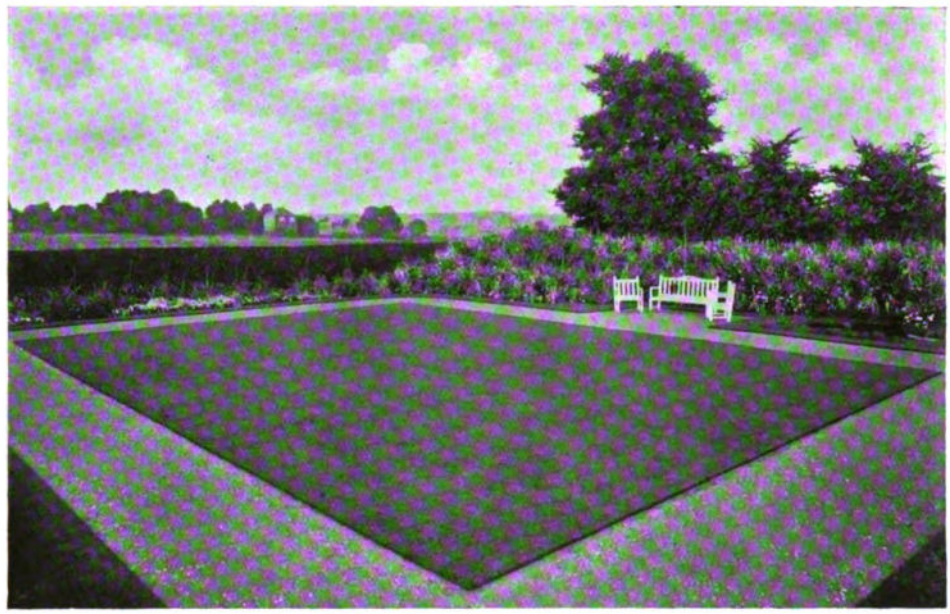
THEIR PREPARATION FOR THE WINTER

AUTUMN is an important period of the year for lawns. Their summer beauty is then on the wane and the time has arrived to build them up for next season's display. During September and October whatever seeding or re-turfing is necessary should be done so that full advantage may be obtained of the growing period which generally goes on at that time.

Lawns that are used for games ought to receive attention first. Tennis is probably the most popular sport of all, and immediately play has ceased the restoration of the turf must be commenced. Turf that has gone through a season of play must necessarily be in a weakly condition, and if it is allowed to go on unattended throughout the winter it will be weaker still in spring. Begin by re-turfing all worn-out places and in doing this it is of great importance that the turf used should be of equal quality to the turf which is growing on the court. It is rarely that turf imported from another district is suitable for the purpose. The game of tennis has reached such a high standard that it is of the utmost importance to have the whole area of the court of equal texture throughout. This is best obtained by using the turf from the ends or sides. The worn-out turf can be replaced in the vacated spaces, and if seeded and nourished will soon recover and be useful in two years' time for patching again.

After the re-turfing is completed the whole area should be gently raked or rather combed with a sharp-toothed iron rake. This will remove the surface compression which has been caused by continuous rolling during the season of play. It will also raise up any recumbent growths of grass which may be there and enable them to be cut off close with the lawn mower. Running grasses, such as the varieties of agrostis, are not wanted on a tennis court. Whatever weeding is necessary could be done during the progress of raking.

At this stage nourishment which will induce a hard, close, wearable growth of grass must be given. If the right food is applied, it will do good, and in the same way the wrong food will do harm. Probably more damage has been done to turf by indiscriminate feeding than any other agency. There is no universal manure for grasses. It is not the first time that I have insisted grasses are plants, and to get them in the best condition they must be treated as such. They give a result according to the cultivation they get. A common prescription for nourishing turf is soil. Sometimes farmyard manure, road scrapings or the dredgings from a stream or lake are incorporated with the soil. A dressing of this nature does not benefit the grass. Instead of doing so it creates conditions conducive to the growth of weeds, and harmful to the finer grasses. When it is spread over the lawn and afterwards rolled in it forms a scum, or crust, which prevents the grasses from obtaining healthy surface root growth, one of the most necessary essentials for their well-being. Not only does it do this, but it forms ideal conditions for the growth of most weeds which infest a lawn. Examine a plantain or a daisy and you will see how luxuriantly it spreads its leaves over the crusted surface, while underneath the layer its roots are spreading out freely in all directions. Then look at the grasses and they are generally found to be weakly specimens, with feeble root growth.



"THE SPRING'S REWARD OF AUTUMN'S LABOUR."

The best food for grasses is a preparation that will tend to keep the surface porous and give the nourishment which the plant requires. If the grasses are weakly, occasional light applications of chemical manure are more effective than a heavy dressing at wider intervals. The composition of this food must vary according to the nature of the soil in which the plants are growing. The practice of applying a preparation on soil of a different character to that on which it has given good results has done damage to many lawns. On very dry soils potash might predominate, while on moist ground phosphates could hold the pride of place. When clover is strongly in evidence, nitrogenous preparations are frequently used, but there is no nitrogenous compound that will permanently clear away clover. Where clovers are prevalent grass roots are generally weak, and if after an application of clover exterminator a system of cultivation is adopted which will increase root growth, a good result will be obtained.

Croquet lawns are not subjected to the same severe wear as tennis courts and are more easily put right after the season of play has ceased. The turf should be of even texture throughout and accurately level. Any inequalities that may exist must first be corrected, mounds need to be reduced and hollows raised up. A good method is to get a straight-edge and go over the lawn in sections, correcting each fault as it is reached. It is remarkable how settlements will occur on established lawns without any noticeable cause, and therefore an annual overhaul in this way is very necessary. When this is done chemical manure as advised for tennis courts should be applied evenly over the surface. The rate at which the chemical manure should be applied on lawns must vary with the condition of the turf, but 1cwt. to 300 or 400 square yards is generally sufficient for an annual dressing. When the turf is thin, grass seed must be sown. This can be done by making numerous shallow holes and then sowing the seed rather thickly after it has been mixed with an equal proportion of fine sand.

The same instructions hold good for lawns in general. This is the time to put anything right which may be wrong, so that with the advent of spring the lawn mower can be put to work on turf as nearly perfect as it is possible to be. But in writing this I do not mean to infer that the lawn mower must be locked up in its house from now until the cuckoo comes. It may be, and in fact there frequently is, a grass growing period during late autumn and winter; this growth must be mown, but it is necessary to select dry periods for such work. This generally occurs after midday, and therefore afternoons ought to be selected for using the lawn mower. The roller may safely be locked up until next season. It does harm if used during winter, and should have a rest until required for the croquet or tennis lawn just before play commences.

JAMES MACDONALD.

CORRESPONDENCE

FATS-HEDERA LIZEI.

SIR,—As I have seen no mention in the columns of THE GARDEN of the arrival of the long wished for hybrid between the common large-leaved Irish ivy and the useful evergreen shrub aralia or Fatsia Sieboldii, I should like to draw the attention of your readers to it. In the last number of the *Revue Horticole* there is an illustration of its vigorous growth and excellence as a hardy evergreen tree. Its name is descriptive, but so ill sounding that I wish a better one could be found. Fats-hedera Lizei is a name to frighten the ignorant, and leaves much to be desired, even although it be botanically correct. How useful this plant will be as a seaside evergreen I need hardly say. We shall look forward to the day when the raisers announce its distribution.—EDWARD H. WOODALL, *Scarborough.*

CAMPANULA CÆSPITOSA.

SIR,—A striking instance of the difficulty mentioned by Dr. P. G. Hendley on page 637 may be found in the name Campanula cæspitosa. Farrer gave a description of what he considered had first claim to the name in "The English Rock Garden," and previously (I believe) in THE GARDEN of September, 1913, though in his earlier works he made it synonymous with pusilla. He gives no alternative name to it, and as the cæspitosa of catalogues is pretty certain to be a variant of pusilla, it is impossible to know how or where to get the plant Farrer describes. Can anyone shed light on this subject?—L. J. ROGERS, *Oxford.*

KNOT GARDENS.

SIR,—In the article on Knot Gardens in your issue of September 6th, the writer speculates on "what exactly were the raisins, and likewise the fea-berries."

There can be no doubt that feaberries—whether spelled fe-berries, faberries, feabes, or in other ways—were gooseberries.

They appear as gooseberries in Gerald's Herbal (1597), Cotgrave (1611), Ray (1674, "Feabes, Feaberries, Thebes in Norfolk") and are so defined in Cole's Dictionary (1713), Bailey's (1755), Grieb's German-English Dictionary (1847 = Stachelbeeren) and G. W. Johnson's Dictionary of Modern Gardening (1846).

The Oxford ("Murray's") English Dictionary agrees and gives the derivation as probably from M. E. Theve, a prickly shrub.

Thus it is clear that the "frets" in knot gardens were not necessarily neat and trim little borders like box, which is omitted from the list in the "Country House-wives Garden," as your article shows, but fairly robust hedge plants like "privits," "thornes" and "gooseberries."

Why, then, should not the raisins be grape vines, probably espalier trained? The old writers used the term "raisin" to indicate the vine or "raisin tree": but it is possible that the Ribes is meant—see Turner (1548), "Names of Herbes": "Rhibes is called in some parts of England the Raisin Tree."

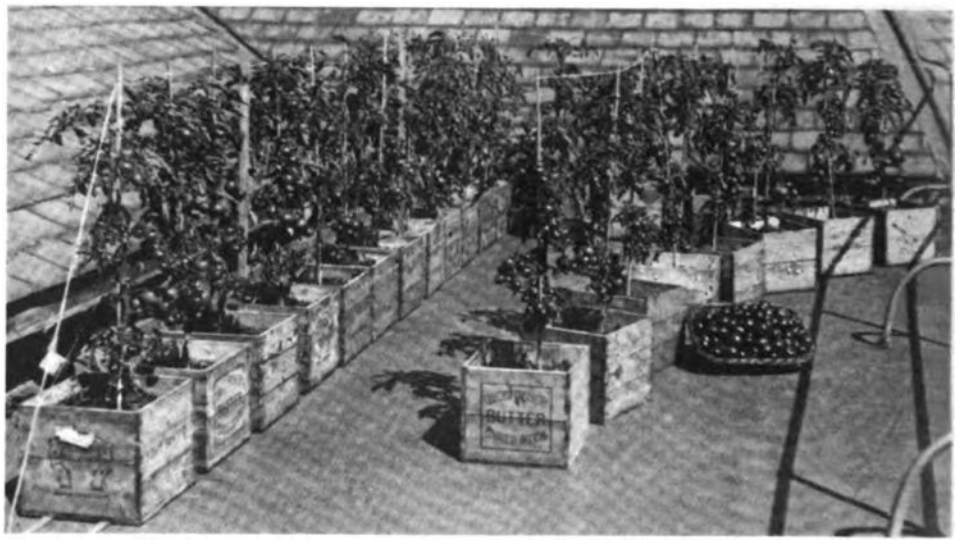
There was something practical in planting gooseberries and vines as borders of a pleasaunce: I remember many years ago advising a farmer to plant gooseberry instead of thorn hedges between some of his fields.—J. H. H., *Bradford.*

SAXIFRAGA BURNATI.

SIR,—On page 622, under the heading "Saxifraga cæsia," I carelessly and stupidly wrote that S. Burnati=S. cæsia × Aizoon instead of S. cochlearis × Aizoon. Particularly, as I misquoted the word cochlearis in Irving and Malby's excellent book on Saxifrages, do I regret that only to-day (September 17th) did I hear from a friend of the error I had fallen into.—H. S. T.

TOMATO CULTURE ON A ROOF.

SIR,—I have been asked to forward this illustration to you in the hope that it may prove of interest to the many readers of THE GARDEN. This is a very fine crop of tomatoes grown by an employee on a roof in the centre of the city of Oxford, also showing a basket of picked ripe fruit in fine condition. These were grown on the premises of Messrs. Grunley Hughes and Co.—F. J. FRENCH, *Oxford.*



AN INGENIOUS METHOD OF GROWING TOMATOES WHICH, APPARENTLY, MEETS WITH GREAT SUCCESS.

TREES AND SHRUBS DYING.

SIR,—During the last few weeks I have noticed that quite a number of trees and shrubs have suddenly collapsed and died in the course of a few days. A mountain ash was on a Tuesday in full vigour, healthy leaves and plenty of fruit, while on Saturday it presented a pitiful sight. Another plant, Genista virgata, a large specimen, also died within a few days. Other examples include thorns, beech and philadelphus. It has been stated that the present season is a good one for trees and shrubs, and no doubt it is judging from the growth made, but why some of them should die is remarkable. Perhaps other readers can supply the reason, and also state if they have lost any plants this summer. Certainly, drought has not caused it in this district, for August was an exceptionally wet month, while July and September were characterised by the large number of wet days.—T. W. B., *Chepstow, Mon.*

A FURTHER LETTER ON MAGENTA BORDERS.

SIR,—It is very refreshing to read the letters about a magenta border, and I venture to add a few notes. I have always had a sneaking fondness for magenta flowers, partly because they are old-fashioned and also many grow wild. They are not easy to blend, but certain combinations can be observed among wild flowers which help in the garden. When in Yorkshire at Whitsuntide I was greatly struck with the beauty of spikes of purple orchis standing among groups of trollius, and much the same colouring occurs when the orchis grows among cowslips in a meadow. They also look very telling growing in thin woodland among bluebells, and honesty is quite effective standing in a carpet of bluebells or forget-me-nots. Erica carnea also edges a border nicely, and is doubly welcome because it blooms so early; later its foliage contrasts well with that of nepeta or lavender. Primula Juliæ and a hybrid named Wanda bloom very early. Wanda will grow and flourish in the border, but I have only grown Juliæ in the rock garden. Many flowers have been mentioned, especially the grey-leaved agrostemma, always known to me as Rose Campion. I never knew anyone dislike it and am constantly being asked for young plants. It makes a charming association here with Campanula Rapunculus, a biennial which is like a glorified harebell, but much taller and pinkish mauve. It is often described as a weed, and if allowed will seed all over the place, but it is so graceful and airy that I dearly love it. Geranium armenium makes a handsome plant of an intense colour, but I once saw it flowering against an ordinary scarlet bedding geranium, and it was enough to make one hate magenta for ever (or scarlet). Erodium Manescavi is a pretty magenta flower and Geranium sanguineum is beautiful by itself, but terrible if not carefully used. Gaps can be filled with the annual candytuft, which looks quite suitable with old-fashioned flowers, and has been improved enormously. One can obtain the same colour, too, in the annual linaria. Fuchsias flower beautifully in the autumn, and carry on the various crimson tones, and dahlias can be found to blend as well as chrysanthemums.—E. BUXTON, *Burton-on-Trent.*

OFFER OF SEEDS.

SIR,—Your paper seems very anxious to render service to all garden lovers—I am wondering whether you would be willing to let the gardening public know, that to anyone sending me a stamped and directed envelope, I would gladly send a few seeds of Magnolia tripetala, M. salicifolia, Rosa macrophylla, R. pendulina, Euonymus latifolius.

It seems such a pity to throw away, at the end of the year, things which probably many would appreciate. The magnolia seeds very soon lose their power of germinating.—A. C. BARTHOLOMEW, 75, *Tilehurst Road, Reading.*

HARVESTING TUBERS FROM THE FLOWER GARDEN.

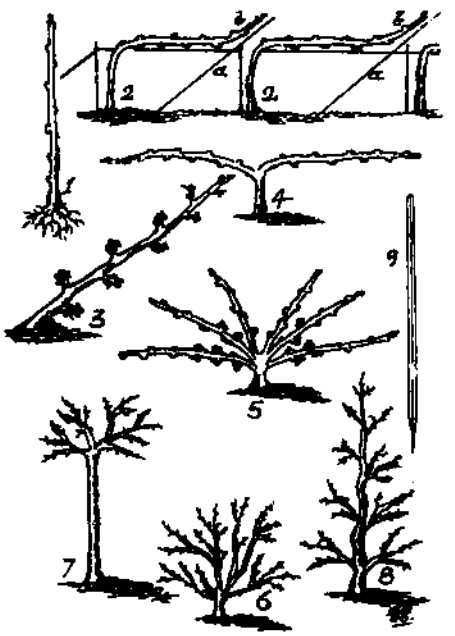
THE tubers of plants that have been well grown in the flower-beds should be finer now than they were when first planted out, and every care should be taken to keep them safely and quite sound during the winter months. The first of importance to be ready for lifting are the tubers of dahlias. Some of the cactus and small-flowered sections are very beautiful and well worth preservation. After the flowering stage has passed the tops should be cut off to within a foot or so from the base directly the leaves begin to fade and before frosts seriously damage them. Then carefully lift and place the roots in a dry, cool shed, leaving them there till the soil is dry and can be removed without injury to the tubers. Any dry storeroom will answer the purpose, or a dry cellar, but not a high loft where frost can enter from below as well as above. Dry sand is suitable for packing round the tubers, burying the crowns several inches also. Fasten name labels to stalks securely as well as to the tubers and place dry straw on all to keep out frost if it is severe. Gladioli corms should also be lifted with stems and leaves attached and be laid on a dry floor to finish ripening before storing the corms in paper bags or boxes in dust-dry leaf-soil or coconut fibre. Begonia tubers should be similarly treated in a greenhouse frame and finally stored in leaf-soil or coconut fibre in boxes in a dry part of the greenhouse. Do not forcibly remove the stems from the tubers, let them mature first.

GUARDING AGAINST FUNGUS IN THE AUTUMN.

The present year has been productive of fungus in a very bad form on various kinds of plants, fruit trees and vegetables. We should not wait till another year without taking measures to protect our garden crops from its ravages next year, as the spores live in the soil and on plants and thrive amazingly again directly suitable conditions obtain. Lime is a good preventive, and not only kills fungus in the soil, but improves the latter considerably. Where possible, mix lime with the soil and freely with garden refuse in cases where the latter cannot conveniently be destroyed by fire. The ashes of such refuse should be stored in a dry state in a dry, cool shed in readiness for use in the garden next year. Sulphur is also a good agent and, properly mixed to the consistency of paint, should be in due course painted on vine rods—taking care to keep it from touching the buds or eyes—and judiciously sprinkled in a dry state on the soil of the borders and under stages, even on the hot-water pipes in vineries and peach-houses, so that fumes may be given off when the pipes are gently heated to exclude frost. But the sulphur must not be applied to the pipes in plant-houses. Chrysanthemum stems and leaves should be burned forthwith, as rust and mildew often infest these. Both in the garden and glass structures absolute cleanliness should rule, then the risk from infection next year will be reduced to a minimum.

FORMS OF FRUIT TREES.

The season of fruit-tree planting has come again, and cultivators will be busy, first selecting varieties of the various kinds and the type of tree.



It is a mistake to plant many standards, pyramids or similar forms in small gardens. Cordons, single and double, and those in bush form are very serviceable for small gardens and also for large ones. More cordons can be grown in small space than large bushes, of course, and so the amateur is able to grow a really good selection of varieties of apples and pears. I am only making reference to forms of fruit trees now, in due course I hope to illustrate the work of planting. No. 1, one year old maiden; Nos. 2,2, horizontal cordons; *a*, *a*, supports for extending trees where convenient, shown at *b*, *b*,; No. 3, oblique-trained cordon; No. 4, double horizontal cordon; No. 5, fan-trained dwarf; No. 6, bush; No. 7, standard; No. 8, pyramid; No. 9, the necessary stakes to prepare.

THE WALLFLOWER.

Few lovers of gardens can do without the wallflower. In both the large and the small garden the plants look charming and their fragrance is delightful when well grown. The latter is a very important point, as, since these plants will grow in almost any kind of soil and in many positions, they are allowed to grow as best they can by some cultivators. But, like other plants, they return a grand reward for good cultivation. A wallflower plant will grow in poor soil or in a gravel path or between the courses of bricks in a wall, but the resultant flowers are small in contrast with those on plants growing in a fairly rich medium. The soil should be made as rich as that usually prepared for zonal pelargoniums, but while it is in a rather dry condition such soil should be firmed a little if light and sandy. Lift the plants with the aid of a hand trowel or fork, do not forcibly pull them up, mutilating the roots, as is often done. Plant with a trowel or fork and make firm the soil round the roots. Do not plant closer than 9ins. from plant to plant. Where it is possible to do the final planting in October the results are generally very good.

CYCLAMENS: SEEDLINGS AND SEEDS.

The seeds of these plants do not, as a rule, germinate quickly, and where there is a suspicion that more seedlings should result from, say, an August sowing, it is best to be patient and wait a month or so before giving up hope. Another sowing of seeds should be made now. The cyclamen thrives in a compost in which sweet, half-rotted leaf-soil is incorporated. Fibrous loam, which has been cut and heaped about three months, should form the prinicpal ingredient; 2 parts of this, 1 part of leaf-soil and a generous sprinkling of coarse sand. These form an ideal compost. Pans or flower-pots should be used, not boxes, as the latter are too dry and a constant moisture is beneficial. A substantial drainage should be provided and the compost placed in, gently pressed, and left with the surface ½in. from the top of the rim to allow the resultant seedlings room to grow in under the covering square of glass. Dibble in the seeds 1in. apart and not more than ½in. deep. In addition to the square of glass, place a sheet of brown paper on the pan to exclude sunshine. Later, when the seedlings appear, the paper must be removed, but not the glass. In January it will be time to tilt the glass, and in February to remove it entirely, when preparations should be made to pot the young cyclamens singly, also those resultant from the August sowing. GEORGE GARNER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

General Work.—At this season it is advisable to keep the kitchen garden as clean and tidy as possible, and directly such plants as peas and beans have finished they ought to be pulled up and burnt. All decaying vegetable matter should be collected and buried. On wet days examine potato tubers in store, and those selected for seed purposes may be set out in trays or boxes. In some districts the disease is rather prevalent, so it is essential that the bulk of tubers must be looked over at frequent intervals.

Parsnips.—These are dug up as required and the flavour is improved after a little frost. If, later on, we experience very severe weather, rough litter or bracken should be placed over the crop, while a quantity of roots ought to be lifted and stored in ashes or sand.

THE HARDY FRUIT GARDEN.

Grease-banding.—Few private gardeners follow the practice of grease-banding, but no doubt it is very efficacious in dealing with the female moths, which ascend the trees at this period of the year. Both parchment bands and "moth grip" or grease can be bought ready prepared. The bands are fixed around the trunk of the tree from 2ft. to 5ft. from the ground. First remove any loose or rough bark where the band will be fixed to prevent any moths creeping up between the band and the tree. Tie the bands both top and bottom with string, and then apply the grease or "moth grip" with a stiff brush. About 3ins. of grease will be ample, and care should be taken to keep it off the trees. Where stakes are used, it will be necessary to give each a band. The bands will need attention every few weeks, and the dead moths collected and burnt, otherwise they will dry up and eventually form a bridge for other insects. Apply a little more grease when necessary.

Raspberries, when planted in lines, should be from 5ft. to 6ft. apart, and if in clumps then 4ft. of space ought to be allowed in each direction. Although it is often stated that raspberries are shallow-rooting, they thrive better where the ground has been deeply dug or trenched. Select plants with plenty of fibrous roots, even if the canes are small; it will be found generally that strong large canes rarely possess many healthy fibrous roots. There are now several fine raspberries in commerce, but Red Antwerp is still among the first half-dozen.

THE FLOWER GARDEN.

Specimen Plants.—Plants in tubs or large pots that have been used as specimens in the flower garden or along walks and drives should be placed under cover before they are likely to be ruined by frosts. If arranged in a frost-proof structure and afforded water in moderation they will be useful, healthy plants next season.

Summer Bedding.—The wet and dull weather during the last few weeks has spoilt many of the occupants of the flower beds. Directly it is possible, clear the beds and put out such plants as wallflowers, polyanthus, myosotis, etc.; while if bulbs are used they ought also to be planted without delay.

Pits and Frames.—Rooted cuttings in pits and frames will need careful watering to prevent any damping off. Admit plenty of air whenever possible, to encourage a strong growth, and at intervals pick off all decayed leaves and flowers.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Jerusalem Artichokes.—The stems at this period may be cut over to about half their height; this will allow of the plants being more easily handled when the tubers are being dug up for use.

Salsafy.—This is another vegetable which, like the parsnip, may be left in the ground and dug up as required or stored in the shed among sand or fine soil.

Vacant Ground.—Sections which have been cleared of peas or root crops should be manured, where it has been decided to do so, and the ground dug or trenched, as may be found necessary.

THE FLOWER GARDEN.

Chrysanthemums.—It is possible even before this date to get large numbers of rooted shoots from around the base of plants growing in the borders. These shoots or young plants should be carefully forked up and severed from the parent plants. They should be set in boxes of medium fine potting soil, then watered and the boxes placed in a frame. Where a scarcity of any variety exists, it is wise to take these partly rooted shoots when procurable.

Scrophularia nodosa variegata.—This somewhat attractive plant, although old fashioned, is not so very often seen in gardens. Nor, perhaps, is this to be wondered at, when one looks through an up-to-date catalogue of hardy plants and fails to find such a name mentioned. The variegated figwort, for such is its common name, adds beauty to the borders for many months by its tall and stately stems so well furnished with variegated leaves. It is quite easily propagated by cuttings, which can be had in quantity from the sides of the stems of well grown plants. The cuttings should be secured now and dibbled into sandy soil in a cold frame and treated like viola cuttings.

Violas.—The cuttings are found in quantity as young growths about the centre of established plants. Oft-times it is possible, by giving a gentle pull when taking the cuttings, to obtain several with little roots attached. These should be dibbled into a frame straight away, and they need little or no preparation. To prepare the other shoots, cut immediately below a joint and remove a few of the lower leaves, make the finished cutting 3ins. long and insert in firm sandy soil in boxes or in a cold frame. When the cuttings are put in, give them a watering, using a rose on the can for the purpose. The frame should be kept closed and the cuttings shaded from bright sunshine for a week or two, afterwards gradually admit air for a short time each day, giving an abundance later on, on all favourable occasions, so that the plants are kept as hardy as possible.

THE HARDY FRUIT GARDEN.

Mulching.—There is no doubt that fruit trees send out young and fresh roots in autumn, and at the same time the leaves exhibit that choice and charming colouring which gladdens the heart of humble man. Here, then, is an opportunity to add something which will further sustain and build up fruitful and healthy trees. A mulch of old farmyard manure spread around the base and near the stem of each tree will provide material into which roots appearing near the surface can grow and feed upon. Where farmyard manure can be easily obtained all kinds of fruit trees and bushes will benefit by a mulching at this period of the year.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Oxalis floribunda is now flowering for the second time after being rested for a while and again started into growth. This plant is worthy of more general cultivation, as it is so useful for the unheated greenhouse. It only requires the shelter of a cold frame, from which it may be removed when it comes into flower. There is also a white-flowered variety. Both are very useful for filling hanging baskets for the greenhouse.

Oxalis purpurata, with very large, showy flowers, is now in bloom, and succeeds under the same conditions as O. floribunda. Both species are more or less hardy in the South at the bottom of warm south walls, and O. purpurata is now very fine in such a position. Dry roots of both species can generally be purchased during the autumn.

Cinerarias, Cyclamens and Chinese Primulas that have been growing in cold frames during the summer should now be removed to light, airy houses, where they can be given plenty of air and be kept well up to the roof glass. Many other plants that have been stood outdoors or in cold frames will soon require to be removed indoors, but as a rule many of them are better kept outdoors as long as possible, and temporary shelters can often be arranged where they can be protected with canvas blinds when frost threatens.

Irises.—There is quite a number of small bulbous and tuberous-rooted irises that are very suitable for the small unheated greenhouse. Most of them are hardy, but grown in pots or pans they are independent of weather conditions, and can be enjoyed in comfort indoors. They all grow quite well in any good potting compost. Some of the smaller species, such as I. Danfordiæ, Vartani, reticulata and its varieties are very beautiful when grown in small pans. I. alata, Histrio, persica, Bakeriana, orchioides, sindjarensis and Rosenbachiana are all suitable for this purpose. After being potted they only require the shelter of a cold frame until they come into flower, when they may be removed to the greenhouse or into the dwelling-house if so desired. I. susiana and iberica belong to a different section of the genus and are very beautiful when grown in pots. There are other species belonging to the same section, such as I. atropurpurea, Gatesi, Lortetii and paradoxa. They all belong to the Oncocyclus and Regelia groups, and are by no means easy of cultivation; but there is a set of hybrids between these two groups that has proved more amenable to cultivation, and although they grow outdoors on a warm border, they are well worth growing in pots for the cool greenhouse. Their flowers, which are veined on white, purple, violet and brown grounds, are very striking and beautiful, and always attract attention. They grow quite well in any good potting compost, using well drained pots. Three or four strong rhizomes may be placed in a 6in. pot. As the rhizomes run along the surface of the ground, they should be barely covered with soil when they are potted. After potting they should be stood in a cold frame in a position fully exposed to the sun. Very little water should be given until they have made a quantity of roots and have commenced to grow. They may remain in the frames, giving them plenty of air on every favourable occasion—until they commence to flower, when they may be removed to a cool greenhouse. The following are a few that are distinct and fairly cheap: Charon, Eucharis, Eva Hecate, Hera, Hesperia, Irene, Ismene, Jocaste, Mars, Medusa and Urania. J. COUTTS.
Royal Botanic Gardens, Kew.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Preserving Flower Petals in Natural Colours (J. McG.).—Use 1 teaspoonful of gum arabic dissolved in 1 pint of boiling water. When the mixture is cold, dip in the flowers, lay them on a sheet of white blotting paper to dry. When quite dry, press in between sheets of white blotting paper. There is also a solution of wax on the market used for preserving natural flowers, but we are unable to say where it can be procured—probably from chemists. The gum arabic should also be obtained from a chemist.

Rose Queries (J. McG.).—Certain varieties of roses are not pruned in the usual way—*i.e.*, like the pruning of hybrid teas and hybrid perpetuals—but have the tips of the shoots cut off; this is done simply to remove the unripened portions only. The Bourbon section are mostly autumn-flowering; Zéphirine Drouhin, autumn-flowering; Purity, autumn-flowering; Coupe d'Hébé, we do not recognise this variety. Emily Gray is suitable for a wall. The Wichuraiana section is suitable for most walls, but not in very hot positions. For a high wall, Minnehaha, L'Ideal, Milky Way, Mme. Isaac Pereire, Mrs. F. W. Flight, Félicité et Perpétue, Tausendschön, W. Allen Richardson, Aimée Vibert, Claire Jacquier, Alister Stella Gray, Persian Yellow, Excelsa and Dundee Rambler. Hugh Dickson should be allowed to grow freely, thinning out to prevent overcrowding, and cutting off unripe tips to ensure quantity of flowers. George Dickson: procure as many secondary or late shoots on the plants as possible. H. E. Richardson: treat this the same as Hugh Dickson. Juliet: treat this similarly to the Austrian briars.

TREES AND SHRUBS.

Flowering Shrubs (T. H. H.).—The following are twelve very serviceable shrubs for your purpose: Andromeda floribunda, deutzia, forsythia, lilac, ribes, philadelphus, rhododendron, snowberry, arbutus, Buddleia globosa, Escallonia macrantha and laurustinus.

FRUIT GARDEN.

About Fruit Trees (Lady G.).—We are inclined to agree that "weather" is by no means the sole cause of the fruit trees failing to thrive and crop. In the first place, the fact that all sweet cherries are more or less self-sterile may be the reason that the flowers fail to "set" fruit, but in your case, apparently, it is not so much that the flowers do not develop into fruits as that "little or no blossom is borne by the trees." Self-sterility or fertility can in no way influence the formation of blossom buds or the amount of blossom produced—only can it affect the "setting" of the flowers that are produced. In the circumstances we think that the trouble lies elsewhere, and would suggest that in all probability the border is at fault. If the soil is at all cold and wet, and badly drained, or if lime is lacking, the trees will make coarse, rank growth at the expense of fruit buds. We think it would be well to make quite sure that the drainage is all right by taking out the old soil in the border and relaying the tile drains. When the soil is returned, add a quantity of broken lime rubble, and if at the same time wood ashes and basic slag can be added, so much the better, the latter at the rate of 4oz. or 5oz. to the square yard. This would undoubtedly do good, the best time to attend to the work being just as the leaves are falling in late autumn. If the roots were not pruned (as we note were the pears) last year, then they should be attended to at the same time. We think attention to these few points would do much to encourage fruitfulness. With regard to the pollination of the blossoms, if there are several varieties in the garden there will be little to worry about in this direction. However, if you would let us have a list of the kinds grown, we could advise on this point more definitely. Sterility occurs among apples, pears and plums just as with cherries, but here again, if several kinds are grown, effective cross-pollination should take place in any year. We think that the addition of lime rubble to all the fruit borders would be distinctly beneficial, and if there is a possibility of the drainage being at fault it should be attended to without delay. Cutting hard back as suggested for the plums is quite likely to do more harm than good, and it would be far better to carry out the ordinary pruning routine regularly and carefully. Of course, the cherries and pears—and plums too—should be summer pruned in addition to the winter work. No doubt the root pruning advised for the pears that are growing very strongly will do much good, though the good effects may not be immediately apparent. Nevertheless, if the border is at fault, root pruning alone will not render the trees fruitful. The treatment advised for the cherries would suit pears admirably. At sixteen years old, if properly pruned and cared for, the trees should be in their prime. Of course, the foot of a south wall is a very dry spot and frequent watering of the border during dry spells would be a great help, though it might not be needed so much in a season such as this. We have examined the apple spur and shoot sent, and both are in rather a bad way. The young shoot is covered with the apple mildew, a fungus disease very prevalent this year. Spraying with Bordeaux mixture in June and July is recommended as a control of this trouble, but we should prefer to rely upon the cutting out of every shoot coated with the white powdery mildew immediately it is noticed in early summer. Make quite sure that all such diseased wood is cut out when pruning this winter or a very bad attack next summer will certainly follow. The old spur sent is covered with moss and lichen, a sign that a good winter wash is long overdue. There is also a little scab present. Any of the proprietary winter washes might be used during the dormant season, or the simple home-made caustic soda wash will be effective. Two pounds of caustic soda dissolved in 10 gallons of water is the recipe. The Bordeaux sprayings in June will help control the scab, which appears to be slight. It may be a job to get trees so diseased and with spurs so aged back into good fruiting, and we would suggest that it might be best to grub them up and plant new ones. The peaches and nectarines are also in a very poor condition. They are very badly attacked by the silver-leaf fungus, for which there is no known remedy, and are also covered with red spider, a sign that their cultural management has not been all it should be. It would be best to grub these and replace them, as the silver-leaf cannot be got rid of and the trees are so poorly they would probably not recover in any case.

KITCHEN GARDEN.

Celery Diseased (J. M.).—The celery sent for inspection has been very badly attacked with the celery fly, which attacks in mild seasons may continue into December. The symptoms are in every way characteristic, the leaves assuming that brown and shrivelled-up appearance, becoming ultimately utterly valueless to the plant, while the stems cannot fill out properly. Where possible, it is wise to avoid growing successive crops of celery on the same ground. When only a few leaves in a bed are noticed, these should be pulled off and burned. A mixture of 3 parts soot and 1 part lime should be dusted on the leaves from April onwards. Paraffin emulsion is a good deterrent spray when the plants are in the seedling stages. Applications of nitrate of soda mixed with a little agricultural salt will effect a rapid leaf-growth, which is often desirable where there is a bad attack. Nicotine spray is also useful. All infected plants when dry should be collected and burned, to prevent further spread.

Tomato Plants Diseased (D. M. G.).—The leaves sent for examination are badly mildewed with the fungus so prevalent this season on account of the low temperatures, excessive moisture and lack of sunshine. Cut off and burn the leaves most damaged. If the disease occurs again next year, spray them with the Bordeaux mixture directly the mildew is observed under the leaves, as it is not wise to spray the fruits. Free ventilation is essential and each plant should have room in which to develop, the plants being 2ft. apart.

Names of Plants.—(T. A. D.).—1, Oxalis corniculata purpurea; 2, Sedum reflexum; 3, S. acris; 4, S. anglicum; 5, S. album var. brevifolium; 6, S. spurium; 7, S. rupestris; 8, S. Telephium; 9, Omphalodes verna. —— (S. H. B.). — Dimorphanthus mandschurica.

Wisley Trials, July 23rd, 1924.—THE following awards have been made to sweet peas by the Council of the Royal Horticultural Society after trial at Wisley:

AWARDS OF MERIT.

Flowers White.—Joan Ryder, sent by Messrs. Ryder; King White, sent by Messrs. J. K. King; Mascott's White and Edna May Improved, sent by Messrs. Ireland and Hitchcock; Constance Hinton, sent by Messrs. A. Dickson, Messrs. Dobbie and Messrs. W. J. Unwin.

Flowers Cream.—Cream Constance Hinton, sent by Dr. H. T. Hinton; Matchless, sent by Messrs. Dobbie and Messrs. Ireland and Hitchcock; Majestic Cream, sent by Messrs. W. J. Unwin; Hawlmark Cream, sent by Messrs. A. Dickson; Paradise Ivory, sent by Messrs. Kelway.

Flowers Crimson.—Charity, sent by Messrs. Ireland and Hitchcock. Other unnamed varieties very much like Charity were sent by Messrs. Barr, Messrs. R. Veitch, Messrs. J. Stevenson, Messrs. W. J. Unwin and Messrs. J. K. King. Crimson, Unwin's, sent by Messrs. W. J. Unwin; Crimson King, sent by Messrs. Morse, Messrs. Dobbie and Messrs. Webb; Maud Holmes, sent by Messrs. Barr; Sunproof Crimson, sent by Messrs. Dobbie and Messrs. Kelway.

Flowers Maroon.—Warrior, sent by Messrs. Dobbie. Other unnamed varieties very similar were sent by Messrs. W. J. Unwin, Messrs. A. Dickson, Messrs. W. H. Simpson, Messrs. J. K. King, Messrs. Webb, and Messrs. Ireland and Hitchcock. Nubian, sent by Messrs. Kelway; Maroon King, sent by Messrs. F. C. Woodcock.

CATALOGUES RECEIVED.

Messrs. Wm. Power and Co., 25 and 26, King Street, Waterford.—Bulbs.

Messrs. Robert Veitch and Son, Exeter.—Roses, Fruit Trees and Bulbs.

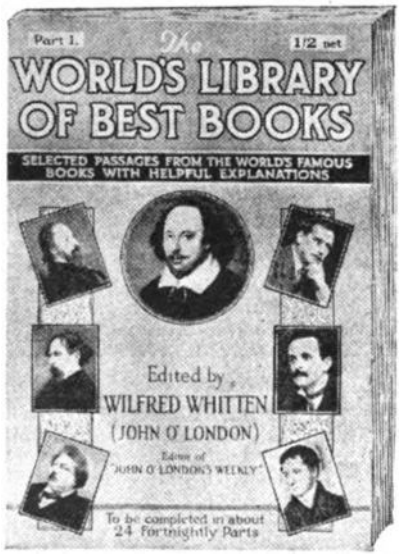
The WORLD'S LIBRARY OF BEST BOOKS

SELECTED PASSAGES FROM THE WORLD'S FAMOUS BOOKS WITH HELPFUL EXPLANATIONS



Edited by

WILFRED WHITTEN

THE purpose of this work is to give representative and extended selections from the World's Best Books. Each of these selections will be preceded by a clear, concise, and helpful introduction. In this way the Editor hopes that he will adequately convey to the reader's mind something of the *content*, the quality, the style and the significance of the world's best books.

SOMETHING DIFFERENT

This work goes far beyond a simple collection of beautiful or striking passages from favourite authors. Every selection from an individual book will be of sufficient length to enable the general reader, who lacks both time and opportunity for special study, *to appreciate the gist of a particular book and the peculiar qualities that have given it fame.*

"Infinite riches in a little room."

PART I.
H. G. Wells' "Character of Napoleon."
Shakespeare's "Antony and Cleopatra."
J. M. Barrie's "What Every Woman Knows."
Lamb's "Essays of Elia."
Tennyson's "In Memoriam."
Dickens' "Pickwick Papers."
Legend of the Golden Fleece.
Dumas' "The Count of Monte Cristo."

PART II.
Rudyard Kipling's "Barrack-Room Ballads."
Carlyle's "French Revolution."
Byron's "Childe Harold."
Thackeray's "Vanity Fair."
Cervantes' "Don Quixote."
Ruskin's "Modern Painters."
Thomas Hardy's "Return of the Native."

PART III.
R. L. Stevenson's "Master of Ballantrae."
Milton's "Paradise Lost."
Macaulay's "History of England."
Anatole France's "Penguin Island."
Byron's "Don Juan."
Ibsen's "Doll's House."
"The Arabian Nights." "The Third Calender's Story."

PART IV.
Victor Hugo's "Notre Dame."
Joseph Conrad's "Tales of Unrest."
Shakespeare's "Hamlet."
Robert Burns' Poems.
Maeterlinck's "Life of the Bee."
Gibbon's "Decline and Fall of the Roman Empire."
Goldsmith's "Vicar of Wakefield."

PART V.
Goethe's "Faust."
Froude's "Murder of Thomas à Becket."
Shelley's Shorter Poems.
Arnold Bennett's "The Old Wives' Tale."
Plutarch's "Lives."
Fitzgerald's "Omar Khayyam."
Edgar Allan Poe's "Mystery of the Rue Morgue."

PART VI.
H. G. Wells' "Tono-Bungay."
Dante's "Inferno."
Scott's "Red Gauntlet."
Meredith's "Richard Feverel."
Conan Doyle's "A Straggler of '15."
Sheridan's "School for Scandal."
Morley's "Gladstone."

(THE ABOVE CONTENTS ARE PROVISIONAL.)

This Unique Work will contain Hundreds of Beautiful Illustrations — A Great Many of Them in Colours.

1/2 PART 1 NOW ON SALE EVERYWHERE 1/2

MAKE SURE OF YOUR PARTS BY ORDERING IMMEDIATELY.

THE GARDEN
ORCHARD GARDEN WOODLAND

Vol. LXXXVIII.—No. 2760 Saturday, October 11th, 1924 Price THREEPENCE

The Kelway Colour Border

The formation of actual scenes of beauty with living subjects abounding in interest individually would seem to be a pleasant and worthy amusement, and one as full of dignity as the portrayal of such scenes on paper or canvas.
The late Dean Hole truthfully wrote in *Our Gardens :* "There has been no introduction which has had such happy and universal influence in extending and increasing the enjoyment of a garden as the HERBACEOUS BORDER." One of the first remarks of one's hostess in the country nowadays is, "Would you care to see my new Herbaceous Border ?"—or "my new KELWAY Border ?"
Send dimensions of space to be filled, and the effect required, stating aspect and soil, and asking any questions.

WRITE NOW to the inventors of Colour Borders :

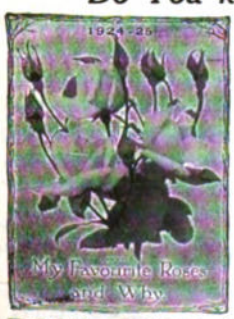
BARR & SONS, 11, 12 & 13, KING STREET, COVENT GARDEN, LONDON, W.C.2.

You will, I hope, forgive my arresting your attention. The question itself is really one of moment to you.

Do You know ? ***this Booklet ?***



If you know it, there is no question at all about it; you send for your copy every year and wouldn't settle your new list without it.

"MY FAVOURITE ROSES AND WHY" is a text book to give any beginner confidence, but it aims to be a YEAR BOOK and a ROSE ANNUAL that will keep an expert up to date.

Of course it is a Catalogue, too—it wouldn't be free and post free if it weren't; but don't hesitate to write for it because you can never send me an order—if I may say so—it isn't your order I'm after, it is your appreciation.

THE GARDEN

VOL. LXXXVIII.—No. 2760. OCTOBER 11, 1924.

WE WOULD ASK OUR READERS TO REMEMBER THAT "THE GARDEN" IS PRODUCED FOR THE BENEFIT OF ALL GARDENERS. WE ARE ALWAYS PLEASED TO CONSIDER ARTICLES OR NOTES ON ANY HORTICULTURAL SUBJECT. WE ARE ALSO HERE TO ANSWER QUESTIONS.

TULIPA KAUFMANNIANA, ONE OF THE FINEST OF TULIP SPECIES; THE COLOUR VARIES FROM WHITE WITH A YELLOW CENTRE TO A RICH SCARLET. BULBS SHOULD BE PLANTED IN THE LAST HALF OF OCTOBER OR THE BEGINNING OF NOVEMBER.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

LABELLING and LABELS

EARLIER in the year there was a considerable amount of correspondence in THE GARDEN concerning labels, but this correspondence presupposed a theory that most gardeners used labels, which they do not. I feel that it is now opportune to bombard my readers with a few remarks anent labelling. Of all diseases to which gardeners are most prone, inefficient labelling is the most deadly and the most insidious. This, of course, particularly refers to those who are interested in some special genus or are making a collection, for in this case a month's slackness in labelling will upset the whole of the plant names in a garden. If you have two plants together closely akin, one labelled and the other not, some day doubt will step in. You, or your gardener, will wonder whether the label applies to the plant in front of which it is placed, or some kind friend will tell you that the label obviously is meant for the other plant—and that is your undoing. I am just as slack in this respect as anybody else. I put off labelling until I become alarmed, and then I rush helter skelter into a welter of labelling; my memory refuses to bear its burden and I label a plant A, which it is not—and so the merry round goes on.

From the number of plants—often quite common plants—which are sent to this office for naming, it is certain that few people trouble about the correct name of a plant, for it is obvious that for every one who sends in a plant to be named there are a dozen who will not take the trouble. There is one fact that is certain, and that is that labelling is a necessity for all who aspire to rise above the beginners' class in gardening. And if you come to think about it, it is not so very difficult or laborious; there is only one rule to be observed. Write a label for every packet of seed and for every plant, before you sow the seed or plant the plant. Do not wait until the end of the day, and write all your labels at once, for this is how mistakes occur. If this rule were adhered to, there would not be so many faulty names in our gardens. A great deal of information can be given on the label without overcrowding—the name, where it came from, and when the seed was sown or the plant planted.

From the correspondence in THE GARDEN there appears to be a great divergence of opinion about the kind of label to use. This is a personal matter, for you may like your labels inconspicuous and so placed that only you know where to look for them, or you may like them so easily seen that your garden looks like a graveyard. I prefer the happy mean, and after several years of experiment I believe that I have found a perfect label. It is made out of a sheet of thin celluloid, a substance so easy to cut that your labels may be of any shape or size you like. As far as my experience goes, it is practically imperishable; wet does not rot it nor sun bleach the lettering. For seed pans or annuals an ordinary pencil is quite sufficient. Even when covered with mud from the drip of trees, the mud is easily brushed off and the name is as clear as ever underneath: an ordinary rubber is all that is required to erase the writing when the plant is removed from the seed pan or is dead. For permanent plants special xylonite ink, which can be used with ordinary pens, is all that is necessary. The writing will last as long as the label. For seed pans or nurseries white celluloid can be used, but this is a little startling in a rock garden, so the celluloid is now dyed, and you can buy it of a most excellent fawn colour which is sufficiently inconspicuous and yet clearly seen.

Naturally, this label will never oust the cast or enamelled labels, but celluloid is far less costly and labels can be prepared at home, which is impossible in the case of the moulded labels. They are surely cheap and flexible enough for nurserymen to tie to plants before despatch and thus do away with an extra labelling, for nurserymen's labels are notoriously short-lived. I for one would be perfectly willing to pay an extra penny or two for a plant which I knew was durably labelled. A new slogan might be invented. "Say it with labelling": at any rate, it makes better sense than "Say it with flowers."

THE LARGE-FLOWERED HYBRID CLEMATISES

BY A. G. JACKMAN.

WHEN WELL GROWN, THESE ARE AMONG THE MOST BEAUTIFUL OF HARDY CLIMBING PLANTS.

IT is upwards of sixty years since the clematis first came into favour as an ornamental climber, and notwithstanding the improvements and more recent introductions in other climbing plants, it is still unrivalled for beauty and elegance. The introduction of the first species, C. Viticella, into this country dates back to 1569, and according to Loudon it was known in English gardens as the Virgin's Bower, this name being possibly intended as a compliment to Queen Elizabeth, who liked to be called the Virgin Queen. The name has also been immortalised by Cowper:

> Thrive gentle plant! and weave a bower
> For Mary and for me,
> And deck with many a splendid flower
> Thy foliage large and free.
> . . . . .
> Thy cause with zeal we shall defend
> And with convincing power;
> For why should not the Virgin's friend
> Be crowned with Virgin's Bower?

One wonders what eulogism Cowper would now have bestowed upon the various hybrids sprung from his Virgin's Bower.

Other species familiar in our gardens are CC. Flammula, paniculata, montana, montana rubens, graveolens, and the herbaceous species CC. recta and integrifolia. These are so well known that they require no recommendation, but there are others which are equally worthy of attention. Among these might be mentioned CC. crispa and campaniflora, both of which bear fragrant bell-shaped flowers. CC. tangutica and tangutica obtusiuscula are rampant-growing yellow species from Mongolia, C. Armandi an evergreen climber with panicles of white flowers from China, the winter-flowering evergreen C. calycina and C. cirrhosa from Southern Europe bearing spotted creamy yellow flowers, C. alpina a blue species from the Alps, the herbaceous climbing Texas species, C. coccinea with bright scarlet and orange flowers, and the two herbaceous perennials C. Davidiana with hyacinth-shaped sky blue, sweet-scented flowers, and C. grata or C. Jouiniana bearing panicles of bluish white flowers in great profusion. This article, however, is mainly concerned with the various large-flowered hybrids. These for size, beauty and diversity of colour far surpass the species. The various purposes to which they can be applied render them invaluable as decorative plants. Few climbers can surpass them for covering a wall, climbing an arch or pillar, or over trelliswork, covering tree stumps, rambling over bushes, or growing in a conservatory or cool greenhouse in either pots or tubs, or planted out in the border. Several varieties of the Jackmanni and Viticellæ sections are also adapted for pegging down in beds.

It has been found desirable from a horticultural standpoint to classify the hybrids into six distinct sections, combining varieties of similar characteristics and season of flowering. This classification will be found of assistance in making selections, and will act as a guide to their pruning and the various purposes to which they can be put. They are:

1. Azuræ type.—Climbing large-flowered spring bloomers (May–June), flowering from the old or ripened wood.

2. Floridæ type.—Climbing large double-flowered summer bloomers (June–July), flowering from the old or ripened wood.

3. Lanuginosæ type.—Climbing large-flowered summer and autumn bloomers (June–October), flowering successionally on short lateral summer shoots, the flowers dispersed.

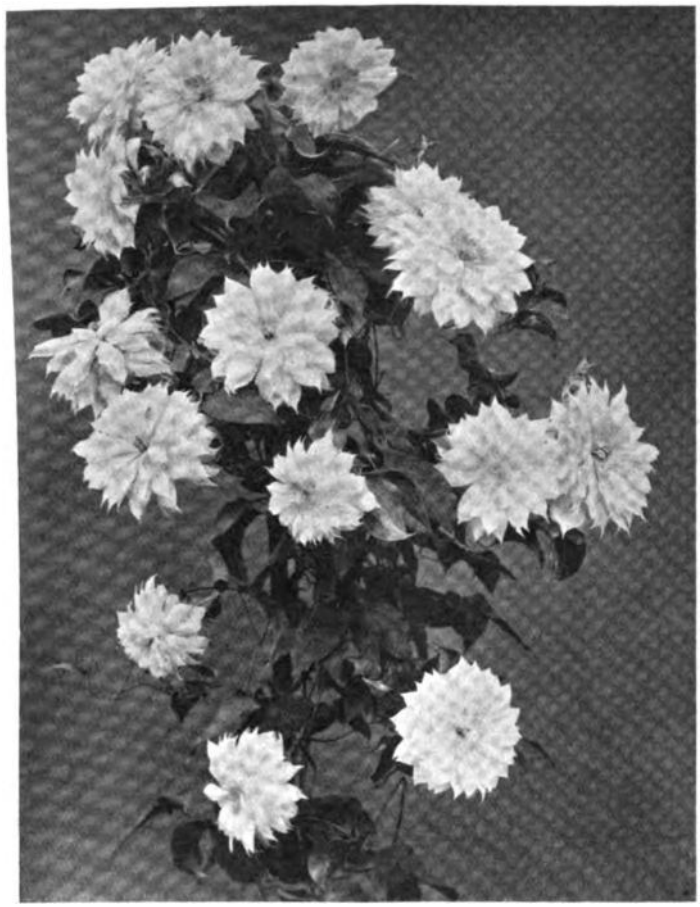
4. Jackmanni type.—Climbing large-flowered summer and autumn bloomers (July–October), flowering continuously in profuse masses on the young or summer shoots.

5. Viticellæ type.—Climbing large-flowered summer and autumn bloomers (July–October), flowering successionally in profuse masses on the young or summer shoots, but not so continually as the preceding.

GRAND DUCHESS, A NOTABLE INTRODUCTION OF RECENT YEARS.

THE MOST FREE-FLOWERING PURE WHITE VARIETY IN CULTIVATION, THE BRIDE.

Digitized by Google



BELLE OF WOKING. A SUB SHRUBBY TYPE WITH PROFUSE MASSES OF BLOOM.

6. Wokingensis type.—Climbing sub-shrubby, medium-sized, campanulate, summer and autumn bloomers (July–October), flowering successionally in profuse masses on summer shoots.

The clematis thrives in most soils where the drainage is good, but, where procurable, a rich loamy soil will be found the best, to which may be added some good rotten manure, chalk or slaked lime. The hole should be dug at least 2ft. square by 2ft. deep. The plant should be carefully taken out of the pot in which it has been growing and the crocks removed, particular care being taken not to damage the shoots or roots. It should then be placed in the hole so that when filled in the top of the ball is about 2ins. below the surface of the soil, the earth being made firm round the plant.

The clematis prefers a partly shaded position. An easterly or westerly aspect is therefore preferable to due south, as the plant thus escapes the full blaze of the sun during the summer months, or a position where the roots are partly protected by adjoining shrubs or plants is also advantageous.

When required for growing in pots or tubs in the conservatory or cool greenhouse the clematis should be re-potted in March, and the young shoots trained into the position required. The temperature of the house should not exceed 55°, otherwise the flowers will not show their true character.

Pruning is an important operation, and should take place in February or early March.

The varieties of the spring-flowering Azuræ and Floridæ types which flower from the old wood only require the weak, straggling or overcrowded shoots removed, while the summer and autumn flowering varieties of the Lanuginosæ, Jackmanni and Viticellæ types which flower from the young shoots may be cut back to within two pairs of axillary buds, the aim being to encourage the development of vigorous young shoots. It is advisable, however, to defer this operation until the plants are thoroughly established. The varieties of the Wokingensis type should have the shoots cut back to where they have died down.

With so many fine varieties it seems almost invidious to mention names, but among those that have been introduced in recent years mention might be made of Nelly Moser, Lasurstern, King Edward VII, Lady Northcliffe, Lady Betty Balfour, Belle of Woking, Grand Duchess, Countess of Onslow, Duchess of Albany, Admiration and the two latest novelties, Crimson King, the brightest of all the reds, and The Bride, the most free-flowering pure white variety in cultivation, forming, indeed, a veritable bridal bouquet.

It is of interest to note that although C. Jackmanni was introduced over sixty years ago, it still retains its position as general favourite, and the name has been immortalised by Tennyson in his poem "The Spinster's Sweet-Arts":

An' I sits i' my oän little parlour,
An' sarved by my oän little lass,
Wi' my oän little garden outside, an'
My oän bed o' sparrow-grass,
An' my oän door-porch wi' the woodbine
An' jessmine a-dressin' it greeän,
An' my oän fine Jackman i' purple a
A roäbin' the 'ouse like a Queeän.

TULIPS AND THEIR CULTIVATION

BY C. W. NEEDHAM.

TULIPS are of two main sorts, in regard to colour; some have sap colours only, white or yellow as the case may be, others, in addition to the sap or mesophyll colour, have a pigment colour on the face of the inner side of the skin of the petal.

The whites and the yellows, without pigment colour, are the true selfs; those tulips having pigment colour on the epidermis of the petals, in shades of varying intensity of rose or purple, give coloured flowers; sometimes, in addition to this antho-cyanin pigment, there is present a yellow pigment, related in some way to the antho-cyanin pigment, and this gives the "shot" effect to the colour of the petals, as in John Ruskin; this yellow colouring matter in the segments rapidly fades as the bloom ages.

The rose and purple pigments on the white grounds give us the "roses" and byblœmen, or, to use the old English name, "purples."

Again, similar rose and purple pigments coming on the yellow grounds—sap colours—give us the red bizarres and the brown bizarres.

Tulips are divided into roses, byblœmen or purples, and bizarres. The roses and the byblœmen are on white grounds and the bizarres on yellow grounds.

In many tulips there is colouring matter in the blotch round the seed vessel, that is, in the blue or black base. English tulips have pure white or pure yellow bases. In speaking of the colour of a tulip bloom the base is neglected.

More than a hundred years ago the colour divisions were mainly yellow grounds and white grounds, bizarres and byblœmen. The white grounds only were esteemed by the early Flemish and French florists; the bizarres were discarded.

Soon after the introduction of the tulip into Europe about 1550, florists were at work on the flower, raising new varieties from seed, even though numerous varieties were already in existence, apparently owing their origin to the Turks. Flemish, French and English florists devoted their attention to the improvement of the flower, which had rapidly come into favour with all who cultivated it. As the outcome of the work of those who loved the flower and best knew its possibilities, a standard of perfection seems to have been evolved. This standard was not so much of an arbitrary dogma as an expression of what was most desired and an indication of the form in which the tulip could show itself to the best advantage.

Thus we got the florists' ideal of a tulip, its shape should be about one-half of a hollow ball when the flower is expanded,

Digitized by Google

so that at one glance we may see the whole interior of the bloom. Its stem should be stout and erect, carrying the bloom well, and its colours should be pure and clear, the results of a basal ground of pure white or clear yellow. The petals should be broad, rounded and nicely imbricated, level on the top and making a perfect cup.

At all events, that was the English ideal. The Dutch had more regard to brilliancy of colour than purity of base, and with them the shape of the flower was unimportant.

On the first occasion of noticing tulip bloom one is attracted by its mass of colour, which arrests one's attention; then interest is awakened in its general form and appearance; later comes an appreciation of its merits and, from a delight in splashes of bold, gay colouring, we pass on to the desire for the soft tones—the melting shades; we go from contemplation of the yellow, the red and the purple to the appreciation of the intermediate tones and shades of colour. From the definite purples to the bewildering and fascinating shades of lilac and lavender, soft and dreamy, on through the suggestions of the blue into the blushes and pinks to the roses, indeterminate at first, then into bold, bright reds and on through the orange golden and yellow shades. Down the whole chromatic scale the eye moves, finding the expression of one's thoughts of the moment in the selected shades, whether indefinitely suggested and delicate in tint, or decided, unmistakable and bold in colour, nebulous and dreamy, or wide-awake and strong.

Some tulip blooms delicately hint at a shade, others speak out boldly in a decided way.

Observing some of the very old types and comparing them with some of the more modern types, we note the results of the efforts of the old florists at work among the purples with their white grounds, separating the reds from the blues and getting clear and distinct shades, and among the bizarres with their yellow grounds, brightening the reds and intensifying the purples, until on the one hand we see orange and gold in conjunction and on the other hand a shade of purple, almost black, superimposed on a lemon yellow ground. These results point the way for future florists to tread when putting their faith into practice in the raising of seedlings that shall surpass any known variety. Maternity completes womanhood, seedlings complete the florist.

The Flemish and French florists of old appear to have preferred the white ground tulips to the yellow grounds, and devoted themselves to the improvement of the byblœmen section, neglecting the bizarres. One is tempted to ask, is there any connection between their devotion to the byblœmen section and the facts that the white grounds seem dominant and the yellows recessant in seedling raising?

The section of May-flowering tulips called Darwins, introduced into commerce about twenty-five years ago by Krelage, appear to have been the work of some inheritors of the Flemish and French tradition, since the yellow grounds are entirely absent from the group, which appears to have been bred for a sound constitution.

The characteristics of the Darwin are its sturdiness and robust habit, its flowers being rather square-shouldered, its petals take off the stem almost at right angles and turn again at a sharp angle to form the cup; the unopened flower seems wedge-shaped.

The old Dutch florists' tulips are mainly egg-shaped in the bud and their petals long and brilliant in colouring.

The English florists' tulips have shorter rounded cups and clear pigment colours on pure white or clear yellow bases.

In the old days, a fine tulip meant a broken tulip; the selfs or breeders were appreciated for the inherent power they possessed of breaking well or badly. In these modern days tulips are more generally appreciated in their self-coloured or breeder stage. The English tulips were bred to break and to break well.

All tulips having the pigment colour before described will break at some time or other, whether they be Dutch, Darwin, English or Cottage tulips. Broken Darwins are commonly called Rembrandts. Yellows and whites, being true selfs without the pigment colour, do not break.

Tulips which are not Dutch or English florists' types, or Darwins, generally fall into the group called Cottage tulips. They are, doubtless, many of them, discarded florists' varieties which have survived owing to their sturdiness and persistent vitality. Tulip species are rare treasures.

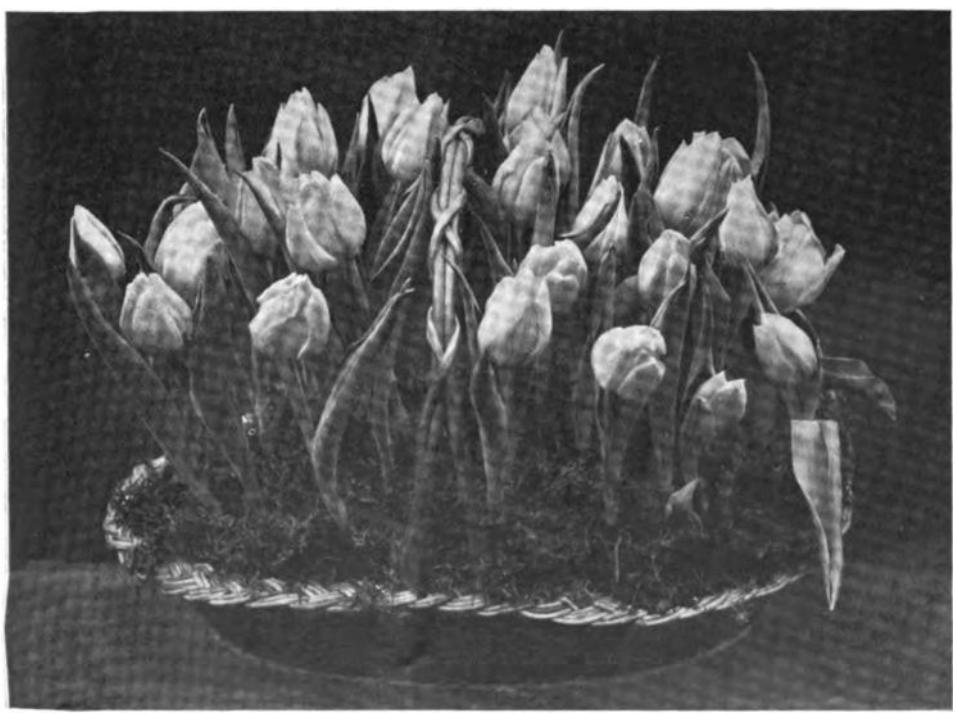
Of the early-flowering varieties the dwarf bedding flowers which may be expected to bloom in March or early April, the earliest, and some of the best, are the Duc Van Thol tulips in shades of red, yellow and white. Their price is usually about 15s. per 100, and very effective they may be made, grown in masses of colour schemes. There are other early but taller varieties, usually flowering in April or early May, suitable for bedding in groups of colours, embracing White Swan; in scarlet, Dusart, Artus, Couleur Cardinal, in height 14ins. or 15ins. or thereabouts, in decided bright colours; in red and yellow we have Duchesse de Parma with clear bright shades and a large yellow base and short cup, and an old-time flower, Keizerskroon, of red body colour with yellow feathering on the edge of its petals, once as plentiful as Emperor daffodil is now. It is very effective grown in a bed with wallflowers, the bloom is bold, of goblet shape, and lasts well.

The Duchesse is an especial favourite, its substantial petals are often delicately pencilled with red, though occasionally one sees a vase of the breeder type such as was shown in a group of old tulips by Messrs. Bath at an early meeting of the R.H.S. in May last. Messrs. Bath, by the way, had also examples of orange-scarlet in Grenadier and Prince of Austria, and both are fragrant.

Another example of an orange shade is Fred Moore, also scented, about 18ins. in height, having a starry base and being fairly cheap as quoted by Hogg and Robertson.

In yellows we may select from Montrésor, Chrysolora, King of the Yellows and Prince de Ligne, which grow 13ins. to 15ins. in height. A bed made of the crimson-coloured Macrospila, a form of Gesneriana, is most pleasing and gives off a fine perfume after rain. The bulbs are cheap.

In selecting varieties for the garden it is well to seek guidance from the nurseryman's catalogue for the economical expenditure of one's money as well as the satisfaction of our wants. Some lists are instructive; Barr's is notably



ONE OF THE CHOICE YELLOW VARIETIES, TULIPA MONTRESOR.

Digitized by Google

informative—experience shows it to be a veritable index, carefully compiled, though most lists give useful details.

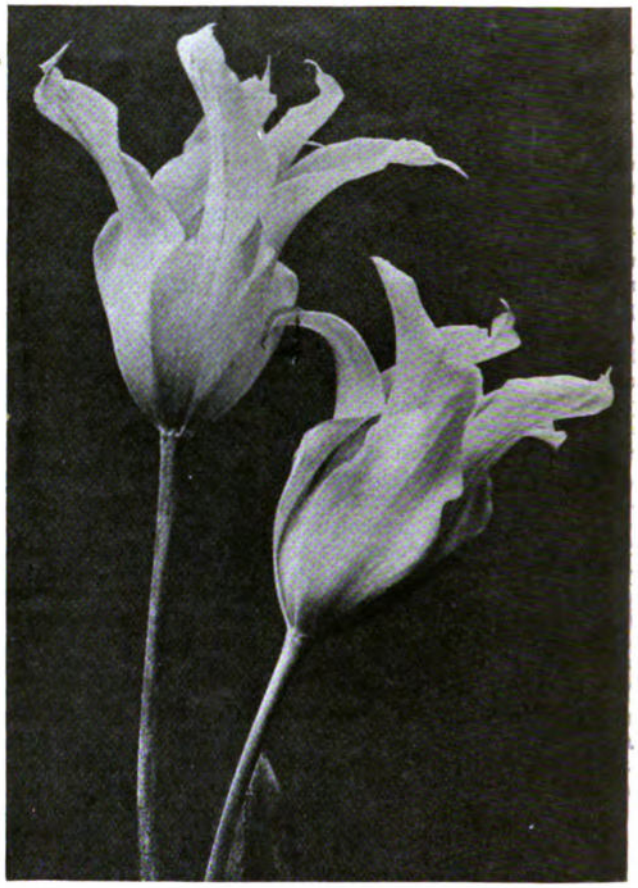
Among the Cottage varieties, there are, in crimson:

Gesneriana-spathulata, a type. In scarlet colours: Grand and Scarlet Emperor, about 2ft. in height. In orange-scarlet: Orange King and Grenadier, both scented and about 20ins. in height. In yellow: Mrs. Moon, with pointed petals; Gesneriana-lutea, Bouton d'Or and Inglescombe Yellow. Bouton d'Or in a bed by itself and "well done" makes a fine display of large blooms. Inglescombe Yellow is somewhat later in blooming, but gives noble flowers. Both are very suitable for cutting and grow about 2ft. high. In primrose shades there are Solfatarre and Vitellina.

Prince of Orange is a delightful old Dutch tulip, perhaps the best one in bright red with a flush of gold; it deserves a special place and it lasts well. The bulbs may cost 3d. each; the blooms will be priceless if the plant is well grown. Other fine old Dutch tulips are Velvet King, a purple; Dom Pedro, a bizarre; and Bacchus, another purple. This last may cost 9d. per bulb, but it is worth it.

A quaint yellow tulip is Retroflexa, and a green one with waved petals is Viridiflora. A pretty little brown dwarf tulip is Persica and suitable for rock gardens. Præstans is orange-red in colour and often has four or five blooms on a stem; it comes from Bokhara. Sprengeri is orange-scarlet and the last tulip to bloom. Saxatilis is a delicately shaded satiny rose. Sylvestris, a sweet-scented typical tulip from the Caspians. Fosteriana, from Bokhara, is one of the most brilliant scarlet red tulips, long in the petal and an early bloomer; some have clear yellow bases, others have blotched blue bases; the bloom is a very bright feature in the border in late April.

Kaufmanniana, from Turkestan, is another gorgeous bloom when it comes Turkey red in colour; some blooms are creamy yellow. Extremely interesting is this tulip species. The bulbs of many of the species tulips have to be collected and imported, so are not very low in price, nor are they easily propagated here in this country, though easily grown.



TULIPA RETROFLEXA, A YELLOW WITH RECURVED BLOOMS.

A MAHOGANY-COLOURED BIZARRE, DOM PEDRO.

Turning to the more popular Darwins, we have in shades of vermilion Isis and Glow. Isis has rather a waxy coral look and comes into bloom somewhat early. We have Europe, with a clear base of white showing up well its beautiful shade of red, 26ins. high; and Mrs. Farncombe Sanders, with big bold square-looking red blooms standing 30ins. high, a notable variety; and the vigorous cerise-coloured bloom, Pride of Haarlem.

For shades of rose, there are: Baronne de la Tonnaye, a soft pink, tall, with a stem of 30ins.; the bloom has a slight "waist." Sought after as a cut flower. Julie Vinot is a sweet shade; and Loveliness shows itself well, the base being white. For a pale shade of rose there is the option of Psyche, over 30ins. high, and Suzon, about 28ins. tall. In salmon-pink shades comes Clara Butt one of the very popular flowers. In the purple shades we have Moralis and The Bishop—even though the latter is somewhat "eminent" in price. In lavender shades are Rev. H. Ewbank and Sweet Lavender, both over 2ft. in height. For lilac shades, Erguste and Electra, both having white bases; Dorothy, whose white base is blotched with grey; and the noble Philippe de Commines. Another mauve shade is Bleu Aimable. The two last-named varieties grow about 30ins. in height. Remembrance is a slaty lilac; also La Tristesse, which seems slightly tinged with yellow. Mrs. Potter Palmer is a rosy lilac shade, and Euterpe similar in shade but showing its tints off better because of its white base. For a blush shade there is Margaret, a very pretty bloom. Then we have the palest of the Darwins, White Queen.

Since "we must have blooms for the house," and in mid and late May flowers for vases are somewhat scarce, tulips offer themselves as a ready prey, as well for their decorative as for their lasting qualities. If one must cut tulip bloom it is well to select bulbs for the purpose and grow them in a spare bed, and thus preserve the flowers that are grown for display, decoration and delight in the garden.

A SEASONABLE NOTE ON GREENHOUSE HEATING APPARATUS

THE approach of autumn should give warning to all who possess greenhouses to make ready for winter. Many a tale of trouble and disaster could be told of heating apparatus left severely alone throughout summer and found to be defective at a critical time when an enforced wait for new "parts" or competent labour has involved serious loss of valuable stocks of plants.

It is an extraordinary thing that despite the costliness and the supreme importance of the whole system of heating apparatus very many owners and controllers of gardens are guilty of neglect of this particular subject of consideration.

Fuel is costly, and in order to extract the maximum value or heating capacity from the fuel used it is essential that the heating apparatus shall in the first place be adequate to the demands made upon it; secondly that the installation shall be accurately planned, and thirdly that the whole shall be maintained in a thoroughly efficient manner.

It has very frequently occurred that economising in the matter of heating arrangements has started at the wrong end. A small boiler attached to a greater amount of piping than it is really capable of dealing with must be driven so hard that fuel consumption is excessive, and the wear and tear of the boiler is destructive.

Too small a quantity of piping for the cubic capacity of the house is equally bad, for that again means constant hard driving, waste of fuel, and strain on the boiler. The truly economical course is to have an adequate supply of piping, and a boiler of sufficient power to maintain a good temperature with quite moderate fires. Fifty feet of 4in. piping to every thousand cubic feet of space in the house is a satisfactory average, capable of easily maintaining a temperature up to 60°, which is high enough for all general purposes. The size of the boiler should always be 25 per cent. larger than that which would represent maximum power in relation to the quantity of piping. These are important points because they have a very direct bearing upon annual expenditure in fuel and in repairs, and in the event of necessity arising for repairs of considerable extent it is highly advisable thoroughly to investigate and ascertain whether a larger boiler or more piping is required. Waste of fuel is very often the outcome of a worn out or broken furnace bottom. A broken bar will allow unburnt or partially burned fuel to fall through to the ash pit. If that continues throughout the winter a large amount of fuel will be wasted. A new single bar may be put in at moderate cost. A cracked boiler will cause no end of trouble, and will be a constant cause of waste in expenditure as well as a source of annoyance. A cracked furnace door, or broken damper will also prevent satisfactory control of the fires. Generally speaking such features may be successfully welded by oxy-acetylene blow pipe, the modern method of perfectly healing broken metal without the old-fashioned patch and rivets.

Leaky joints in hot-water pipes should receive attention before winter sets in, as it is a risky business to have to empty and take down pipes during a spell of keen frosty weather. There is an immense advantage in having rubber expansion joints, and even where these are not already installed it is worth while to introduce them whenever a new length of pipe is fixed. Rubber-jointed pipes may rank as tenant's fixtures, but cement-jointed pipes are not entitled so to rank.

Furthermore, breakages frequently occur when disconnecting cemented joints, but with rubber expansion joints the task of disconnecting and re-fitting is simple.

An immense amount of trouble is caused through furring of the interiors of boilers and pipes, especially where water contains much chalk. Acid preparations are procurable which will dissolve the incrustation, but the fluid is expensive, and needs to be used with caution, for it will, if allowed to remain, also eat into the metal with disastrous results.

Sometimes pipes are so badly furred that something must be done, and in such circumstances the best plan is to procure sufficient diluted nitric acid, obtainable from merchants in commercial chemicals, pour them (with water) into the cistern, and put on a driving fire for a while. Be careful to turn all safety-valve taps on, as the acid will generate gas in the pipes. After the water has been driven round the pipes for an hour, and while still hot, draw all off from the boiler tap, using old buckets for the purpose. Let the fire down, in the meantime to prevent cracking the boiler, and when the boiler and pipes are empty and cool run a quantity of clear water through and out, to wash away as far as possible all trace of the acid. This means much labour, but it will save the situation so far as restoring the system to workable order, and will effect a great saving in the consumption of fuel. Indeed, every hot water installation should be thus flushed out at the beginning of every season, for no matter how careful one may be in using clean water for filling up the cistern, some impurities are bound to find an entrance to cause a sediment in the pipes. If there is much sediment the tap may be choked, and it will be necessary to take it out, permitting the unhampered escape of water and sediment. Always empty while the water is hot, and in active circulation, but always take care that by the time the pipes are emptied the fire is out.

There are those who maintain that it is unnecessary to empty the boiler an pipes for the period of the year when fires are not in use, but that appears to be a view which looks upon saving of labour as being the most important consideration. It cannot be beneficial to have stale, stagnant water remaining continuously inside the heating apparatus, and I would certainly urge that the better plan is to empty at the end of the firing season, flush out and refill at the approach of autumn.

See that all safety valve taps are open when refilling, and make quite sure that the pipes are quite full before lighting the fire.

The question of what shall be done to maintain a neat and tidy appearance of the hot-water pipes needs some consideration. The chief point is that nothing must be used which will give off injurious fumes when the pipes are heated.

Japan black or Brunswick black are sometimes recommended, but they can only be used when the house is empty, and it is necessary to have two or three fires to heat the pipes and exhaust the poisonous fumes before plants are brought into the house.

A paint made of graphite and pure boiled linseed oil may be used with safety in occupied greenhouses. It will give off a strong odour when first the pipes are heated, but the fumes are non-poisonous, and harmless to plants. Beware of cheap paint-oils which are frequently offered as being as good as linseed oil. These are frequently extracted from fish, and are quite unsuitable for the purpose under present consideration.

In commercial houses whiting is often used for coating pipes, and if a good quality of painters' driers is mixed with the whiting it will not readily rub off and the pipes will at any rate be kept clean and rustless.

Finally look to flues, chimneys and soot traps. It is surprising how often unsatisfactory fires are endured for long periods, the setting of the boiler, height of chimney and lack of under-draught all being held to blame, while the real reason is that flues and chimney are choked with soot and shale. Rake and clean out the whole of the smoke channel, and from time to time throughout the winter repeat this operation. Many a troublesome furnace will become easily manageable as a result of this precaution, but if despite of cleanliness the draught is defective, try the effect of a taller chimney-pot or a "cowl" on the top.

There is no doubt that irksome and laborious as the task of overhauling heating apparatus may be it is in the long run a means of saving labour and vexation, while the cost of essential repairs is money well invested which may very probably save several times the amount.

A. J. MACSELF.

USEFUL SEMI-HARDY SHRUBS

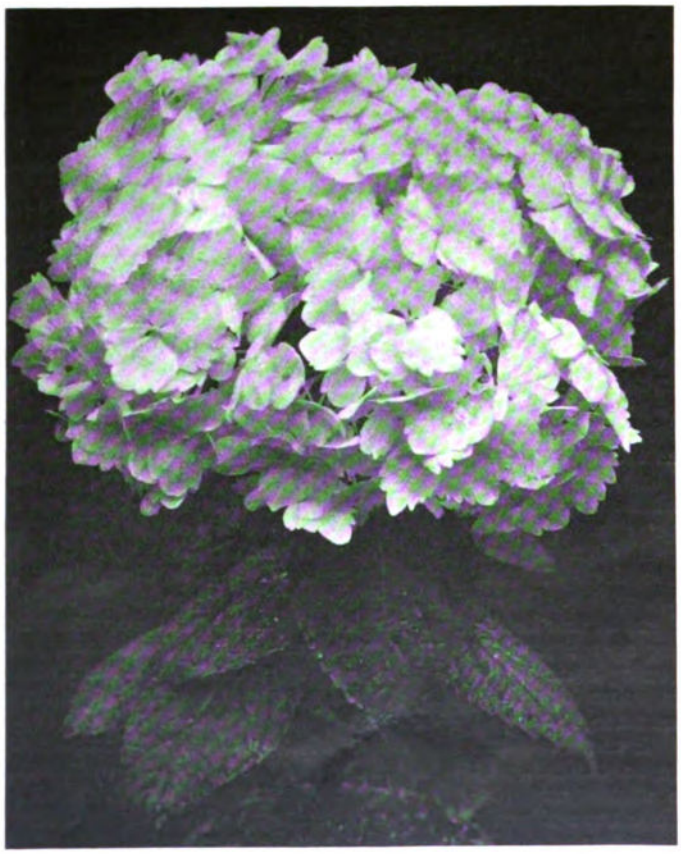
HYDRANGEAS ARE HIGHLY ORNAMENTAL LOW-GROWING SHRUBS, THRIVING WELL IN PARTLY SHADED POSITIONS, BUT FLOWERING MORE FREELY IN FULL SUN IF THEY ONLY HAVE SUFFICIENT MOISTURE.

WHEN hydrangeas are mentioned, one usually thinks of Hydrangea hortensis, no doubt because it is the most popular. The reasons for this are not far to seek when one remembers that it was introduced in 1740 and has given rise to more distinct varieties than any other. Recent introductions give the impression that it is almost capable of giving as much variation as a zonal pelargonium, and this idea is strengthened by older introductions from China and Japan, which vary greatly in leaf, stem and flower. The common hydrangea can be most successfully cultivated only as a greenhouse plant in most parts of Britain as plants from 1ft. to 3ft. high, though the writer has seen a pot plant 6ft. to 7ft. high and as wide. It was carefully staked to give the foliage the full advantage of light. Exhibited regularly at a local show it got larger every year until it dominated the big tent, and could not be overlooked.

THE HARDY AND MOISTURE-LOVING HYDRANGEA PANICULATA.

CULTIVATION.

Presuming that the plants have been wintered in a house from which frost was just excluded, they may be repotted in February or March, according as they are desired to be in flower, early or late. It will be an advantage if the plants are subjected to a little heat to excite them into fresh growth. When the buds are well started, the old balls may be reduced more or less and the plants re-potted into pots of suitable size. Drain the pots well. A good compost consists of one part loam, two parts peat, two parts leaf-soil, and sufficient sharp sand to make it porous. The potting should be done with moderate firmness. Water them with a rose on the can to settle the soil and place them back in the greenhouse. They should be watered with discretion at first, but as growth advances they will take clean water more and more frequently. When the flower-buds appear, weak manure water should be given twice a week, or some approved fertiliser may be used. As the buds begin to develop colour, the feeding should be gradually decreased and, finally, omitted altogether. In proportion to the heat of the house, atmospheric moisture will increase the size of the flowers; but as the blooms reach perfection more ventilation and a lower temperature will prolong their life. The house should be shaded on bright days, otherwise the colours will burn and the flowers be short-lived.



A HANDSOME SHRUB WITH SHOWY WHITE BLOOMS. H. MME. MOUILLERE.

As soon as the plants cease to be ornamental they should be pruned back slightly, and kept drier for a time till they break into fresh growth. They can then be repotted in a similar compost to that previously mentioned. By the time they are growing freely the weather will be suitable for standing them outdoors for the summer to make and mature their growth. Some feeding may be given for a time to promote good growth if considered necessary, but this should cease in good time to enable the wood and buds to mature properly before autumn is too far advanced.

Plants that are flowered in unheated houses or in the open air should not be pruned in the above way, because they will have no time to mature their young growths before the end of the growing period. The stems or shoots that have flowered may be cut back, more or less, to a good bud, and the leafy, unflowered shoots let severely alone to bloom the following year.

PROPAGATION.

Cuttings are easy to root in spring or early summer in a little bottom-heat. Those struck thus early can be pinched and kept growing to produce several heads of flowers the following year; but those rooted from midsummer onwards should be put singly into 3in. pots and shifted into 5in. pots as soon as they are well rooted. These late plants may be grown in a cold frame more or less tilted up at the back, watered and fed till they make a sturdy growth of 4ins. to 6ins., when the lights should be drawn right off to mature the wood and plump up the flower-buds. If well grown, these plants will give a single, large head of bloom suitable alike for the greenhouse

Digitized by Google

or home decoration, and they will submit to forcing quite early in the year.

OUTDOOR CULTURE.

Near walls or fences, facing south or west, Hydrangea hortensis and its varieties can be grown as ordinary shrubs from the south coast as far north as Middlesex at least. Near the southern and western seaboards the plants make large bushes, and the flowers assume beautiful shades of pink, lilac, metallic shades of blue and bright blue, without any special treatment. Under glass the flowers are changed to blue shades by treatment with alum, sulphate of iron, cyanol and blueing powder. Modern varieties that respond well to blueing are Viscomte de Vibraye, Mme. Chautard, Maréchal Foch and La Marne. Other handsome modern varieties that may be grown outdoors as shrubs, as well as under glass, are Mme. E. Mouillère (white), Germaine Mouillère (white, fringed and of huge size), Etincelant (bright carmine and free) and Elmar (carmine-red). To these may be added H. Lindleyi (white, tinted with pink) and H. L. albo-rosea (white, shading ultimately to deep rose). Both have small leaves, though belonging to H. hortensis; they recently received awards of merit from the Royal Horticultural Society. Other varieties are H. h. Mariesii with large, mauve, outer flowers, and H. h. nigra, with dark blue stems, and worthy of cultivation.

HARDY SPECIES.

The most popular and best of the hardy species is the Japanese H. paniculata grandiflora, having all the flowers barren, enlarged, white and produced in an elongated panicle. The largest heads are produced by growing the plant as low bushes and cutting them down annually to about three buds of the young wood early in March. It can also be grown as a bush 8ft. to 10ft. high, with a wealth of smaller panicles that come to their best in August and September. The best of the American hydrangeas is H. arborescens grandiflora (or sterilis), which blooms from early June till frost, and has all the flowers barren and white. It is known in America as the ever-blooming hydrangea, and was introduced to commence in 1907, though it was grown privately by the discoverer and others for eight or more years previously. It was a wild find and not improved in cultivation.

Hydrangea quercifolia also comes from the United States, and is a fancy plant for the collector. The large, lobed leaves are very striking, but only the outer flowers are enlarged, sterile and greenish white or pink. It should have a sheltered position for the sake of its leaves, though not necessarily a warm one. The Japanese H. petiolaris (scandens) may be grown as a wall shrub or planted as a sprawling bush to ramble over the rocks in a large rock garden. The outer flowers are enlarged and white. Another very striking fancy species is H. Sargentiana, with leaves often 10ins. in length. Most of the above are in commerce at the present time and many more, especially in varieties of H. hortensis; and many of them are valuable because they bloom so late when most other shrubs are out of flower. J. FRASER.

RESULT OF THE ROSE COMPETITION

It is exceedingly gratifying to us to see how popular our Rose Competition has been among our readers, for from the thousands of lists sent in by competitors it is obvious that the rose is still one of the most popular flowers. The number of entries exceeded even our sanguine expectations.

The result by popular vote of this Competition is as follows:

1.—GENERAL McARTHUR

2.—OPHELIA

3.—MME. ABEL CHATENAY

4.—LOS ANGELES

5.—LADY PIRRIE

6.—MRS. HENRY MORSE

The winners are—

FIRST PRIZE, an order of £3 on any advertiser in THE GARDEN—

MR. E. WOOD, Goldsborough, Manor Road, Cheam, Surrey;

SECOND PRIZE, an order of £2 on any advertiser in THE GARDEN—

MR. E. D. BROSTER, The Gables, Wirksworth, Derbyshire;

THIRD PRIZE, any book published in the *Country Life* Library to the value of £1—

MISS KATHERINE ELLEN SHAW, Hatfield Place, Bath.

A Consolation Prize is awarded to

MRS. M. F. HULTON, Cat Hill, East Barnet.

IT might interest our readers to know that General McArthur was voted for by 56·8 per cent. of the competitors, Ophelia by 49·3 per cent., Mme. Abel Chatenay by 42·7 per cent., Los Angeles by 42·4 per cent., Lady Pirrie by 36·9 per cent., and Mrs. Henry Morse by 24·2 per cent. It is, therefore, probable that General McArthur is by a long way the most popular Hybrid Tea in existence. After Mrs. Henry Morse the voting on other roses dropped away suddenly, the next most popular being Caroline Testout with under 16 per cent. of the votes. It is amazing how quickly Los Angeles introduced in 1916, and Mrs. Henry Morse introduced in 1919, have gained a position among the first six Hybrid Teas, and this only proves in how short a time a rose of high quality spreads through the country.

THE GARDENS AT WEMBLEY

THE gardens at Wembley fall naturally into three sections: those made and maintained by the Exhibition authorities; the exhibits of the horticultural trade; and the gardens attached to the Dominion and Colonial buildings.

We have already remarked upon the great work of making the large flower garden at the Wembley Park entrance, the long stretch of flower beds in the main avenue; the huge rock garden and the tasteful slopes on the south side of the lakes which provide an Empire waterway from New Zealand to India. Besides these important features, the Exhibition authorities have made themselves responsible for the gardens in front of the great Palaces of Industry and of Engineering and the raised beds which point the way to H.M. Government Building in the eastern section. Mr. E. White is responsible for this department.

The rock garden has proved to be an attraction to certain of the visitors, who have delighted in resting there in comparative quietness to enjoy the generous breadths of colour provided by thousands of Dianthus Allwoodii which have made the chief floral display since the Darwin tulip faded. On the north side of the lake the wallflowers and tulips have been succeeded by the brilliant bedding Dahlia Coltness Gem associated with white marguerites. For some reason not readily apparent, the fullest use is not made of the large handsome vases which break the long line of flower boxes. As a floral connecting link the two long lines of the dahlia are joined at the central flagstaff by the new Salvia Harbinger, which flowers continuously and yet keeps very dwarf.

We suspect that "art shades" have been relied upon for the effect along the southern front of the two large buildings. The yellow of the wallflowers and pale pink tulips were replaced, in due season, by the soft pinks and yellows of bedding pelargoniums and antirrhinums, with occasional mauves and whites. While this scheme will, no doubt, find its admirers, we venture to suggest that such are in the minority and that the position backed by the long stretches of grey concrete rather called for bright treatment. A bolder lay-out would probably have also been an advantage. Generally the soft pink colour is provided by Pelargonium King of Denmark, which has too robust foliage for the narrow beds, and, though not so badly as with Victory, which is also used, the flowers burn, even in the present season.

The "general idea" in the large flower garden and the main avenue seems to have been identical. The wonderful display of Darwin tulips was apparently to be followed by successional herbaceous plants. Never before has any public been in a position to enjoy such a floral feast as that provided last spring by those glorious Darwin tulips. These, we understand, were all from British-grown bulbs—bulbs grown principally at Spalding and a large proportion given by one of the chief growers of bulbs in England, in order that the Empire public might have an opportunity of seeing that our home-grown tulips fully equal in quality those from the Continent. The large beds were planted with separate varieties, the colour blending was good, so that a wholly admirable effect was obtained. It seems a pity that this policy was not continued—and it is difficult to see how the method of relying on several different herbaceous plants in each flower bed could have been expected to provide the floral display the garden and circumstances demanded. At the moment a number of dahlias, which apparently had been grown in pots, brighten the garden considerably.

HORTICULTURAL EXHIBITORS' GARDENS.

A large area was at first placed at the disposal of the horticultural trade, but, unfortunately, the demand fell short of anticipations. Still, the trade gardens cover a considerable space and are of great value and attraction. These gardens are planted and maintained solely by the exhibitors.

Messrs. Dobbie and Co. have one of the largest gardens, where, in association with Mr. James MacDonald, who maintains the excellent grassed portion, they have had seasonable displays, commencing with a good selection of Darwin tulips, pansies, wallflowers and forget-me-nots. Many beds have been planted with an excellent variety of roses, while the dwarf bedding dahlias are still making a beautiful display. Next, Messrs. G. Jackman and Sons have made a most agreeable garden, which is now known as the "Garden of Remembrance," in honour of those who fell in the Great War—a charming thought. The garden has a well built freestone retaining wall and an ornate stone garden house. Roses chiefly occupy the flower beds, and these have been especially successful. The surrounding borders have been interesting throughout the season with a good variety of flowering shrubs, including the beautiful clematises which Messrs. Jackman grow so well. Roses are also prominently shown by Messrs. S. Spooner and Sons, whose beds and long borders have been very bright and gay.

The most popular garden in the horticultural section is that of Messrs. Watkins and Simpson, the wholesale seed growers. It is a raised garden surrounded by an uncommonly good, low hedge of Retinospora pisifera aurea. Three low flights of York stone steps give to well kept paths, surfaced with toned red ballast, leading to the elegant pavilion, where the firm's representatives receive enquiries. The garden, which was designed for Messrs. Watkins and Simpson by Mr. A. Cecil Bartlett, is in keeping with the handsome pavilion and of the type suitable for a small country house. All the plants were grown at Feltham by Messrs. Watkins and Simpson, who have kept the garden in first-class order. From the opening of the Exhibition this garden has always been bright and full of attraction. Wallflowers, auriculas and polyanthuses commenced the season, and as their period waned they were replaced with antirrhinums of splendid free-flowering strains, lobelias, marigolds, salpiglossis and many other of their excellent novelties. Perhaps the most noteworthy of the newest plants is their Salvia Harbinger, an exceptionally dwarf strain of S. splendens. Seed was sown under glass at the end of January, and the plants have been constantly in bloom since the beginning of May and even now are barely a foot in height. The spikes are large and of intense colour.

Messrs. Kelway and Son have an informal garden where they have displayed many of their excellent delphiniums, peonies, pyrethrums and, of late, gladioli in quantity and of delightful colourings. The Langprim sorts have been also robust and graceful. Adjoining the Kelway garden is the City of Bath pavilion, complete with hot springs. In front Messrs. Blackmore and Langdon have been showing stately delphiniums, phlox, pansies and their well known tuberous-rooted begonias.

A large area has been laid out to the best advantage by Messrs. Wallace and Co. The several designs are so successful that there are gardens for almost every taste, and yet the whole is harmonious. A delightful rock garden, with waterfall dropping to an attractively shaped pool, leads to an uncommon garden which may almost be described as being a series of very broad stone steps flanked by herbaceous borders, which have been in season throughout the whole period. South of the rock garden is an interesting shrubbery from which a path winds to a rose garden with a sunken pool and enclosed by a good yew hedge. Messrs. Lowe and Gibson have, near by, a small garden of gladioli and border carnations; while Mr. H. Yandell filled an uncommon garden with his violas.

Dianthus Allwoodii, new perpetual border and the true perpetual-flowering carnations are shown in their garden by Messrs. Allwood Brothers, where, amid pleasant surroundings, many visitors have enjoyed the charm and fragrance of these beautiful flowers. The value of the Allwoodii is now well known and appreciated, and in floriferousness is almost equalled by the new perpetual-border hybrids. These, at Wembley, embrace many charming shades of colour, several, at least, are deliciously fragrant and have been blooming continuously.

A magnificent dahlia garden is provided by Messrs. William Treseder, Limited. All the types are included, and while most of the blooms would grace the show bench the varieties are also of value for garden decoration. The first flowers appeared in May, and as the season advanced the blaze of colour strengthened until, even at the end of September, there is a magnificent display.

A handsome collection of hardy trees and shrubs is shown by Messrs. Fisher, Son and Sibray. Cupressus Lawsoniana lutea, Retinospora pisifera aurea, R. obtusa Crippsii, Sciadopitys verticillata,

Digitized by Google

Picea Omorica, Abies concolor, Cedrus atlantica and Podocarpus Koreana are the names of only a few of the splendid conifers to be seen. There are also equally good specimens of hollies, skimmia, Grisselina littoralis, ivies and dimorphanthus mandschuricus aurea variegata.

A well conceived rockery, flower borders and several of his quite small sunken gardens are exhibited by Mr. Ernest Dixon. These are all appropriately planted with, as the notice board states, ordinary stock from the nursery, and with a satisfactory result.

Fruit trees and bushes of all types are well represented by Messrs. Seabrook and Sons, Messrs. Laxton Brothers, Messrs. T. Rivers and Sons and Messrs. S. Spooner and Sons. The first-named has two "commercial plantations" of cordons, bush and standards on such stocks as Paradise and Jaune de Metz for the apples, and quince for the pears. Messrs. Laxton have made theirs a fruit garden beautiful, and it contains perfectly trained peaches, plums, apples and gooseberries, among other fruits. Espalier trees are especially typical, among the good standard and bush trees shown by Messrs. T. Rivers and Sons.

Orchids of great value in the scheme of glasshouse work are shown by Messrs. Charlesworth and Co. in specially built glasshouses. Further mention of these will be made when we remark on the plants and flowers under cover.

CORRESPONDENCE

GALLS ON THE LEAVES OF THE LIME.

SIR,—The enclosed illustration may prove of interest to readers of THE GARDEN, as it represents what are popularly known as

BLISTERS POPULARLY KNOWN AS "NAIL GALLS" STUDDING THE LEAVES OF THE LIME.

"nail galls" on the leaves of the lime tree, Tilia europæa. These galls are caused by a very interesting species of gall mite known as Eriophyes tiliæ, inasmuch as they were first considered to be a special vegetable formation accruing from the action of animal life. Later on it was recognised that the growths were due to the stimulus of one of these small mites. These growths are not true galls, but pseudo galls. The former are the outcome of the damage created by true gall-forming insects. These pseudo galls are of a bright reddish colour, small in size and tapering in shape. They are always to be found on the upper surface of the leaf. They do not cause a great deal of damage and to a slight extent beautify the tree.—C. LACEY, *Wimbledon, S.W.*

RHODODENDRON LODERI.

SIR,—The note under the illustration of this rhododendron on page 657 may prove unduly discouraging to those who wish to grow it. The statement that "it survives in the north but only grows to its full luxuriance in the south and west of England" is not in accordance with fact. It is hardier than R. Griffithianum (Aucklandi), which is one of the parents of this fine hybrid, and it flourishes luxuriantly on the west coast of Scotland as far north as Ross-shire, provided that it is grown in half-shade and given adequate shelter from wind.—HERBERT MAXWELL, *Monreith.*

SIR,—In your issue of September 27th there is a photograph of Rhododendron Loderi which is described as "surviving" in the North.

At Dawyck in Peeblesshire Mr. F. R. S. Balfour showed me this summer a number of plants of this hybrid 6ft. or more in height and in full flower. The blooms were large and numerous and their scent carried to a considerable distance. This was in a shady glen, where the plants are out of reach of the morning sun. Dawyck is a cold place and faces north. Gardeners cannot be too often reminded that the range of the more "delicate" Himalayan and Chinese rhododendrons is less limited by extremes of cold than by variations of temperature. It follows that, next to the frostless areas near the sea, the safest homes for them will be found where the conditions are such as to discourage too prolonged in autumn or premature growth in spring.—JOHN STIRLING MAXWELL, *Glasgow*

MICHAELMAS DAISIES.

SIR,—With reference to Mr. Jacob's article on Michaelmas daisies (page 675), I notice that he is asking for advice as to the best method of staking them. Mr. Dickson, head-gardener to the late Duchess of Bedford at Chenies, used to put in ordinary pea stakes when the plants were growing, and as the plants grew they quite covered up the stakes, which held the plants well together.—E. G. Q.

ORNITHOGALUM THYRSOIDES.

SIR,—I note that in a recent issue of THE GARDEN a correspondent speaks of Ornithogalum thyrsoides and the difficulty of growing it. I received some seed four or five years ago from Johannesburg and sowed it in pots. It came up freely and in about three years flowered in the same pots and again this year flowered freely, though so thick in the pots that I feared it was too crowded to flower. It seems evergreen, as it has never died off for me to venture to transplant. The seed has ripened well this summer.—(Rev.) W. OSWALD WAIT, *Herefordshire.*

RANUNCULUS LIBANOTICUS.

SIR.—I think there is little doubt that the above specific name should really be R. asiaticus, under which name I have grown for many years a very beautiful spring-flowering scarlet single-flowered ranunculus. I rather think mine came from Messrs. R. Wallace and Co. It has spread freely, but not by seed—I have never seen one—but by underground stems, after the same manner as Tulipa saxatile; but, happily, these young plants flower in due course, which the tulip objects to doing. I rather think there is more than one form, for I have had one with a yellow reverse, not nearly as good a plant as the all scarlet and black one. With regard to Tulipa saxatile, I wish someone could give me a recipe to make this tulip flower. It spreads by the yard underground. The lifting of the bulbs and the drying of them are impossible where they are. All the same, the lovely foliage is a joy in spring, forming a carpet of polished green of a delightful tone. In another garden it is almost a "weed," but there it is a flowering one: Why?—C. M. B., *Isle of Wight.*

ASTER AMELLUS BEACON.

SIR.—Like other Michaelmas daisies in this district, Aster Amellus Beacon, a new variety, has been late of coming into flower. It is quite a good variety with large flowers, described—with, perhaps, a little of the exaggeration we sometimes find in catalogues—as glowing carmine. It is quite a bright flower, and will be valuable as an addition to an important class of starworts. It has, also, a good erect habit, and here it requires no staking. It is rather more than a foot height.—S. A., *Lockerbie.*

THE TREATMENT OF CARNATIONS

THE present time is an important one for the carnation grower. For outdoor carnations all layering should be completed, and in the case of the hardy perpetual border carnations, also Dianthus Allwoodii, cuttings can still be inserted, in fact, these root better at this time than in the early summer. Sharp sand is undoubtedly the best medium, and a cold frame where they are shaded from the strongest sun is practically all that is necessary. Autumn planting for all races of hardy carnations is becoming more and more popular, and providing there is a free drainage, undoubtedly the best results are obtained. The ideal position is a sunny one. A carnation abhors shade, and if there is any doubt about the drainage it is much better to raise the beds by adding additional soil. All carnations must have a certain amount of lime in the soil—in the case of heavy soils, freshly burnt lime is best; in the medium soil, old mortar rubble; but in a very light soil, pulverised chalk should have preference. Manure must only be added in small quantities—in heavy soils, horse manure; and in light soil, cow manure are best. This can be dug in immediately, then the beds will be ready to receive the young stock. No leaf-mould should be given to carnations at any time.

Too many hardy carnations are spoilt through deep planting. No more of the stem should be buried than is necessary, and if it is possible to plant without burying any of the stem at all, undoubtedly the plants prosper better.

Of the newer kinds of border carnations Saracen, with its French grey ground striped cream and crimson; Paula, white, pencilled red; and Sheila Gibson, a delightful shade of apricot, are best.

In the new hardy perpetual border carnation section, Sussex Lass (rose pink), Sussex Earl (deep heliotrope), Sussex Salmon and Sussex Empress (clear pink) are undoubtedly great advances; while in the Dianthus Allwoodii section, Arthur, as we saw at the Chelsea Show, is simply marvellous, with its red maroon shading; Elizabeth (clear salmon) and Beatrice (orange red) are wonderful varieties.

In the perpetual-flowering carnations, with this wet, cold season, those who are growing their plants out of doors will be well advised to bring them into the greenhouse as soon as possible, and if the plants have made very good growth, and they are only in 6in. or 7in. pots, it would be best to pot them on into larger pots, sooner than have the roots cramped and starved through the winter months. I suppose there never was a season when perpetual-flowering carnations made more growth, but with this growth, which is naturally very soft, thrip in many parts of the country have played havoc, and the use of an insecticide spray which is free from any deposit is best. If the insecticide spray has any deposit it does considerable harm by choking the pores of the leaf. It is folly to allow your plants to become starved through want of feeding, and then, if they are showing signs of this, to feed them to excess; feeding with some slow-acting organic food must be followed out gradually, according to directions, through the entire season. Split calyces in the autumn are invariably the cause of starvation followed by improper feeding; but your old perpetual-flowering carnations, if generously treated, produce tremendous quantities of bloom during the second year; but it should be remembered that for stock purposes these are not nearly so valuable as the younger plants—in fact, the leading growers in the country are no longer propagating from the older plants, but selecting the best of the newer stock for propagating purposes. Staking carnations should be carried out with wire circular plant supports, the result being that the plants grow much more naturally and also have more air space than if they are tied with raffia.

A BEAUTIFUL AND EASILY GROWN ANNUAL

ALTHOUGH an old and very ornamental plant, introduced as long ago as 1839, Impatiens Roylei, also called I. glandulifera, a native of India, is rarely found in gardens nowadays. It is a strong grower of stately appearance, attaining a height of 4ft. to 6ft., according to soil and position. Being a member of the "touch-me-not" group of plants, it sends its seeds in all directions at maturity, by means of the bursting pods. These seeds lie in the ground all winter and begin germination in very early spring. Owing to this fact, it is unnecessary to trouble about propagation once the plant has been established at one spot. All one has to do is to thin out the numerous seedlings, to transplant these if so desired, and to leave only one plant every three or four feet, which is a necessary distance if fine plants are wanted. This method of propagation is by far the best. Seeds which have been dried and stored germinate, as a rule, rather badly, and no doubt the rarity of the plant in gardens can be traced to this fact.

IMPATIENS ROYLEI ALBA, WITH ITS BEAUTIFUL WHITE FLOWERS SO EFFECTIVE WHEN GROWN IN MASSES.

Impatiens Roylei is of a greedy nature. It requires a very rich soil and a liberal amount of moisture. The position best suited to it is a shady or half-shady corner, although it also makes fine plants in open situations. In this last case, the growth is shorter and sturdier. Enormous plants which will strike anybody who sees them can be obtained with the greatest ease by giving specially selected specimens plenty of air, manure and moisture.

The thick, succulent stems of Impatiens Roylei are hollow and well developed at the base. They show numerous adventitious roots near their base which develop readily in favourable conditions. The nodes are conspicuously swollen and the internodes ribbed. All the tissues of the plant are of a noticeable pink colour.

The flowers are borne liberally all through the summer and autumn in large terminal inflorescences of graceful habit. They are pink with scattered reddish dots on the lower petal, ¾in. to 1¼ins. wide, 2ins. long, and of most peculiar build. The upper petal is bi-labiate and mucronate, the lateral ones most irregular and thrust forward, while the lower one is large and conspicuously ventricose, with a short spur. On the whole, the flowers recall vaguely the form of some orchids.

Besides the type form, a variety, alba, is also cultivated. It has the same characteristics, save the colour, which is pure white, and the absence of pigment in the tissues that makes it quite distinct from the earliest stage of vegetation. It is a very effective form, especially when grown in masses.

Both these showy balsams deserve the best attention and can be cultivated with great advantage. Their easy manner of regeneration makes them practically perennial plants. One of the best ways to utilise them probably is to grow them in odd semi-shady positions, where there is a sufficient supply of air and moisture—for instance, among trees and shrubs not too thickly planted. C. L.

NOTES FROM CONTRIBUTORS

THE PRAIRIE BLAZING STAR OR BUTTON ROOT.

(LACINARIA OR LIATRIS PYCNOSTACHYA.)

IT was rather an agreeable surprise to see in several private garden exhibits of hardy flowers at a recent show a number of good spikes of this showy plant, which has been grown more or less successfully in the south-west of Scotland for a good many years. It has a rather dubious reputation in this part of the country, where the humidity is, to say the least of it, especially in a season such as this, not "below the average," and this year is far above it. I have never been able to diagnose with any confidence the precise cause of the loss of so many plants of the liatrises in our gardens, but I know that many have given up trying to suit these showy flowers, often justly called Gay Feathers. It was, therefore, a pleasure to see so many exhibits of L. pycnostachya at this one show. It is one of the best of these liatrises known to me, and I have seen a good many of the sixteen species said to exist, of which only a few are in cultivation. Certainly I know of none superior in effect to L. pycnostachya in gardens. Its tall 3ft. or 4ft. spikes with their handsome feathery-looking flowers at the summit form a striking object in the border in August, even earlier in some places. It is true that the colour of the flowers—approaching pure magenta—does not find favour with many, but it can be modified by association with other flowers or with plenty of greenery. L. pycnostachya is a prairie plant of the United States, and it is distributed over a very wide region, and I have been wondering if the loss of some of the plants may not have been due to their being collected in the more southerly habitats, say, from Texas. It ought to have a dry, light soil, so far as I have been able to decide, with an open, sunny situation. It appears to be hardy as a rule, but, as already mentioned, losses have been very frequent. It will be noted that I have named this plant "Lacinaria" or "Liatris" pycnostachya. The latter is the name almost universally adopted in this country, but I observed a little while ago that Britton and Brown adopt the title of lacinaria, apparently preferring Hill's name of 1762 to the generally accepted one of 1791, which is likely to be preferred by British growers.—S. ARNOTT, *Dumfries.*

THE CHATHAM ISLAND FORGET-ME NOT.

MANY have tried but few have succeeded in growing this magnificent plant successfully, but here are a few pointers that may prove helpful and lead to success for others who have not done well with the plant. To begin with, it is not hardy except in the most favoured parts of the country and—in addition to giving it your warmest and most favoured position—some measure of protection should be provided for the plants during the worst of the winter months. Secondly, it has a tremendous love for a top-dressing of seaweed in autumn, a dressing that may with advantage be allowed to lie upon the ground until it is completely rotted away and which, by reason of the salt it contains, no doubt does much towards protecting the roots from frost during the winter months. Never, if avoidable, disturb the roots and rely upon seeds for raising your new plants. During spring and summer full supplies of water should be afforded, but in winter the plant should be protected from excessive wet by means of a bell-glass dropped over the crowns. Treated thus I have seen this and its white variety attain a height of fully 2ft., with bold and handsome glossy green leaves and dense masses of the glorious blue and white flowers that were a joy to behold in April and May. In the type the centre of the flower is blue margined with white, but there is also—in Myosotidium nobile alba—a pure white form, although this is much scarcer.—SANDSTONE, *Hampshire.*

A NEW HYBRID HEMEROCALLIS.

I READ with particular interest the note in your issue of August 2nd on Mr. Perry's new hybrid Hemerocallis Lady Hesketh, which received an award of merit, R.H.S., on July 22nd. I have just produced a new

AN AMERICAN HYBRID HEMEROCALLIS OF SUPERIOR FORM.

hybrid which I have named Hyperion, which I believe surpasses any other in practically every feature, and from which I am hoping to develop a new race of larger and better formed hemerocallis. In view of the recent appearance of Mr. Perry's new variety you may be interested to publish a picture of H. hybrida Hyperion, which is a cross between Sir Michael Foster and Florham. The illustration shows very well the superior form of Hyperion both as regards the individual petal and the flower as a whole. Hyperion is 4oins. tall with stout, rigid stems; its form, as will be noticed, is superb. In size it is unequalled, as it is over 5ins. across and some flowers are even 6ins. wide. It is of heavier substance than any other and its texture is of the best. Its colour is also of the brightest and clearest quality, pure lemon yellow, according to Ridgeway. When I first began to subscribe to THE GARDEN I preserved only clippings, but I ultimately found its columns so full of material that I now preserve the issue intact. I am an amateur intensely interested in the future development of an intelligent horticulture in America as exists in England.—FRANKLIN B. MEAD, *Indiana, U.S.A.*

ANCHUSA ITALICA LISSADELL.

I WONDER if any readers of THE GARDEN have had any experience of the above variety of anchusa. I purchased seed of it in May, 1923, and by some mischance the seed-pan after the seedlings were well up was put in some out of the way corner and turned up again in the autumn, after the foliage had died down. As there appeared to be roots of some kind in the pan, I decided to give them a chance, so put the pan into a cold frame until the spring. In due course about seven small crowns pushed up their rosettes of leaves, so I just made a hole in the border and without disturbing the soil in the pan planted them as one clump. The young plants grew quickly and commenced flowering early in July. So far as I can see, the colour differs but little from A. italica Dropmore, but the habit of the plant is superior. Two plants in the clump have attained the height of 7ft. 6ins., and are now just as full of bloom as they were six weeks ago. Although growing to such a height, the plants have never been staked. They have made perfect pyramids of bloom and have been the admiration of hundreds of visitors. The catalogue description is as follows: "A beautiful border plant, producing large flowers of a clear gentian blue. H.P. Height 5ft." It seems to me a remarkable thing this variety of anchusa should attain the height of nearly 8ft. without a support, while in the same border A. italica Dropmore and Opal, in spite of every care, are beaten down with wind and rain.—F. C. KING, *Milnthorpe.*

THREE FIRST CLASS NEW APPLES.

NOT every new variety of apple that finds its way into commerce can claim to be tip-top in the best sense of such description, but the three varieties mentioned below can honestly make such a claim, in my opinion, notwithstanding the fact that one of the sorts has so far failed to gain the R.H.S. award of merit. This variety, Lord Lambourne, is one of Messrs. Laxton's new dessert apples, and is the result of crossing James Grieve with Worcester Pearmain, the latter parent contributing to the high colour and firmness of Lord Lambourne. Its good flavour and juiciness is, of course, obtained more directly from James Grieve. In size it is much akin to Worcester Pearmain, but it is somewhat flatter in shape than the latter. The yellow skin of Apple Lord Lambourne is nicely flushed with red, and its season for use is October and November.

An earlier variety of the same firm's raising is the Premier apple, which has gained the Royal Horticultural Society's award of merit. Its parents are Mr. Gladstone and Worcester Pearmain. The flavour is quite good and its colour is equal to a Worcester, which fact will make it a capital market sort and a probable rival of that old variety, especially as it ripens a week or so before Worcester Pearmain. The Premier is also a good cropping apple.

The third apple of these notes is quite a late variety, and one of the best—if not *the* best—yet raised by any firm, namely, Apple Laxton's Superb, a variety obtained by crossing Wyken Pippin and Cox's Orange Pippin. I have not eaten any apple I like better. The renowned Cox has at last a formidable rival in flavour and every respect, I am convinced, in Laxton's Superb. The fruit is slightly bigger than Cox, yellow of skin and strongly flushed red on the side most exposed. The flesh is white and of a delicious crispy sweetness; in short, the flavour is really first-class. Fruits will keep well into March easily. Its cropping quality is of the best and the variety is a strong, healthy grower. To any readers desiring to know of any new, thoroughly good varieties of apples I can honestly recommend the foregoing.—C. TURNER (gardener to Lady Ampthill).

SIMPLE GARDENING

TREE CARNATIONS.

THE tree or winter-flowering carnation now finds a place in the amateur cultivator's greenhouse. Although considerable skill is requierd to grow plants and flowers really well, the plants are very accommodating and economical to grow as regards daily attention and fire-heat. In one case I remember the boiler failing, and as the winter weather proved kindly the carnations were grown without artificial heat, and the cultivator said he thought the flowers were finer than in previous years with heat. Too much heat is bad for these plants, but a judicious use of it, coupled with careful ventilation and watering, also shading, will ensure the most satisfactory results. Propagation of young slips should receive attention from this month onward. I know how difficult many amateurs find the satisfactory rooting of certain varieties to be, notably that lovely crimson British Triumph. In the autumn I do not experience any trouble in the matter; in spring I do. During this month good sturdy slips, taken from half-way up the stem, should be inserted in a bed of coarse, washed sand on a thin layer of rotted leaf-soil in a box or cold frame placed outside behind a wall facing north. Slightly split the base of each cutting, insert 2ins. apart, water and close the frame. Early in January cuttings so treated will possess tufts of roots. I rarely find it necessary to water the cuttings a second time up to this date and stage.

POTTING YOUNG FERNS.

The re-potting and division—where the latter work is advisable—of old specimens are best done about the month of February; but, of course, where there are small ones in tiny pots, it is a different matter. I am sure that many readers of THE GARDEN have in past years possessed such plants and found them deteriorate by the time spring comes, lower fronds turning yellow or brown and becoming useless. The timely re-potting in October prevents the loss of the lower fronds and increases the strength of the new—the young fronds. Between October and January many new roots are made if the plants are properly treated. This is the correct treatment: The compost should consist of fibrous loam 1 part, leaf-soil 1 part, old mortar rubble, sand and silver sand, combined, 1 part. Plants now in thumb pots, 72's, should be shifted into large 60's—pots 3½ins. across. Hard potting is neither necessary nor advisable at this stage; but clean, dry pots and crocks are essential, and firming of the soil may be done with the aid of a stout plant label. If the greenhouse is a very dry one the re-potted ferns should be placed in shallow boxes—those about the depth of the 3½in. pots—on a thin layer of ashes, leaf-soil or coconut fibre. This position, in the coolest part of the structure, will ensure steady progress of the plants throughout the winter and spring months. Avoid over-watering, but be sure that the soil in the pots does not get dry. If the atmosphere of the house is naturally a moist one the open stage will prove a suitable position for the plants.

PROPAGATION OF EVERGREEN SHRUBS.

The propagation of shrubs from cuttings is a very interesting occupation. We possess, most likely, a few favourite shrubs and would like to increase them, if possible; this may be done if the slips

are properly selected, prepared and inserted. Shoots of the current year's growth are the best and should be cut off with a tiny heel of older wood attached as shown at No. 1. This cutting is shown placed in the prepared trench at No. 2. Moderately firm ground on the north side of a wall or fence is the best for the cuttings. A small trench is made and coarse sand freely scattered in the bottom for the base of the cutting to rest in, then a callus will form, followed by roots in due course. Other cuttings are prepared as shown at No. 3, being cut off immediately below a joint. The leaves from that joint must be cut off. Make the soil very firm around the inserted cuttings, especially after frosts have occurred. The following year the cuttings will be tiny plants as shown at No. 4, but should not be disturbed too soon.

PLANTING RASPBERRIES AND LOGANBERRIES.

Although the raspberry is very extensively grown and not really difficult to cultivate there is much misunderstanding of the plants in regard to general treatment. The canes possess masses of fibrous roots which permeate the surface portion of the soil, and undue surface disturbance of the soil should be avoided. A firm rooting medium is also essential. The planting season is now at hand, and the work should be commenced directly the soil is in good condition; preparation should be thorough. Dig deeply, break up the sub-soil, add well rotted manure, take out the roots of weeds, select canes of medium strength not weaklings nor thick ones with few roots. Plant in rows 5ft. apart and 7in. from plant to plant; in clumps, 3in. each plant and 4ft. from clump to clump. Cut down the canes to within 1ft. of the roots; firm the soil and apply a surface mulch. Provide the necessary supports for the new canes next year. Loganberries should be treated similarly, but three times as much space should be allowed for the extension of the growth. Furthermore, these plants are splendid for training on rustic fences and posts, for forming a screen between the flower and the vegetable garden.

THE LAWN.

The lawn, and grass edgings to paths and borders, should be attended to in good time. We cannot afford to neglect them if we wish to have a really beautiful and attractive garden. So many amateur cultivators place their faith entirely in a surface-dressing of manure. I may shock these when I advise them to avoid such manures for lawns and reserve it for the fruit and vegetable garden. I have known a whole lawn have to be returfed through the excessive use of rotten farmyard manure in winter. Such manures often contain the seeds of strong-growing weeds, too. A mossy lawn should be thoroughly raked with a sharp-toothed iron rake now. Then, for a stimulant apply 1 peck of wood ashes, half a bushel of fine-ground lime and 3lb. of coarse bonemeal or finely ground bones per square rod of lawn. The ingredients, being well mixed, should be evenly applied but not brushed in; they will penetrate soon enough, and the small bones will be helpful all through next summer. Following this application, give a good dressing of sound loam passed through a 1in. mesh sieve.

GEORGE GARNER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Rhubarb.—The leaves and stems have died off, and now these should be collected with all the weeds and the bed made clean and tidy. The surface may be lightly pricked over with a fork, and then a mulching of partly decayed manure may be given. Where rhubarb is forced a few of the roots ought to be lifted and laid aside in a cool position well exposed to the weather until needed for forcing. Underneath the stage of a greenhouse or a cellar is well adapted for growing early rhubarb.

Dwarf Beans.—Late dwarf beans can be protected from slight frosts by placing lights over them at night or fixing a wooden framework on which could be arranged a few mats. A batch in full bearing is well worth the trouble, which will prolong the supply. Late marrows ought also to be protected from frosts.

FRUITS UNDER GLASS.

Strawberries.—Plants that were potted some weeks ago have filled their receptacles with roots, and now they may be fed with liquid manure at alternate waterings. Clear soot water is an excellent stimulant, it is also detrimental to various pests, while the foliage assumes that fine green colour so much desired by cultivators. All runners should be removed as they appear, and it ought to be borne in mind that one healthy single crown will give better results than two or three weak ones. The plants should occupy a place on a firm ash base, and be prevented from rooting through the bottom of the pots by giving the latter an occasional twist. Owing to the heavy rainfall the plants have been stood on strips of wood and plenty of space allowed between the pots to give the plants all the air and sunshine possible.

Pot Trees that have borne fruit may be re-potted or top-dressed at this season, and regarding their culture much depends upon this work, for unless the roots are healthy the size and quality of the fruits will suffer. Annual re-potting may not be necessary, and in such instances top-dressing will suffice. Clean pots and ample drainage are essential. The rooting medium should consist of good turfy loam with a moderate sprinkling of old mortar rubble and a 5in. potful of bonemeal to every bushel of the compost. Before re-potting allow the trees to become slightly dry at the roots, and the potting soil should be neither too dry nor too wet. Turn the plants out of their pots, and where the roots are closely matted together a receptacle one size larger will be needed. In other cases it will be possible to reduce the ball, and coarse-growing roots may be cut away, when the same size pot will suffice. Ram the soil as the work of re-potting proceeds, and allow enough space at the top for watering purposes. When top-dressing, remove as much of the top soil as possible with a pointed stick and replace it with fresh material. Then take the trees to the reserve ground and plunge the pots to their rims in ashes. See that the trees are not disturbed by wind and storms.

THE FLOWER GARDEN.

Carnations.—The layers are well supplied with roots, and where it is usual they can be planted in their flowering quarters or potted up and placed in cold frames for the winter. Give the ground a dressing of old mortar rubble and make the soil firm around the roots. If in frames, admit plenty of air, and remove dead leaves as they appear.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Brussels Sprouts.—Owing to the wet and somewhat sunless summer, plants have made a good deal of leafage and thereby have become rather crowded. A few of the lower leaves should, therefore, be cut away from each plant. This will not only facilitate getting among the plants for pulling the sprouts when ready, but will also allow light and air to reach the stems.

Celery.—It is time now to make a start with the further tying and earthing of the plants so that they will be quite safe should a spell of severe weather come.

Peas.—The later sown varieties have suffered from the bad weather, so much so that portions of the pods rotted before they were half matured; while more advanced pods seemed very slow at filling up. Spent straw should be collected when dry and set on fire; this material need not be taken away, but simply piled in a heap and burned on the ground, while the valuable ash should be spread over and dug into the soil.

THE FLOWER GARDEN.

Bedding Begonias.—When these plants are lifted from the beds it is usual to place them in cutting boxes with quite a quantity of soil clinging to the roots. This soil should be fairly dry now and should be cleared away from underneath and around the corms. Dead and decaying leaves and stems should be taken off at the same time, so that nothing is left about likely to cause damp. It is usual to keep the corms in cutting boxes, especially if the varieties are to be kept separate. The boxes should then be placed in a cool, airy, but frost-proof shed.

Carnations.—Where plants suffer if left out of doors in the winter, it will be safer to lift the rooted layers now and set them a few inches distant from each other in a cold frame. These plants should be transferred to prepared beds in March or April of next year.

Echeverias.—These somewhat old-fashioned plants are very useful for bedding purposes, and really they are effective either in or out of flower, but certainly more so when their graceful spikes are adorned with dainty reddish yellow flowers. Plants should be lifted now, and where younger ones have grown around the older plants they should be detached and set by themselves in one section of the frame. The older plants should also be kept together, and set so that the leaves just touch.

Roses.—Where cuttings of climbing or Wichuraiana roses were inserted last autumn, they should be in good condition now for transplanting to their permanent positions at arbours, fences, pergolas or poles.

THE HARDY FRUIT GARDEN.

Root Pruning.—Established trees which make a great deal of strong growths and bear little or no fruit should receive attention now in the way of root pruning. The usual mode of procedure is to dig out a trench around one-half of the tree, keeping 2ft. or more from the trunk according to the size of the tree. All large roots encountered should be severed, and it may be found necessary sometimes to go partly underneath the tree. On no account add rich manure or fresh soil when filling in the excavations, but simply put back the soil that was taken out. When feeding does take place, do so just underneath the surface soil, or on the surface. The remaining half of the tree or trees should be root-pruned the following year.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Chrysanthemum Parthenium var. fl. pl.—This double-flowered variety, although hardy, is an excellent plant for the cool greenhouse, and it is surprising it is not more frequently grown for this and decorative purposes generally, as it is very useful for cutting and making up. If cuttings are inserted at this time, good plants will be obtained for flowering next summer. The cuttings should be pulled off from the base of the old plants, and as they usually show signs of roots, they may be dibbled singly into small pots, afterwards standing them in a cold frame, where they should be given plenty of air at all times, as the plant is really hardy. Potted on as they require it until they are in 6in. or 7in. pots, they should be fine plants for next year.

Hydrangeas.—Some time this month large specimen plants that have been standing outdoors should be stored in a frost-proof building. A cold greenhouse is, of course, the most suitable place if the room can be spared. Failing this a shed with some top light will answer the purpose, or even a shed with an open front where canvas or mats can be hung up during severe spells of frost. Large specimens should be examined several times during the winter in case they need water, for if allowed to become too dry for any length of time they are apt to suffer. Young stock of hydrangeas should be stored in cold frames or in a cold greenhouse. Plants in frames may have the lights removed on every favourable occasion, taking care, however, that they are not exposed to too much frost, as the flower-buds may thus get injured. Young plants propagated this year will not stand drying off like large specimens if standing on a damp bottom. However, it is unlikely that they will require water until they are started into growth early in the New Year.

Crinums and Agapanthus.—Failing accommodation in a cool greenhouse these may be safely stored in sheds that are fairly frost-proof. This also applies to quite a number of plants that should be got under cover this month.

Roses for Pots.—Where stocks of roses are grown for pot work, they should, towards the end of the month, be lifted and placed in suitable-sized pots. The dwarf polyantha varieties are very useful for pot work, and plants raised from cuttings put in outdoors early last November are now ready for lifting and potting up. The stronger-growing varieties will require 6in. pots, while smaller plants are very useful in 48-sized pots. Some of the long roots should be shortened back and the plants potted firmly in a compost of good turfy loam, adding a 6in. potful of fine bone meal to every bushel of soil. After potting, the pots should be plunged to the rim in ashes in an open position outdoors. Plants treated in this way can be used for forcing early next year. They can be grown on for the second year, when they make good specimens. Stock is so easily raised by means of cuttings that it is not worth growing the same plants for more than two years.

Campanula Medium (Canterbury Bells) are very useful for the conservatory, large well grown specimens being very handsome. For this purpose plants should, some time during the month, be lifted and placed in pots. Large well grown plants may require 6in. pots, giving them a shift early next year into 8in. or 10in. pots. After potting at this time they may be stood in cold frames, where they should get plenty of air, removing the lights on every favourable occasion.

BOOK REVIEWS

THE manifold interest in agriculture is evidenced almost every other day by articles and books appearing on the subject and yet another falls to be added to the already long list. The present volume, "Soils and Crops," by John S. Gehrs, B.S., M.S., published by the Macmillan Co., price 6s. 6d., deals with conditions in America, although the production of crops and the methods employed in other countries of the world have been briefly considered. We agree with the author in that he is wise to take up an international view-point, the reader gaining thereby a wider and better appreciation of the subject. Much new material is incorporated in the little manual, which should prove exceptionally useful both to the teacher and student. All the main facts and principles of agriculture are treated concisely, yet nothing essential is missed out. The book gains much in being divided into three separate sections—the first treating of soils, wherein is discussed their texture and composition, with a few chapters on manures. Section two deals mainly with crops, their production and marketing. The last section is devoted to horticulture, embracing vegetable gardening, fruit-growing, plant propagation, and being completed with a short chapter on injurious insects and methods of control. The author makes it clear that much more work remains to be done, and that our knowledge of the soil and the crops is by no means adequate. The book includes a wide range of agricultural topics, being adapted for a large area, and is written in a simple and lucid yet instructive style suited for young students of the subject. Useful hints and exercises are given throughout its pages to teachers. It is well and clearly printed and copiously illustrated by means of numerous diagrams and half-tone blocks, while it shows every care in compilation. G. C. T.

THERE are few English gardens in which the rose does not find a conspicuous place and there are not a few volumes which speak both of the innumerable varieties from which to make a selection and of the methods by which to obtain success in their culture. But the book before us, "The Roses of Britain," by Lieut-Colonel A. H. Wolley-Dod (Taylor and Francis, London, 1924; price 5s.) is not one of these. Its scope is perhaps best indicated in the words of its sub-title, which runs as follows: "Detailed descriptions of the wild roses known to grow in the British Islands, with notes on their peculiarities and affinities, and on their comital distribution." The author has devoted twenty years to his subject, and the careful systematic account he gives of a very difficult genus of plants as represented in the native flora of this country should be of interest to those who may wish full descriptions of the wild roses from which so many favourite garden varieties have been derived. Definitions are first given of the four sections of the genus, Synstylæ, Stylosæ, Spinosissimæ and Caninæ, into which all our native roses are arranged by the systematic botanist. Thereafter follows the detailed descriptions of 17 species, 110 varieties and 48 forms, besides a considerable number of natural hybrids. The widely distributed Ayrshire rose, R. arvensis, is the first species to be dealt with. A full account is likewise given of the Scotch rose, R. spinosissima, the forerunner of many garden forms and a species which hybridises readily. But the descriptions of the dog rose and its allies, belonging to the section Caninæ, occupy by far the greater part of the book. Such species as R. canina, R. pomifera, R. tomentosa and R. rubiginosa, all of which have been of value in the production of attractive garden varieties, are described in great detail.

It is no easy matter to identify roses, and to the beginner using this book it would have been helpful if the author had supplied a key by means of which the different species could have been determined. The book rather tends towards that type written by a specialist for the benefit of specialists. The number of hybrids described goes to show that crossing must occur not infrequently in Nature and is not left entirely to the hands of the practised cultivator working in the precincts of his nursery or garden.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Asters Diseased (Miss A. H. M.).—The plants are affected by the black rot fungus. Although the roots may be healthy, or appear to be so, now, they are not. The fungus spreads upwards from the collar of the plant-stem or stalk. There is no cure in this case, and the best thing to do is carefully to remove the plants with roots and any soil adhering to them and burn all. Dress the soil in the bed with fresh lime, and do not plant anything there before next spring.

Plants for Herbaceous Border and Treatment of Heath Plant (D. M.).—It was quite correct treatment to mix the organic manure with the lower soil of the border, and bone-meal may be incorporated in the top portion. The superphosphate is best applied to the plants when the latter begin to grow freely. The sweet peas, Canterbury bells and delphiniums require more space than you are allowing them, so the width of the border should be 8ft. to permit of five rows of plants, including the Brompton stocks and violas having sufficient room to develop fully without undue crowding. As the heath plant is now doing well, apply clear water only; manures would probably kill the roots. Very weak stimulants should be applied when new growth begins after the flowering stage.

Dwarf Roses for Bedding (S. S. M. E.).—We feel that the following will be good varieties for your purpose: Florence Forrester, white tinged with lemon; Mrs. Elisha Hicks, blush pink; Mrs. W. J. Grant, pink; Lilian Moore, Indian yellow; Christine, Sovereign, rich yellow; Mrs. C. E. Shea, rosy scarlet; Lieut. Chauré, crimson; Colonel Oswald Fitzgerald, crimson; and Château de Clos Vougeot, dark crimson. We are pleased to hear that you propose to plant separate varieties in each of the beds, and would recommend that, as you are adding chopped loam, the soil is made quite firm before the planting is done. For the woodland planting, in addition to the varieties already selected we recommend Grüs an Teplitz, scarlet-crimson; Conrad F. Meyer, silvery rose; Moonlight, lemon white; Zéphirine Drouhin, bright carmine; Tea Rambler, coppery pink; and Gardenia, bright yellow.

Sowing Broom Seeds: Cutting Back Old Yews (Mrs. A. S.).—At a distance of a few feet apart small spaces should be cleared of weeds and foreign matter, then seeds of broom may be sown with every prospect of success. A few plants of double-flowered gorse would add to the effect. Broom (Cytisus) Andreanus is a very charming variety. If the old yews were cut down to within 2ft. of the ground they would probably die. Only the young shoots of these trees should be freely cut, at least once a year.

THE GREENHOUSE.

Treatment of Begonia (W. C.).—Begonia martiana grandiflora is a warm-house variety and is readily increased by tubers. In our correspondent's case the intermediate structure will be quite suitable.

Treatment of Liliums (H. J. T.).—All lilium bulbs are impatient of exposure to air. Bulbs purchased are always surrounded by moisture-conserving material and should be potted forthwith. The small stem-bulbs and off-sets from the parent bulbs that you refer to should be potted at once and then retained in a cold frame safe from frost till new growth begins.

Plants for a Cool Greenhouse (M.).—For spring and summer flowering the following would prove very satisfactory: Bulbs in variety, especially narcissi, Agapanthus umbellatus, azaleas, calceolarias, deutzias, fuchsias, hydrangeas, kalosanthes, marguerites, zonal pelargoniums, petunias, tuberous begonias. For autumn and winter flowering: Early bulbs and chrysanthemums which have been grown outdoors in pots during the summer. These, if well selected, would flower from October to Christmas. Echeveria retusa (in mild winters), Eupatorium riparium, zonal pelargoniums and primulas, especially Primula malacoides. A selection from these plants would result in flowers being available all the year round without the aid of artificial heat.

KITCHEN GARDEN.

Tomatoes not Ripening Satisfactorily (A. W. C.).—The plants needed more potash in the soil. Lack of this, coupled with the cold, sunless season, has caused many fruits to finish badly. It may not occur next year. Add 1 peck of dry wood-ashes to 10 pecks of compost next season when mixing the compost for the plants to fruit in.

Kidney Beans and Other Vegetables Unsatisfactory (E. G. G.).—You have evidently, treated the various crops well; but the past summer months have not been quite normal as regards weather, and have been favourable to insect life generally. Kidney beans require heat and moisture; they have had an excess of cold moisture, and not much heat from the sun. Many flowers have proved abortive, owing to cold preventing pollination. No doubt caterpillars have eaten many leaves of the vegetables. Apply lime now, or as soon as the soil is dug, at the rate of 6 oz. per square yard, leaving it on the surface till February. Bone-meal is good for the crops. Do not over-manure.

MISCELLANEOUS.

Various Questions (R. W., Stirling).—The daffodil bulbs will not bloom very satisfactorily next year after such drastic treatment, but they may do so in 1926 if the foliage next year is allowed to fade naturally. If expected to bloom year after year, all such bulbs must be left in the ground to mature their foliage. If the roses Golden Emblem and Betty Uprichard are planted in well worked and properly drained soil they will thrive, if it is of a clayey nature. The following kinds of shrubs should thrive round the bungalow: Laurustinus, Andromeda floribunda, guelder rose, deutzia, Hibiscus syriacus, lilacs, Pyrus japonica, philadelphus, rhododendrons, azaleas, flowering currants, Weigelia rosea, spiræas in variety, berberises, arbutus, veronicas, buddleias and jasmine.

BLACKMORE & LANGDON'S DELPHINIUMS

Awarded R.H.S. GOLD MEDAL on JULY 8th, 1924.

Have received the highest Honours at all the principal Exhibitions. These should be planted at once for effect next season. We hold a most complete collection of splendid varieties, most of which have been raised at our nurseries, and have pleasure in offering

Collections of Twelve Choice named varieties at **15/-, 22/-, 30/-, 42/-** & **65/- per doz.**
Also Strong Seedling Roots - - - at **10/-** and **15/-** per doz.

The varieties "**Blue Boy,**" "**Millicent Blackmore**" and "**George Cochrane**" are included in the Collection at **65/-**

BLACKMORE & LANGDON'S CYCLAMEN

NOTHING CAN EXCEL THESE FOR A WINTER DISPLAY.

Grand Plants in 5in. pots, coming into flower in September, named varieties, at **25/-** and **30/-** per doz.

BLACKMORE & LANGDON, Bath

Specialities of THE BARNHAM NURSERIES LTD.

THESE ARE THE LARGEST NURSERIES ON THE SOUTH COAST AND CONTAIN IMMENSE STOCKS OF WELL GROWN TREES AND PLANTS IN GREAT VARIETY.

THE FOLLOWING ARE GROWN IN ESPECIALLY LARGE QUANTITIES:

FRUIT TREES. A magnificent stock of hardy, healthy, well-rooted trees in all forms required by Amateurs or Market Fruit Growers. *We can supply in dozen to 10,000 lots.*

ROSES. A fine lot of dwarfs, climbers, or standards in the finest varieties.

ORNAMENTAL TREES & SHRUBS. This section comprises a great variety of plants suitable for Seaside planting, including a large stock of **CUPRESSUS MACROCARPA,** the popular and fast-growing evergreen for shelter hedges or specimens.

Other hedge plants include Laurels, Yews, Privet, Quick, Hornbeam, Beech, Thuya Lobbii, etc.

HARDY PERENNIALS & ALPINES. A large stock of hardy, robust plants in choice variety. *For present planting we have a fine lot of Wallflowers, Forget-me-nots, Polyanthuses, Canterbury Bells, Violets, Pansies, etc.*

HARDY CLIMBERS in pots. A good collection of all popular kinds which can be planted successfully at any time.

We invite inspection at any time, and are pleased to book orders to be reserved until required.

Names of Plants.—(H. M.).—1, Rudbeckia speciosa; 2, R. laciniata Golden Glow. ——(Rydal).—Lavender cotton, Santolina chamæcyparissus, easy to grow from cuttings inserted now.——(H. G. S.).—Rubus flagelliformis.——(F. S. G.).—Phragmites communis, "Spire Weed."——(L. J. G.).—Atriplex hortensis rubra, "Mountain Spinach."

Names of Fruit.—(E. C. P.).—We think the apple is Bismarck—though the sample is rather a poor one and we cannot be quite certain about this. Bismarck is a good cooker and should keep until February. Any nurseryman could supply trees of this popular apple.——(W. W.).—(1) Astrachan Red, in season in August; (2) Worcester Pearmain, in season in September and early October. The transplanting should do the trees good. ——(I. C.).—(1) Worcester Pearmain, (2) Peasgood's Nonsuch, (3) The Houblon, (4) Kerry Pippin.——(H. M.).—(1) Probably Rambour Papaleau, we cannot be quite sure about this as only one fruit was sent and that not yet mature; (2) Worcester Pearmain; (3) Charles Ross.

National Potato Exhibition.—Arrangements have been made for the National Potato Exhibition to be held this year at the Junior Trading Hall, Leicester, on November 13th, 14th and 15th, in conjunction with the Annual Horticultural Exhibition of the County of Leicester Education Committee and the Leicester and Leicestershire Chrysanthemum Society. Copies of the prize list and any further particulars required may be obtained upon application to the Organising Secretary, Mr. W. H. Morter, Cannon Hill Park, Birmingham.

Trial of Roses at Wisley.—The Director of the Royal Horticultural Society's Gardens reminds raisers of new roses of the trials that are in progress at Wisley. Raisers are invited to send six plants of each new variety for trial to reach him by the end of November. They will be planted with those already growing and with standard varieties for comparison, and judged by a committee of rose growers appointed for the purpose. The necessary entry forms can be obtained on application to him at R.H.S. Gardens, Wisley, Ripley, Surrey.

Sweet Pea Trials.—The secretary of the National Sweet Pea Society asks us to remind raisers that those who desire to include their novelties in the 1925 trials, which are to be held at the Syon House Gardens, Brentford, should forward the seeds at an early date, addressed to Mr. A. C. Bartlett, 318, Kew Road, Kew.

British Florists' Federation.—At a meeting of the Market Floral Committee of the British Florists' Federation, held at Monro's Salerooms, Tavistock Street, Covent Garden, on Monday, September 22nd, Mr. W. E. Wallace presided, and chrysanthemums were the only subjects brought forward. The following awards were made: First-class Certificates.—To Chrysanthemum Mrs. Jack Pearson. A variety of reflexed Japanese type and very early flowering. Flowers have been placed on the market so early as the middle of July and the supply has continued to the end of September. The flowers are of bright golden-bronze colour, which is effective during the daytime as well as in artificial light. It is suitable alike for disbudding and for spray blooms. As members of the Floral Committee had inspected the variety growing, the first-class certificate was awarded unanimously. To Chrysanthemum Mrs. Phil Page.—This is a rich reddish bronze counterpart of the former variety and is equally good disbudded or in spray form. This variety had also been inspected growing and received a unanimous award. Both varieties were submitted by Mr. Philip Ladds, Swanley Junction, Kent.

TRADE NOTE

It may be of interest to our readers to know that Messrs. Barr and Son have just received a consignment of the Sacred or Good Luck Lily from China, the first importation since the autumn of 1913. This is a variety of polyanthus narcissus which has been cultivated for generations in China, and produces more flower heads to the bulb than any other variety. It is easily grown in pots in pebbles and water.

THE GARDEN

VOL. LXXXVIII.—No. 2761. OCTOBER 18, 1924

A PAVED WALK SURROUNDED BY RAMBLERS.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

PLEASE REMEMBER TO MENTION "THE GARDEN" WHEN ANSWERING ADVERTISEMENTS.

ROSES

ROSES are beloved of poets—which might make you imagine that I have been digging into a dictionary of quotations to find suitable passages around which to write a few unnecessary words on roses. My remark, however, was introductory to saying that roses have always held the most prominent place of all flowers in the world's literature. Surely the reason is that they are unostentatious and that their simplicity is one of their greatest charms. Other flowers come and other flowers go in spasms of extreme popularity, but from the dawn of time roses have held the affection of mortals so chastely and so firmly that they are still the favourite flower.

It is not only in literature that the rose is pictured; old Indian and Persian miniatures frequently depict a rose in their flowery meads, while old mediæval manuscripts are full of them. Italian pictures often show roses in the background, usually climbing a palisade or rambling over a wall: in fact, the frequency with which they are found in art or mentioned in literature of all ages proves that the rose was constantly grown and beloved by people of all classes. Folklore is also on occasion connected with the rose. Did not Aphrodite fall into a bush of white roses while hurrying to tend her wounded lover? The thorns tore her white skin so sorely that ever after her blood has dyed the white roses a deep red. Roses are often mentioned in Maypole celebrations. Which only proves that love of the rose lies very deep in our hearts.

This love seems to come from the fact that the rose is the personification of all that is pure and unspoiled. Even with our modern craze for improvement it is obvious that a rose is always a rose, which cannot be said for many of our garden flowers. The shape may alter slightly and the colour be modified in various ways, but it remains a rose for all that. The only fundamental change appears to me to be the increasing lack of fragrance. In the old days and farther to the east even at the present time its fragrance is no doubt one of its main charms. Miles of roses are grown in the Balkans, in Persia and in India simply for the purpose of distilling the essence, but in the sophisticated west we are too much inclined to limit our perception to exterior appearance and to leave the essentials an inferior second. After all, the love of the rose does not depend solely upon its present appearance—that I firmly believe; rather is there a great deal of this love born in us, a legacy from countless generations who loved the rose for itself when flowering plants were few. Some day somebody will expound to us the psychology of flowers and explain why the beauty of the magnolia leaves us startled but cold, and why the rose, even a miserable and bedraggled rose, reflects an inward light and makes us warm and contented.

It is not that in the old days roses were not appreciated for decoration. Even in Roman times they were grown out of season and counted a luxury if produced in the winter; but it is certain that in days gone by there was more of the symbolical and less of the ornamental in the love of human beings for roses.

It is pleasant to see that something of this original admiration for simplicity and purity remains, for you frequently hear of the old Scotch roses or the York and Lancaster being asked for where they were forgotten fifteen years ago. Perhaps mankind is getting tired of playthings manufactured by itself for its own amusement and is returning to that old love of flowers that was not far apart from religion. If so, it is a good omen; for artificiality in anything is supposed to be a sign of decadence, and many of our garden flowers approach the artificial.

At any rate there is little doubt that a rose in any form is worthy of our sincere respect and affection. The rose cult is founded on a solid foundation deep down in our hearts and it is worthy of all the encouragement that we can give it. The Americans in their enthusiasm for strange cults have started a publication called "For Better Delphiniums." These stately Junoesque flowers are great favourites of mine, but they are raised in such perfection at the present time that this ebullition on the part of our American friends is perhaps a little excessive. If they had only directed their steps in the direction of a quarterly journal devoted to roses, it would have been more appropriate, for there is no flower so beloved the world over.

E. H. M. C.

PERNETIANA ROSES

BY G. LAPLACE.

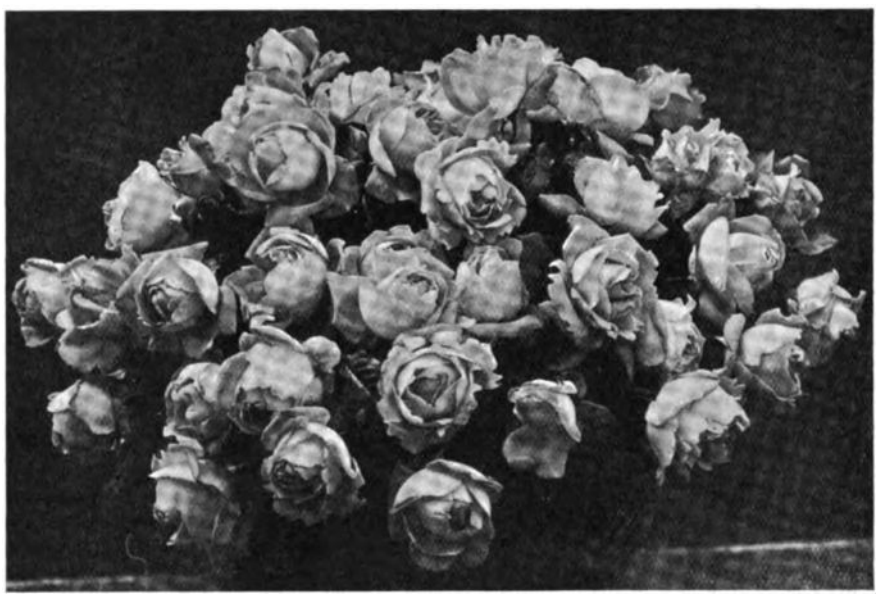
M. LAPLACE WAS IN CHARGE OF THE FAMOUS ROSE TRIALS AT BAGATELLE, NEAR PARIS, FOR MANY YEARS; SO FEW CAN SPEAK WITH SUCH AUTHORITY UPON ROSES.

THE appearance, twenty-five years ago, in the year 1900, of the first variety of a Pernetiana rose caused a sensation with the novelty of its colour. It was the result of crossing a form of Rosa lutea with a hybrid tea. M. Pernet Ducher of Lyons decided to try to raise roses, either yellow in colour or with a warm or coppery tinge, and the first attempt, resulting in Soleil d'Or, confirmed the hopes of this famous grower.

In other classes of roses yellow colours certainly exist—for example, in some of the teas—but they are inclined to be tender; Rosa lutea, on the other hand, is hardy, and at the same time is a vigorous grower, while its flowers are a good yellow. One of its varieties, called Persian Yellow, with double flowers, was a parent of Soleil d'Or, while the other was Antoine Ducher, a hybrid tea.

Soleil d'Or is a remarkable rose in the sense that its flowers are very full, of a colour varying from orange-yellow to a reddish orange; the growth is strong, but the bush is not heavily branched, while it is as floriferous as its parent, R. lutea. From the same batch of seedlings came Rhodophile Gravereaux, a very fine rose with single flowers, extremely vigorous and of a charming colour of soft rose shaded with yellow towards the centre.

M. Pernet Ducher's series of crosses have been so successful that he has increased his right to be considered the foremost raiser of roses in the world. In addition to his crosses several sports have appeared, while enthusiasts of other countries have also raised excellent Pernetiana varieties.



ROSE QUEEN ALEXANDRA, ONE OF THE MOST CHARMING OF PERNETIANAS.

At the International Exhibition held in London in 1912 the *Daily Mail* offered a large prize for the best rose exhibited. This was won by M. Pernet Ducher with the marvellous Mme. Edouard Herriot, the *Daily Mail* rose. Owing to its special colour—quite new in roses—of terra cotta shaded with yellow passing to clear rose, it aroused the admiration of countless visitors at this splendid exhibition. It is unnecessary to add that it is a vigorous grower and very free flowering.

At the present time there are, perhaps, more than a hundred Pernetiana hybrids, while the number is increasing rapidly, particularly as the remarkable Mme. Edouard Herriot is a good seed bearer and has given forth numerous offspring, not always worthy of their parent, owing to the haste with which certain raisers have placed them on the market before their worth has been proved. At the start it was easy to distinguish a Pernetiana rose; it is now somewhat difficult to point out the distinction between them and some other classes. In fact, hybrids obtained by crossing the first varieties a second time with hybrid teas follow the form of the latter; a careful examination, however, will show the influence of Rosa lutea by the number of straight thorns, the glandular flower stems and, above all, by the yellow colour or various tones of copper or rose more or less tinted with yellow at the base of the petals or on their under surface.

Soleil d'Or has a corolla in the form of a cup something after the shape of ramblers; varieties coming immediately after it have also this form, but their numerous progeny are more like hybrid teas in appearance. From the cultural point of view Pernetianas require the same treatment as other roses, the same temperature, moisture and light; but regarding soil a cool, deep loam gives the best results. Soleil d'Or, Juliet and varieties akin to them require to grow to some height to get the best flowering results, with a further growth if they are to flower in the autumn. Other kinds follow the habits of the hybrid teas.

In view of the number of first-class varieties a selection must be made, but taking into consideration certain facts, particularly that of an exceptional colour, some of even mediocre merit should be included in a list. At any rate, Pernetiana roses should be grown in every garden, large or small, and should be represented by a number of varieties owing to their vigour, their varied colours and their habit of flowering profusely over a long period.

Here is a list of good varieties which should give absolute satisfaction:

ANGELE PERNET (Pernet Ducher, 1924), a splendid rose, vigorous, of good habit, carrying quantities of smallish flowers, semi-full. Clear fiery red in colour, strongly tinged with yellow at the base. Very highly recommended.

ARTHUR R. GOODWIN (Pernet Ducher, 1909), reddish orange passing to salmon-rose.

ARIEL (Bees, 1921), orange-yellow tinged scarlet.

BEAUTE DE LYONS (Pernet Ducher, 1909), vigorous, with cup-shaped flowers, terra cotta, very free flowering.

CHRISTINE (McGredy, 1918), large flowers of a deep golden yellow, foliage of a brilliant green.

CONSTANCE (Pernet Ducher, 1915), fine cadmium yellow passing to golden yellow, large cup-shaped flowers.

ELVIRA ARAMAYO (Looymans, 1922), a strange colour quite unlike that of any other rose; it is nearly approaching an Indian red, strongly tinged with yellow at the base of the petals. The plant is very vigorous, while flowers of medium size are borne very freely.

FEU JOSEPH LOOYMANS (Looymans, 1922), a very pretty rose, vigorous, of a good yellow colour with an apricot centre.

GEISHA (Van Rossem, 1920), extremely vigorous, very free flowering, golden yellow.

GOLDEN EMBLEM (McGredy, 1917), large flowers of intense golden yellow with a few faint streaks of carmine on the outside.

INDEPENDENCE DAY (Bees, 1919). Its habit, growth and floriferousness make it one of the best introductions of the past few years. Its colour of flaming yellow and orange-apricot is particularly attractive.

Digitized by Google

JEAN C. N. FORESTIER (Pernet Ducher, 1919), large full flowers, carmine tinged with red and yellow. The bush is very vigorous, while the foliage is of a vivid green. Particularly immune from disease.

JULES TREBART (Barbier, 1920), very full flowers, salmon-rose with a coppery centre.

JULIET (Wm. Paul, 1910), one of the most remarkable roses in the class, large flowers very full. The colour is rosy red, while the reverse of the petals is old gold, making a very original contrast.

LOLITA ARMOUR (Howard and Smith, 1921), good growth, large full flowers terra cotta.

LOUISE CATHERINE BRESLAU (Pernet Ducher, 1912), one of the most hardy and vigorous of the Pernetianas; large flowers of a fine salmon-pink, suffused copper.

LYONS ROSE (Pernet Ducher, 1907), salmon-rose suffused with yellow.

MABEL MORSE (McGredy, 1922), clear golden yellow, large full flowers, scented, a vigorous-growing bush.

MME. EDOUARD HERRIOT (Pernet Ducher, 1912).

MARIE ADELAIDE (Soupert, 1912), orange, keeps its colour well. A very fine acquisition.

MISS CONNOR (A. Dickson, 1920), yellow flushed with lemon at the base.

MRS. BULLEN (Pernet Ducher, 1916), carmine flushed with yellow.

MRS. BECKWITH (Pernet Ducher, 1922), small flowers very full, yellow with golden bud.

MRS. FARMER (Pernet Ducher, 1918), golden yellow, reverse of petals reddish apricot.

MRS. S. K. RUDGE (Howard and Smith, 1920), rich canary yellow flushed with salmon-rose.

MRS. WEMYSS QUIN (A. Dickson, 1914), intense canary yellow suffused with orange-yellow. A fine variety, very vigorous and free flowering.

MURIEL DICKSON (Hugh Dickson, 1915), vigorous, large flowers of a deep coppery red.

PAX LABOR (C. Chambord, 1918), large flowers pale golden yellow, becoming deeper as they open.

ROSE INDEPENDENCE DAY.

THE LARGE, DEEP GOLDEN YELLOW BLOOMS OF CHRISTINE

RAYMOND (Pernet Ducher, 1916), a good variety, soft peach becoming deeper rose towards the centre.

RAYON D'OR (Pernet Ducher, 1910), small growth, flowers of an intense golden yellow.

REV. WILLIAMSON (Pernet Ducher, 1921), very vigorous, numerous terra cotta flowers flushed with carmine.

SOLEIL D'OR (Pernet Ducher, 1900). See above.

SOUVENIR DE CLAUDIUS PERNET (Pernet Ducher, 1920), the best rose of the class—very vigorous and fine foliage—flowers during the whole season, very free flowering, pure buttercup yellow and of a perfect form. The long bud is sometimes tinged with red.

SOUVENIR DE GEORGE PERNET (Pernet Ducher, 1921), as vigorous as the last-named, extremely remarkable for the size of the flowers—Indian red in colour shaded with yellow; extremely hardy. The last two varieties have been named in honour of the two sons of the raiser who died fighting gloriously in the Great War of 1914–18.

SOUVENIR DE GEORGE BECKWITH (Pernet Ducher, 1919), large flowers of salmon-rose flushed with yellow.

SOUVENIR DE R. B. FERGUSON (Ferguson, 1922), a splendid variety of moderate vigour, with fine foliage and magnificent flowers, apricot yellow flushed red on the reverse of the petals.

THE QUEEN ALEXANDRA (McGredy, 1918), the most delightful rose of the class, distinguished by its intense carmine colour suffused with gold on the reverse of the petals, making an agreeable contrast. The bush is only moderately vigorous.

VISCOUNTESS ENFIELD (Pernet Ducher, 1910), large flowers copper-rose.

WILLIAM F. DREER (Howard and Smith, 1920), extremely vigorous, well branched of fine growth, flowers throughout the season, large, very full, soft rose, golden yellow at the base.

WILLOWMERE (Pernet Ducher, 1913), a fine variety, very floriferous, salmon-rose tinted with yellow at the centre.

A RETROSPECTIVE APPRECIATION

OF THE NEW ROSES OF 1921

THE period which has intervened since 1921 has afforded sufficient time to secure a thorough trial and fair experience of those new varieties introduced in the year under review, and enables a decisive judgment to be formed upon those of outstanding merit, or proved excellence, or novelty.

The types selected cannot as yet be called the survivors, for there are unquestionably others not referred to hereafter which may yet establish their worthiness to a place in the garden.

Of the new varieties introduced in that year eighty-six were put down and tried out at Oxted. The result can be summarised briefly by the statement that the majority cannot, unfortunately, lay claim to novelty or to any marked advance upon those types we have already got. In this view criticism is mainly directed along the lines of the worthiness or otherwise of the type to an established place in a bed in the rose garden. Undoubtedly certain types may have points of merit and claims as exhibition roses, for growth under glass, or other special qualifications. These latter considerations appear to be of far less moment to those who grow roses primarily as a hobby than the major consideration previously enunciated.

Of the hybrid teas, two varieties of Messrs. McGredy are to be relied upon:

ETHEL JAMES, a five-petalled single rose, red flushed orange, somewhat similar to Isobel, but with a softer colour in the flowers, and a plant shape more compact and bushy.

PRINCESS VICTORIA.—Scarlet crimson blooms, with wonderful dark glossy foliage. Is an early bloomer. It should be closely watched for black spot, which must be attacked in time and eradicated, otherwise every leaf will go and the plants will die.

Two of Messrs. B. R. Cant's hybrid teas have proved themselves, viz.:

MRS. OAKLEY FISHER.—The best single rose produced for some years past. Blooms are orange yellow coloured, excellent for table decoration. The plants, which grow well, have a nice bushy shape.

A SHAPELY BRIGHT YELLOW BLOOM OF ROSE REV. F. PAGE ROBERTS.

ROSE SUNSTAR, OF EXCELLENT BUSHY GROWTH AND LARGE TRUSSES OF BLOOM.

REV. F. PAGE ROBERTS.—Bright yellow blooms of good size and shape. A dozen plants of this variety, grouped together, make a fine mass of colour.

MRS. HENRY BOWLES.—(Chaplin Brothers, Limited.) A warm pink. Grows well massed in a bed.

MINNIE SAUNDERS.—(Elisha Hicks.) A really free bloomer. Scarlet flowers with good erect plant growth.

SUNSTAR.—(Alexander Dickson and Sons, Limited.) This is well worthy of a bed entirely to itself, if only for its unique splashed red and yellow colouring. The plants do not grow tall, but are none the less reasonably strong.

ARIEL.—(Bees, Limited). This variety has proved so very effective this season that it has been decided to grow still more. Orange yellow colour, prettiest in bud, with adequate growth.

MAUD.—(William Paul and Son, now Chaplin Brothers, Limited.) Coral-coloured blooms in big trusses and of good foliage. The growth erect and rather tall.

Two dwarf polyanthas are of outstanding merit, viz.:

CORAL CLUSTER.—(R. Murrell.) Pretty coral-coloured blooms, but displaying an unfortunate tendency always to "throw back" to its Orleanistic parent.

DOROTHY HAWORTH.—(Bees, Limited.) Its only fault, if such it can be called, is that it grows almost too strong for a dwarf polyantha. The trusses of bloom are very heavy. Colour pink, in light and dark shadings.

Of climbers undoubtedly the best of this year is:

ALBERTINE.—(Barbier). A climbing Wichuraiana with flowers similar to Mrs. A. R. Waddell. Of excellent growth and a profuse bloomer. Also—

CLIMBING MME. EDOUARD HERRIOT.—(Ketten Frères.) A climbing sport of the well known Pernetiana rose. Blooms well, with fairly strong growth.

The foregoing have produced, under the conditions and environment of Oxted, the most successful results of the series of 1921. On the other hand, it must not be inferred for one moment that the

Digitized by Google

remainder are failures, or not worth growing, for, indeed, some of them are quite good. The types specially mentioned, and this cannot be over-emphasised, are a personal selection based upon our own trials, and having strict regard to garden varieties alone.

This appreciation means this, at least, that they have entirely justified their place in the garden of every true lover of the rose, and will add much to his joy and pleasure in the cultivation of this queen among flowers "in her infinite variety."

Oxted. HERBERT L. WETTERN.

(*To be continued.*)

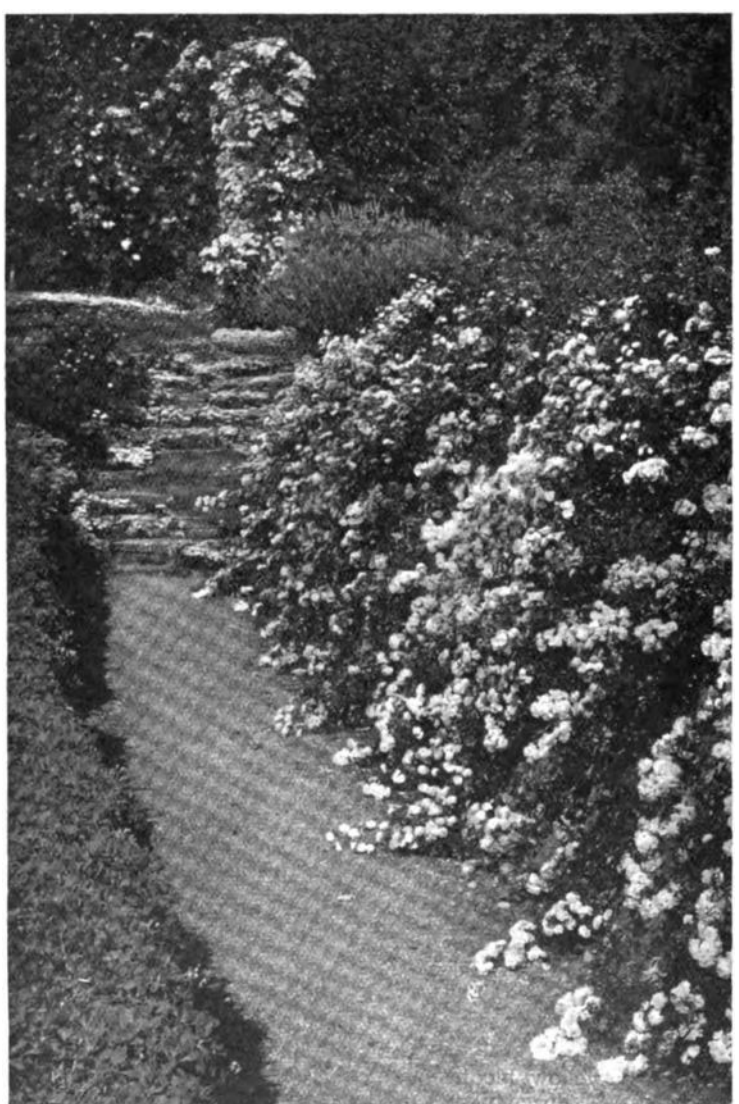
NOTES on the CULTIVATION of ROSES

THE doubts and fears of the beginner in rose growing nearly always concern soil—its suitability or otherwise; but, provided exhibition roses are not the object in view, such worryings nearly always prove to have been groundless, for quite good roses may be grown in any ordinary garden soil. The ideal soil for roses is a rich deep loam, a trifle inclined to be heavy. But as ideals, especially in gardening, are seldom attained, the wisest course is to make the best use of the soil of the garden, ameliorating it as far as circumstances permit.

Pure clay and pure sand will not grow any plant, no matter how lowly, so that rose growing in such would be foredoomed to failure. But with the sandiest of sandy soils and the heaviest clay much may be done, especially if after the soil preparations have been completed the right types of rose are chosen. Even in some of the very sandy soils in parts of Norfolk, the Wichuraiana hybrids grow and flower remarkably well, and it is this free-flowering cluster type that should be selected for very poor soils.

Where expense is no object, good loam may, of course, be imported, and then it is only a matter of making up the beds and planting them. Without going to this expense, these poor soils can generally be greatly improved by the addition of such materials as old potting soil, leaf-mould and any decayed vegetable matter that may be on hand. The best manure for roses, and especially on light soils, is thoroughly decayed farmyard manure. If this is not procurable, Wakeley's hop manure will be found a good substitute. This hop manure gives excellent results, and is of great assistance to the soil in addition to being a valuable plant food. The especial worth of both these substances on light soils is that, besides adding much-needed humus, they absorb and retain till needed large quantities of moisture. Chemical manures are not advisable for use in light soils when preparing them for planting, but bone-meal, if used at the rate of 6 oz. to the square yard, will provide a useful, slowly yielded store of phosphates. But whatever sort of manure is used for the rose beds, it should be well mixed with the soil and not placed in a layer under the top spit, as is so often done.

The first consideration when preparing a clay and, indeed, any heavy soil should be drainage, for unless the soil is properly drained roses cannot thrive. The old-time method of improving a clay soil was by burning it, but nowadays this is too expensive a method. The application of lime has, to the beginner, a surprising effect on heavy soils. A dressing of from 8 oz. to 10 oz. of freshly slaked lime per square yard soon breaks up clayey soils and deprives them of a deal of their sticky nature, transforming them into most valuable and fertile soils, which are capable of growing the finest of roses. But it must always be remembered that clay soils respond, even more than any others, to thorough and frequent cultivation. If they can be thrown up rough and left for the winter frosts to act upon them before being levelled for planting, an immense improvement in their texture is the result.



WICHURAIANA ROSES ARE ADMIRABLY SUITED FOR RETAINING WALLS.

With the medium soils, which are neither heavy nor light and which are decidedly in the majority in gardens, drainage is not usually necessary, and the preparation consists in digging as deeply as possible and adding manures as already suggested, bearing in mind that the rose is of the nature of a permanent crop and should be treated accordingly.

While the form and design of the rose garden does not come within the scope of these notes, it is proper to remark upon the need for shelter from keen winds. Abundance of air and sun are requisite and necessary for success in rose growing, but shelter is equally necessary. If the site is exposed to rough winds the needed shelter may generally best be provided in the form of a hedge, and for this purpose it is such hedges as of Penzance briars, the common sweet briar and Cydonia (Pyrus) japonica varieties among deciduous shrubs, and yew, cypress and holly of the evergreens that are most suitable, according to the height of shelter needed. But any hedge, except perhaps the lowest of hedges, requires time before it becomes effective, and where the shelter is required immediately it can be provided by such temporary means as wattle hurdles or stretching sheep netting along the windy side of the roses. When the permanent hedge has become of full height, these material substitutes will, of course, be taken down. Another and quite effective form of shelter may be obtained from a wire fence to which is trained some of the freer-growing rambler roses. But Crimson Rambler should not be so used, as it is too liable to attacks of mildew. Grüss an Teplitz, Tea Rambler, Félicité et Perpétue, Dundee Rambler, Blush Rambler and Bennett's Seedling are

Digitized by Google

examples of suitable varieties. But if, as it should be, the screen of roses is to be really effective, the temptation to plant a number of varieties should be resisted. For a short hedge only one sort should be planted, and as that one sort the writer would choose Grüss an Teplitz.

Similarly, in the rose garden itself, or in the rose border, most pleasure and satisfaction are nearly always obtained when the number of varieties is restricted. Likewise, unless the beds are quite large, only one variety should be planted in each bed. If the garden design has provided rose beds of varying sizes—the present writer has arrived at the definite opinion, after a deal of consideration and having seen many rose gardens, that the best effect is seen when the varieties are so arranged that the brightest coloured varieties are placed in the largest beds. A large bed of a white or pale-coloured variety gives a cold and, except for a brief season, depressing effect.

Any attempt at a selection of varieties for a beginner to grow teems with difficulties and, as one could only generalise, would not serve any really useful purpose. The special object of the rose garden should be known; the nature of its soil, exposure and the personal tastes of the garden owner should also be considered. All the rose growers who advertise in THE GARDEN are invariably ready and willing to place their expert knowledge at the service of customers when the latter make their requirements known; and then, there is the Editor himself, who draws attention to his admirable "Service for Readers" on the first page. A letter to him setting out just what is wanted will bring a prompt reply of great value.

Whatever sorts are decided upon they should always be purchased from a reputable grower. We all know quite well that roses of sorts may be bought at auction sales and from certain stores at very low prices; but the risk of disappointment is too great to be run—and it is a penny-wise-and-pound-foolish policy to attempt to save a trifle on the plants after having prepared the beds.

The planting of the roses should be a deliberate operation and only performed when the weather and the soil are suitable. The gardener's test of the proper condition of the soil is to tread on it and see whether or no an undue quantity sticks to his boots; if so, he waits. The roses can always be temporarily laid in until the right time has arrived. Rose trees should never be planted when the roots are at all dry. If, when they arrive, the roots are seen to be dry, they should be placed in a pail or tub of water for a couple of hours or so to become thoroughly moistened. The soil mark on the stems is a good guide as to the correct depth to plant. If the soil is light the plants should be set a trifle lower than before, while with a heavy soil the reverse should be done. Any bruised or broken roots should be cut cleanly off. The hole for the plant should be larger than the spread of the roots, so that they may be regularly laid out to their fullest extent, care being taken to work the soil well around every root. If the garden soil is at all coarse it is a good practice to have ready sufficient prepared soil to cover the roots of the plant. A gentle shaking of the plant as the soil is being spread around the roots will ensure that they are in close contact with it. In all soils firm planting is essential.

Standard roses should be secured to stout stakes immediately. The stakes should be firmly driven into the ground before the rose is planted, so that there is not the slightest danger of injury to the roots. During dry weather the newly planted roses should be well watered and, if they are still in leaf, it is an advantage to spray the foliage on fine days for a fortnight. A. C. B.

COOL-GROWING ORCHIDS

ODONTOGLOSSUMS AND THEIR HYBRIDS.

THE premier position among the cool-growing orchids can easily be assigned to the odontoglossums, their numerous fine hybrids, and the odontiodas, the latter being bi-generic hybrids between the odontoglossums and the cochliodas, chiefly the orange-scarlet C. Noetzliana. No collection, however small, is complete without a few odontiodas, their brilliant flowers, graceful arching racemes, and the ease with which they can be grown successfully rendering them well-nigh indispensable. Among the odontoglossums there is a wide selection, even if the grower confines himself to the varieties of the popular O. crispum. Of the host of hybrids the beginner will find the following useful: OO. percultum, ardentissimum, amabile, Rolfeæ and eximium; but the best plan would be to visit some nursery where they specialise in orchids. The odontiodas are also both varied and interesting, and the nucleus of a collection could be formed by the acquisition of OO. Charlesworthii, Bradshawiæ, Chanticleer, Queen Mary and Vuylstekeæ.

For preference, a low span-roof greenhouse running from north to south, should be chosen; it ought to be away from buildings and trees, and in an open situation. Where a collection of odontoglossums and odontiodas is cultivated a few will need repotting at intervals throughout the year, but the bulk will require attention in August and September. Annual disturbance is not necessary, and providing other cultural details are correct the compost will remain in good condition for at least two years. When it is decided that a plant needs repotting, care should be taken to see that the new growth is about to produce roots, then it rarely feels the effect of being disturbed. Over-potting should be guarded against, but enough space should be allowed for the further development of two pseudo-bulbs. The pots are filled to one-fourth of their depth with drainage material, over which is placed a layer of moss to secure a free outlet for water. The rooting medium consists of Osmunda fibre 3 parts and chopped sphagnum moss 1 part. The latter is relieved of all weeds and washed to free it from snails, while the former is cut up into inch lengths and the dust removed with a fine sieve. It is well mixed together a few days before it is used, and should be in a moist but not wet condition. When repotting a plant the old decayed compost is picked out with a pointed stick, dead roots are cut off, and any useless back pseudo-bulbs removed. As a rule, three behind each lead or growing point is ample, and if it is desired to increase the stock the pseudo-bulbs so removed can be utilised for propagating purposes. Place them in small pots with plenty of drainage, and give them a shady part of the house until they produce a new growth, when they are treated the same as established specimens. When the plant is ready, the roots are spread evenly over the soil, and then more compost is pressed moderately firmly among the roots and brought level with the rim of the receptacle. The plant is arranged so that the young growth is as near the centre of the pot as possible.

If the variety is a valuable one the rhizome can be severed at intervals a few weeks prior to repotting, then growing points are often formed before the plant is disturbed. In this way healthy young plants are obtained, and when the repotting is done the old pseudo-bulbs are given a separate existence. For a few weeks after being repotted the roots should not be over-done with water, a light spray overhead will help the plants to get re-established, and they should be shaded from strong sunlight. Ventilation is necessary, and whenever possible the bottom ventilators, viz., those in the wall, should be open, but the top ones are only opened during mild and congenial weather. An average temperature of 55° to 60° Fahr. is maintained, but during a very cold spell 50° Fahr. will be ample, while the maximum figures are exceeded in summer when the sun is strong. Much, however, can be done to keep down the temperature; the blinds are lowered early, just before the sun reaches the glass, and the house is thoroughly damped down by sprinkling water on the stages, floor and walls. Cleanliness is an important factor, and thrips are occasionally troublesome, but this pest can be destroyed by fumigation.

The chief points in cool-house orchid culture are judicious ventilation, a more or less moist atmosphere according to the period of year, shade from all strong sunlight, careful watering at all times, freedom from insect pests, and in never allowing a plant to produce its full complement of flowers unless it is well provided with roots and is healthy. Slugs and small snails must be watched for, or they will devour the flower spikes just as they appear at the base of the pseudo-bulb. T. W. BRISCOE.

ROSE NOTES FROM "THE GARDEN" 1871—1924

IT seems fitting in this, our Special Rose Number for 1924, to give extracts from articles on roses in back numbers of THE GARDEN. It is interesting to dip into old volumes and see what was popular in the 'seventies. From the first volume of THE GARDEN, 1871–72, we have taken two extracts, both from articles by S. Reynolds Hole, the famous Dean Hole. Many of the roses in his list have entirely disappeared, but no doubt a few are still to be found in some old-fashioned gardens.

"I have only to append, in its completion, the little list of very hardy roses for beginners, to be planted immediately in soil well drained and dry and manured, away from trees, but not in a bleak, exposed position:

Gloire de Dijon, Noisette.
Souvenir de la Malmaison, Bourbon.
Alfred Colomb, H.P.
Baroness Rothschild, H.P.
BaronnePrévost, H.P.
Caroline de Sansales, H.P.
Comte de Nanteuil, H.P.
Général Jacqueminot, H.P.
John Hopper, H.P.
Jules Margottin, H.P.
La Ville de St. Denis, H.P.
Mme. Boutin, H.P.
Mme. Boll, H.P.
Mme. Caillat, H.P.
Mme. Clemence Joigneaux, H.P.
Mme. Rivers, H.P.
Maréchal Vaillant, H.P.
Senateur Vaisse, H.P.
Victor Verdier, H.P.
Blairii No. 2, Hybrid China.
Charles Lawson, Hybrid China.

I omitted the last rose when speaking of those which bloom only once; but he has pleaded with me for admission every time I have passed through my rose garden, reminding me how many years he has faithfully served me with large and beautiful roses, and at last convincing me that I should do an injustice to him, to myself, and to the young amateur if I did not include him in my list." 1872.

"BARONESS ROTHSCHILD.—One of the most beautiful and, so far as I have tested it, one of the most reliable of our light-coloured roses, for though short in limb, she is strong and sturdy in constitution. It seems ungraceful to describe a lady thus, but in writing and speaking of roses one meets with strange antitheses. Of this very rose, and only the other day, a rosarian said to me, 'Ah, yes—isn't she lovely!' and then added, with a tender pensiveness, 'I do believe that I've given the Baroness more than double her share of—manure!'" 1872.

Then comes an interesting query and answer from the volume of 1874, obviously answered by the Dean in his inimitable style.

"GARDEN ROSES AND HUMAN HAIR.—I have been informed that human hair is now used in the cultivation of roses. Can any of the readers of THE GARDEN tell me if they have tried it, and if so, what soil it is the most suitable for?—A. W. (S. R. H. replies that he knows something of the converse of this theory, *i.e.*, of the application of roses in the cultivation of human hair, having largely used 'rose oil' in his youth, and believing that when Leech's hair-cutter compared the perfume of a bean-field to 'the most delicious 'air oil,' that particular oil was in his thoughts; he also desires to express his admiration of roses, not artificial, as ornaments of the hair, and is not at all surprised that she wore a wreath of them and made such a profound impression upon the gentleman, who sang her praises that night when they first met; but he has no experience of the influence of ringlets upon roots, whether ebon locks would darken, or curls, which vulgar little boys call carroty, would brighten the complexion of the rose, having only torn his hair, metaphorically, in the rosarium, when frost or fungus have destroyed his hopes.)

Next comes a topical note which is applicable at the present time and, in fact, is a useful suggestion for the planting of climbing roses in the open.

"CLIMBING ROSES ON GRASS.—There are remedies for some of our garden troubles if people will only try to find them out. There are few more unprofitable and tedious labours than that of eternally pruning and training climbing plants. In many positions we can never avoid this in a modified degree; in others we can avoid it, and get a much more beautiful result in doing so. For example, many vigorous trailers and climbers are more beautiful planted out on banks of turf and let alone than under the most careful training. Such effects are, of course, most suitable for the wilder and more picturesque parts of gardens; but in a modified degree they may be carried out in any part of the garden. By this is meant that

TYPICAL TEA ROSES FROM "THE GARDEN" OF 1886.

Digitized by Google

climbing roses might be allowed to grow naturally, and be at the same time so thinned out and otherwise attended to that they would not become weak in flower or growth." 1877.

We give the next note with its accompanying illustration as a sample of the form of tea roses in the 'eighties—not so different in form from those grown nowadays.

"A BUNCH OF TEA ROSES.—Many are the beautiful forms that have been produced in this lovely section of our cultivated roses; their beauty is undoubtedly of a more refined order than that of the Hybrid Perpetuals, while their individual characters are, as a rule, more clearly marked. Triomphe de Rennes, the subject of the present illustration, is a rose of eminent merit, excellent in form, most delicate in colour—warm white deepening to full lemon colour—and unusually distinct in foliage. The leaves are deeply toothed and of a dark glossy green, with a characteristic waving or twisting, so that the identity of the bush cannot be doubted when out of flower; these features also give it a distinctly ornamental aspect. Its high value as a cut flower when easily arranged in a simple glass may be seen in the engraving. To be quite correct, Triomphe de Rennes is a Noisette, a subdivision commonly classed under the head of Tea roses." 1886.

A MODERN HYBRID TEA.

During the 'nineties there seemed to be little of importance in the rose world, but in 1903 we find the first mention of Dorothy Perkins, introduced late in 1902.

"ROSE DOROTHY PERKINS.—A very beautiful hybrid of the wichuriana class, with pink flowers nearly or quite 2ins. across and rather light in the centre. The glossy foliage is distinctly pleasing, and closely approaches to evergreen in this section. A very charming variety. A.M. May 20. From Mr. E. Potten, Cranbrook, Kent."

In 1905 we pick out a note on Richmond which had just been received at Kew.

"ROSE RICHMOND.—This new Hybrid Tea, judging from a couple of plants flowering in the greenhouse at Kew, appears likely to rank with, or even excel, Liberty as a forcing rose. It is a rather brighter red than Liberty and very fragrant. Although only small when received, it is growing freely, and promises to be a perpetual bloomer. Of American origin, it is said to be a cross between Lady Battersea and Liberty. From the demand for plants in America it has evidently caught on, 150,000 having already been disposed of.—A. O."

Mme. Abel Chatenay was exceedingly popular in 1907, and is still third in our list of the best six hybrid teas, a fine record of popularity.

"ROSE MME. ABEL CHATENAY.—I regard this as queen of the rose garden. It seems happy almost anywhere, and makes tall, strong, leafy growths, upon which the exquisite flowers are borne in profusion. It is not only vigour of growth and leafiness that constitute the chief attraction, but the flowers are of very distinct shape, the petals pointed and composing a full fragrant, handsome bloom, while the colour is a mingling of salmon and rose, quite a distinct shade, even in these days, when new roses are plentiful. I commend this rose, and advise all who have not got it to do so in the coming autumn. Another rose I greatly admire is La Tosca; it is of the Viscountess Folkestone race, but the stems are stronger and the flowers held more upright. The colour is deeper. La Tosca is a clear pink rose, very sweetly scented, and excellent for cutting. It will probably become very popular." 1907.

In 1910 the Editor answers a complaint that General McArthur was too flat in form.

"ROSE GENERAL MCARTHUR.—I note on page 494 'Alvaston' does not care for this rose. How strange are the tastes of individuals! I am acquainted with those who look upon this as being one of the most useful of all roses for freedom of flowering, stiffness of flower stems, rich colour and, what is important, its sweet fragrance. General McArthur was sent out by Messrs. E. G. Hill and Co. in 1905, consequently it is of American origin, and has made much progress in this country since it was introduced. From mildew it is immune with me, and that is another point in its favour."

There is a plea for the fuller recognition of the old China rose in 1915, which is timely, for they are now coming back again into our gardens.

"We have an idea that the exquisite old fashioned roses which bear this distinctive name are in danger of being ignored. Yet it cannot be questioned that some of their modern representatives are sufficiently effective in their form and colouring to preserve this charming race of fragrant roses from premature extinction. Many of them are as delicately tinted as the Teas or even the Rosa pernetiana creations. Since the memorable days when the late Dean Hole of Rochester sang the praises of the 'Brave Old Monthly,' the China roses have made a very remarkable advance in the direction of artistic perfection."

While in 1924 we find that the six most popular hybrid teas, according to the vote of our readers, are General McArthur, Ophelia, Mme. Abel Chatenay, Los Angeles, Lady Pirrie and Mrs. Henry Morse. The dates of their introduction into commerce were 1904, 1912, 1894, 1916, 1910, 1919. This proves that a rose introduced thirty years ago can still be third in the popular vote—a fine record of popularity. Thus it will be seen that THE GARDEN caters extensively for the rose lover.

FRUIT AND VEGETABLES AT VINCENT SQUARE

THE Royal Horticultural Society's Autumn Fruit Show appeals to the professional gardener to a greater extent, possibly, than either of the other big shows throughout the year. This show is essentially the gardeners' show. A common meeting ground for the craftsman in friendly rivalry to meet in open competition some of his life long friends, forgetting for the moment friend and foe alike, awaiting the decision of the judges.

MESSRS. WATERER'S EXHIBIT OF APPLES.

This is the crucial moment of his life. Is success to crown his efforts for the care and devotion taken and given, or is disappointment to follow? Whatever the outcome it would be difficult, nay impossible, to find in a body of men a finer spirit of true sportsmanship than is to be found in the gardeners on this great occasion. Success or disappointment alike creates the spirit to continue in friendly rivalry for the coveted prizes, and long may this spirit continue.

Despite the difficulties of the season—and no season passes without presenting to the exhibitor many difficult problems—this is the occasion when one is not to be disappointed. The impression on entering the Hall last week was that somehow the Show was different from its predecessors. This is explained by the fact that there were fewer trade exhibits than usual.

The Royal Horticultural Society in revising its schedule and offering prizes worthy of the occasion, has made a step in the right direction, as was evidenced by the large number of entries in competitive classes; so much so that nearly the whole of the Hall was taken for this purpose, to the exclusion of the large trade exhibits.

The impression of the Show as a whole was that it was a very fine one. Looking at it broadly one could imagine that perfection had been reached. Only when one looked very closely into the exhibits could one see the effects of the damp and sunless season.

This was particularly noticeable in the grape section. There have been finer and better grapes at previous shows. This is not a criticism in a petulant spirit. Everyone knows from experience with such a sunless season, restricted artificial heat, etc., the difficulties have been well-nigh insurmountable in bringing grapes to a state of perfection. Despite the difficulties, some of the exhibits were worthy of the occasion, others, alas, were not. Lack of colour and finish, as well as irregularity of bunch and berry were pronounced in several exhibits. In the collections of dessert fruits evidences of the season were again discernible, but on the whole the fruits were very good.

In the collections of hardy fruits there must be no stint of praise. Colour, size and cleanness of specimen dishes were marked features, equal to anything seen in more favourable years. In the single dishes section competition was again very keen, but here the usual standard of excellence was slightly lacking. In the counties' competition many fine dishes of pears and apples were exhibited.

Foremost among the trade exhibits was Mr. J. Allgrove of Langley, to whom a gold medal was awarded. Without a doubt this was one of the finest exhibits of its kind that has been seen. The staging was excellent and the specimens without exception were perfect. Chief among them was Rev. W. Wilks, Rival, Wealthy, King of Pippins, Emperor Alexander and Charles Ross apples and Marguerite Marillat and Mrs. Leden pears.

Messrs. Notcutt of Woodbridge also staged a very fine collection of hardy fruits. We do not remember seeing a fruit exhibit from this firm before, certainly not of such dimensions as on this occasion.

The hardy fruits shown by the Barnham Nurseries were also of first quality, and included such apples as Belle de Boskoop, Newton Wonder and Crimson Bramley.

Messrs. Laxton in the smaller class exhibited an attractive collection of apples and late plums, while Messrs. Spooner's exhibit of apples and pears was much admired, among the apples being Houblon and Golden Spire.

Our illustration shows Messrs. Waterer's stand of fruiting trees in pots and also gathered fruits. The main exhibit was of their fine new apple John Waterer, which bears heavy crops of exceptionally large fruit. As a cooking apple we can confidently recommend it to our readers.

The Hollesley Bay Labour Colony's exhibit of fruit grading was interesting and instructive.

Other exhibits were by Messrs. Bunyard with apples and pears; Messrs. J. R. Pearson and Sons with Apple Charles Eyre; Mr. Parsons with his Worcester Berry, a cross between a black currant and a gooseberry; Messrs. T. Rivers and Sons with apples, pears and the late Cherry Guigne de Winkler; Messrs. Daniel Brothers with their late black currant.

Everyone left the Show with the conviction that the standard of excellence was well maintained and that with a more favourable season competition will be keener and entries larger.

Note.—Owing to lack of space we are, unfortunately, unable to mention the prize-winners in the different fruit classes.

The Vegetable Show was held in conjunction with the above on Tuesday, 7th inst., and, as might have been expected, there was a large number of entries, and much of the produce was of a very high standard. Nevertheless, something appears to be wanting in the way of arrangement and staging, as there is no reason why vegetables, if properly displayed, should not be as attractive as fruit and flowers. This applies more especially to the single dish classes. In some cases, owing to certain of the competitors not staging their entries, there were serious blanks, which cannot possibly be overcome, except that some rule should be made and enforced to ensure staging.

The most important class was No. 1, which asked for twelve distinct kinds of vegetables. There were four entries, and each was of much merit. The first prize was won by Major Pam, Wormley Bury, Broxbourne (gardener, F. Streeter, a young cultivator of much promise). He showed remarkably well Exhibition leeks, Early Giant cauliflower, Sutton's Pink celery, Tender and True parsnips, very fine carrots (Sutton's New Intermediate), Dwarf Gem Brussels sprouts, Best of All tomatoes, Perpetual peas, Rochford's Market Improved cucumbers, Sutton's Improved Black beet, a very fine dish of Arran Comrade potatoes, and Ailsa Craig onions. Second, Viscount Hambleden, Greenlands, Henley-on-Thames (gardener, W. Turnham), with a remarkably fine collection, but somewhat weak in celery and onions, especially good being Acquisition leeks, Red Intermediate carrots, Best of All tomatoes, Gladstone peas and Sutton's Black beet. Third, Mr. Naylor, Grinshal, Shrewsbury, his onions and Brussels sprouts being particularly good.

Class 2, nine distinct kinds of vegetables, in which quality and size were to be shown as being most suitable for table use, brought out a very strong competition and made an attractive display. Mrs. Jenner, Wenvoe Castle, Cardiff (gardener, H. Wheeler), was a splendid first with a faultless collection: it would be difficult to imagine a more perfect set. It consisted of White celery, Golden Ball onions, Colossal beans, Gladstone peas, Aviator tomatoes, Exhibition Brussels sprouts, Arran Comrade potatoes and Matchless carrots. There was not a weak dish in it. Second, Mr. W. H. Myers, Swanmore Park, Bishops Waltham (gardener, G. Ellwood) This also was a remarkably fine exhibit and was but little behind the first prize. especially fine being Early Gem carrots, Best of All beans, Perfection tomatoes and Stirling Castle potatoes.

Digitized by Google

Class 7, six distinct kinds of salad vegetables, these were splendidly shown, Viscount Hambleden beating Major Pam with a very fine collection of celery, beet, mustard and cress, Iceberg lettuce, Best of All tomatoes, Delicacy cucumbers. Major Pam lost by a discoloured dish of endive. The lettuce in this collection was particularly fine.

Class 6, six dishes of onions. Mrs. Jenner was well first—indeed, seldom has a finer collection been seen; the bulbs were of fine size and shape, solid and of a fine finish. The varieties were Ailsa Craig, Premier, Golden Ball, Crimson Globe, Royal Keeper and Silver Globe. Second, Viscount Hambleden.

Mrs. Jenner was a very successful winner in the single dish classes, winning first prizes for Brussels sprouts, long carrots, white, purple and yellow turnips and a single dish of onions, thus winning the challenge cup for the greatest number of points. Earl Beatty (gardener, A. Bennett) was successful for scarlet runner beans and yellow tomatoes. The runner beans were a splendid dish.

In the Single Dish classes, first prizes were obtained: for French climbers and French dwarf, by Mrs. Wallis Toller, Weybridge (gardener, G. Crabb); for globe beet and long beet, by Mr. F. C. Stoop, West Hall, Byfleet, Surrey (gardener, G. Carpenter); for white celery, by Mrs. Farnham, The Height, Witley, Surrey (gardener, J. Binnington); for red celery, by Sir Charles Nall-Cain, Brocket Hall, Hatfield (gardener, T. Pateman); for cucumbers, by Mr. W. H. Myers (gardener, G. Ellwood); for leeks, by Mr. W. C. Phillips, Clarence Road, Wood Green; for marrows, by the Rev. T. G. Wyatt, Horley (gardener, J. E. Shirley); for parsnips, by Mr. W. H. Tyzack, High Wycombe; for short carrots, by Mr. W. H. Myers; for peas, by Sir Charles Nall-Cain; for white potatoes, by Mr. W. H. Tyzack for coloured potatoes and red tomatoes, by Mr. G. Thorn, Sprotland; and for any other dish (maize or Indian corn), by Sir Charles Nall-Cain.

Class 3, six kinds of vegetables: First, Mr. Day, Newnham, Berkhamsted, who staged fine Intermediate carrots and excellent leeks and onions. Second, the Rev. F. Wyatt, Yalding, Kent, with very finely coloured Intermediate carrots and good tomatoes and potatoes.

Class 4, collection of twelve varieties: First, J. H. Henderson, West Woodhay House, Newbury (gardener, J. Pike), his best being Majestic, Great Scott, The Ally and Mr. Breese. Second, Sir Charles Nall-Cain (gardener, T. Pateman), with good specimens of Majestic, Snowdrop, Arran Victory and Rhoderic Dhu.

Class 5, six immune varieties of potatoes: First, the Rev. Canon Leigh, Edenbridge, who staged The Ally, Majestic, Great Scott and Mr. Breese in good form. Second, Mrs. Jenner, Arran Comrade and Majestic being excellent among others in this collection. Third, Sir Charles Nall-Cain, Brocket Hall, Hatfield.

NEW AND RARE PLANTS.

PRIMULA SIAMENSIS.—A fine species with leaves like a primrose and semi-pendent flowers of a soft lavender with a white centre. A valuable cool greenhouse plant. A.M. Shown by the Director, Royal Botanic Gardens, Kew.

ASTER MME. E. BERNARD.—A fine Amellus, flowers 2ins. in diameter, rose lilac in colour, good general appearance. A.M. Shown by Mr. F. G. Wood.

ASTER MRS. PIERPONT MORGAN.—A good Michaelmas daisy with flowers of blush pink with pale yellow disk, graceful habit. A.M. Shown by the Hon. Vicary Gibbs, Aldenham House, Elstree.

ASTER WELLS' FAVOURITE.—A free-flowering Amellus with flowers of a pleasing mauve shade. A.M. Shown by Mr. W. Wells, jun.

CHRYSANTHEMUM J. COTTON.—An early Japanese variety. The colour is bronze red with old gold reverse. A.M. Shown by Mr. G. Carpenter, West Hall Gardens, Byfleet.

CHRYSANTHEMUM PRIMROSE POITEAU.—A fairly large-flowered early variety primrose yellow in colour, the florets are broad. A.M. Shown by Messrs. Lowe and Shawyer.

CHRYSANTHEMUM REGINALD A. ROOTS.—A fine variety with ivory flowers about 6ins. in width; the florets are twisted at the tips. A.M. Shown by Mr. W. Roots.

ESCALLONIA MONTEVIDENSIS.—A Brazilian species and not really hardy. It is a late flowerer and is attractive with the spikes of small white flowers against bright green leaves. First-class certificate. Shown by Messrs. Robert Veitch and Son.

HIPPEASTRUM SP.—The flowers are translucent white with a green tube. A.M. Shown by Major A. Pam, Wormley Bury, Broxbourne.

KNIPHOFIA NELSONII.—Rather small flowers of a good orange colour. A late-flowered species but of good habit. A.M. Shown by Mr. R. C. Notcutt.

PRIMULA SIAMENSIS, A FINE SPECIES.

ORCHIDS.

LÆLIO-CATTLEYA SARGON VAR. GLORIOSA (L.-C. Lustre × C. Hardyana).—An unusually large plant, the last made bulb of which carried a spike of four immense flowers, each measuring 9ins. across, the petals being 4ins. in width. Of rosy mauve colour, the broadly developed labellum ruby-crimson and with golden venation in the throat. First-class certificate. Shown by Lieutenant-Colonel Sir George Holford, K.C.V.O., Westonbirt, Tetbury, Gloucestershire.

LÆLIO-CATTLEYA PROFUSION VAR. ARABIC (L.-C. Serbia × C. Hardyana).—A free-growing plant which bore a spike of four flowers, the segments compactly arranged and of mauve-pink colour, the labellum standing out prominently on account of its large size and deeper colouring, the frontal area being crimson-purple, with a crisped margin. First-class certificate. Shown by Messrs. J. and A. McBean, Cooksbridge, Sussex.

NEW CHRYSANTHEMUMS

THE subjoined awards were made to new varieties by the Floral Committee of the National Chrysanthemum Society on October 6th.

Messrs. Lowe and Shawyer sent two vases of magnificent blooms of Mrs. R. C. Hamilton to show that this variety, which was raised in their nurseries and received a first-class certificate at the Crystal Palace in 1913, is identical with Cissbury Yellow, the variety which received an award of merit at the recent R.H.S. Autumn Show at Holland Park Hall. This sport crops up periodically, and has, at different times since 1913, received such names as Early Buttercup, Knaresbury Yellow and Golden Glory. The incurved form is, as was clearly shown by the blooms before the N.C.S., obtained when plants are "stopped" early in June. Plants stopped a fortnight or so later throw blooms of Japanese type but identical in colour and foliage, and it was in this form that Mrs. R. C. Hamilton, the original, received the award in 1913.

G. CARPENTER.—A large Japanese variety with fairly broad florets. The colour is almost a brassy yellow with a tinge of gold, which gives much the colour of the Australian sovereigns of respected memory. There is also just a suggestion of green in the undeveloped florets in the centre of the blooms. It seems to be a good variety for home decorative purposes. First-class certificate. Shown by Mr. G. Carpenter.

J. COTTON.—This is a smaller but sufficiently large Japanese variety of beautiful shape and most gorgeous colouring and quite the best of its type now in season. It is of rich velvety crimson colour, which seems full of life and is enhanced by the golden reverse showing at the tips of the mature florets and in the centre of the blooms. First-class certificate. Shown by Mr. J. Cotton.

PRIMROSE POITEAU.—The great value of this primrose-yellow sport from the well known white variety, Blanche de Poiteau, lies in its uncommon colouring and bold handsome form. Like the type, it is a large flower made up of substantial florets of incurving edges. First-class certificate. Shown by Messrs. Lowe and Shawyer.

REGINALD A. ROOTS.—This is a splendid, medium-sized Japanese chrysanthemum which should be in great demand. It is a very round flower made up of narrow florets which are rolled similarly to those of the best type of cactus dahlia. It has the colour of high-grade cream-laid notepaper with a slight suggestion of ivory white in the centre of the bloom. At a little distance the flowers have the appearance of fluffy snowballs. First-class certificate. Shown by Mr. L. W Roots.

SUNBEAM.—A splendid incurving Japanese variety of useful size and good substance. The broad florets vibrate rich glowing yellow colour. First-class certificate. Shown by Messrs. W. Wells and Co.

FORTHCOMING EVENTS.

October 21.—R.H.S. Fortnightly Meeting.

October 22. — Sheffield Chryanthemum Society.

November 6 and 7.—National Chrysanthemum Society, at Vincent Square.

GARDEN SOILS AND THEIR TREATMENT

A USEFUL ARTICLE ON HOW TO WORK DIFFERENT GARDEN SOILS. MANY OF OUR READERS EXPERIENCE DIFFICULTIES WITH AN ABNORMAL SOIL, AND THIS ARTICLE HAS BEEN WRITTEN TO HELP THEM.

GARDEN soils may be considered from many different standpoints, but in deciding upon the method of treating them to increase their productivity some special reference must first of all be made to the question of their porosity or otherwise. I always divide them into three distinct groups which are as under:

(*a*) Those which are impervious or practically so.
(*b*) Those which are semi-pervious, and
(*c*) Those which are very porous.

The object one aims at in treating garden soils is to bring them all within the second group. Soils which are semi-porous, and therefore more or less pervious to moisture invariably prove more satisfactory as mediums for growing flowers, fruit and vegetables in, than do soils which rain runs off, or which, on the other hand, are so porous that they dry up a few hours after a thunder-storm.

These three groups of soils comprise many other classes of soils, and it will be convenient in the present article to consider six of these last individually. Those which are impervious include heavy clays and chalk marls, those of the second group consist of the medium loams and manure-sick land, while the porous group contains only those soils which are termed calcareous sand or very light sand indeed.

Heavy clay soils may be regarded as practically impervious to moisture. In the worst examples rain runs off the surface, leaving this soft and sticky, but failing to reach the roots of one's plants. While such soils keep moist much longer than any others, if they once get dry, the difficulty of thoroughly moistening them again is enormous, as will be apparent. Strong clay loams, a kind of intermediate class, are not quite so troublesome to work. These will let a reasonable amount of moisture pass through to the roots, although in many cases this is barely sufficient. The working of these soils, however, is a costly matter, although ultimately they can be got into a state of high productivity.

The first thing that must be done, therefore, with heavy clays is to improve their texture mechanically. Their impervious character can be reduced and in consequence the porosity increased by working in coarse materials both of a mineral and a vegetable or animal character. Thus, ashes prove exceedingly valuable if dug into strong clays, provided that they are used only in reasonable amounts and that the ashes are well sifted, while strawy stable dung and half rotted vegetable refuse, even of a semi-woody character, do wonders if worked in. Ordinary digging, however, is quite insufficient, and trenching to the depth of a yard, although an exceedingly expensive operation, will undoubtedly pay for itself in the end. Where true trenching cannot be carried out, thorough bastard trenching of the ground will be the only alternative, and care should be taken to mix whatever manure is used thoroughly with the lumps of clay. The surface of such soils should be left as rough as possible, and work started at the earliest moment, so that the frost can get into the clods and break them down.

There is also a chemical way of treating these impervious soils, this applying more to the heavy clays than to the chalk marls. Quicklime, if worked in during the trenching operations, will combine with the clay and liberate potash, breaking down the soil in doing so. Heavy liming for several years in succession will do wonders to increase the productivity of such soils. With regard to those which are already chalky it will be wise to follow up the liming by the use of acid fertilisers as stimulants, otherwise such soils may become too alkaline in character to suit the majority of flowers and vegetables.

As regards soils of the second group, *i.e.*, those which are semi-pervious, I need hardly devote a great amount of space to the treatment required by medium loams, as it is well known that these soils can be kept in their present high state of fertility by the generous use of organic manures, either animal or vegetable, every season, supplemented by the application of suitable artificial stimulants from time to time. The only warning that I would give with regard to this class of soil is that it may become either too acid or too alkaline by the over-application of such artificials. Care should be taken to avoid this, as otherwise the fertility will be reduced. If the custom is to use acid stimulants, such as sulphate of ammonia and superphosphate of lime, periodic liming will be essential; while if the gardener, on the other hand, is fond of applying basic slag, basic superphosphate, cyanide and so forth, all of which tend to increase the alkalinity of such soils, the periodic use of some of the well known acid stimulants will be equally essential to keep the soil in a normal condition.

Those soils, however, which are manure sick, and which are almost invariably of a medium character, require special comment, as it is waste of time and money sowing and planting them without first attending to their condition. Manure sickness may be due to many things. First of all to undue generosity in the application of organic manures such as stable dung and vegetable refuse; secondly, to the over-use of artificials; and thirdly, to the accidental application of some material either poisonous in itself or containing some definitely poisonous constituent.

The first step in the right direction is to give up manuring such soils with dung or vegetable refuse for a season to see how this acts. In many cases if this is done such soils at once become productive. For those upon which it is suspected that too much chemical material has been applied, the same advice holds good. No chemicals of any kind should be used for a season or two, and this will frequently bring these soils to productivity again, or conversely, the use of some artificial of an entirely opposite chemical character, *e.g.*, an acid salt like superphosphate instead of a basic material such as basic slag, may do the same.

Soils which have been poisoned can almost invariably be saved by heavy liming. This mode of treatment can be resorted to in the case of those subgroups just mentioned, but I never advise it unless absolutely essential, as heavy liming is exceedingly destructive of plant food, and very often unnecessarily so. Soils nowadays can be poisoned in a variety of ways, but the chief danger is iron poisoning, due to the use of fertilisers containing iron as "intensifiers." There is nothing for it in such cases but to use quick lime at the rate of half a pound or even a pound per square yard, forking it in immediately, and risking the destructive effect it has on the contained humus.

We now come to the third group, *i.e.*, those soils which are porous, and some which are very porous indeed. The first class in this group includes those soils which are best described as calcareous sands. They are light in character, though not unduly so, and contain a very fair though not too generous an amount of chalky or other calcareous material. Nearly always these soils are very poor in humus, hence one method of treatment is obvious to the gardener. Such added humus, however, will not wholly bring this soil into a high state of fertility, or only after an exceedingly long period has elapsed.

No lime of any description must ever be applied during the treatment of this kind of ground. If it is, the soil will fall back as regards fertility instead of this being increased. What is known as the "acid" treatment must be adopted in every instance, and this consists of dosing the soil both in winter and summer with artificials of an acid character, which will slowly but surely rob the land of its excess of lime. For summer use, nitrate of soda or sulphate of ammonia, ordinary super-phosphate and a variety of other materials can be used with great advantage, while in the early winter a material known as double superphosphate can be applied at the rate of an ounce or even more per square yard. A certain amount of this is sure to be wasted—it is unavoidable—but in being washed through the soil it will act on the lime contained and reduce this amount to an appreciable extent. Acid sodium phosphate has been recommended with a similar object in view, and although this is much more costly than the other, it is said to be remarkably useful for improving the fertility of such land.

We are now left with light sandy land to consider, and this is the most troublesome and expensive of all to improve

Digitized by Google

as regards fertility. It is not hopeless, however, as many gardeners imagine, but it may take a long period of years to attain the object in view.

Very light sandy land is invariably poor, and cartload after cartload of dung or vegetable manure can be dug into it without making any appreciable difference. This is due to the fact that the humus supplied is immediately washed through the soil and into the subsoil on account of the excessive porosity. What we want to do, therefore, if waste is to be avoided as regards manure, is to improve the mechanical condition before adding humus, and then there is reasonable hope that such manure as is used will be held.

With this object in view an application of clay or chalk marl is recommended if it is possible to obtain it. These materials are spread on the surface in lumps at the rate of one hundredweight per square rod or even more if possible. Early autumn application is absolutely essential, as these lumps of material are only very slowly acted upon by the frost and broken down into a coarse powder which can be worked in. It will be necessary in most cases to rake off unacted upon lumps next March, but, of course, these can be saved for use the following season.

While early application of clay or marl is so essential, manure itself should be used at the latest possible moment, *i.e.*, not now, but next spring, immediately before the land is sown or planted. Sticky, moisture-holding materials such as cow manure and pig manure give the best results, and heavy dressings must be used. The destructive action of quick lime must be avoided on such sandy soils which are sour by using chalk or ground limestone, and a pound per square yard will be perfectly safe. Generally speaking basic fertilisers should be avoided, unless such diseases as clubroot of cabbages make their appearance. E. T. ELLIS.

CORRESPONDENCE

A CORNISH VINERY NEAR PENZANCE.

SIR,—This illustration of a vinery in Cornwall may prove of interest to your readers. This vine is over 100ft. long and one of the largest

ONE OF THE LARGEST VINES IN OLD ENGLAND.

in England. It carries a prolific crop of grapes, necessitating extensive propping of the vine. It shows what can be done under careful and attentive cultivation.—T. E. CORIN, *Penzance*.

KNOT GARDENS.

SIR,—As the writer of the article on this subject in THE GARDEN of September 6th, I am naturally greatly interested in the information given by your correspondent "J. H. H." in the issue of October 4th regarding "fea-berries" and "raisins." On the evidence he supplies it seems impossible to doubt that the first mentioned were really gooseberries, yet it is difficult to understand how they could have been used satisfactorily as an edging for the invariably small beds which made up a knot garden. Rea speaks of designing a draught of twenty-three divisions "each to be two feet six inches broad, then the Fret will be nineteen yards six inches square," and these dimensions may be taken, I think, as average ones. For these little "knots" deciduous bushes such as gooseberries seem strangely unsuitable as a bordering, and the drastic clipping absolutely necessary if there were to be any room left in the beds for plants would nullify any hope of fruit. Much the same objections would apply to ribes, but grape vines might possibly be trained on low trellises, and these may be the 'raisins" referred to, as your correspondent suggests. Clarity of description, however, was not the strong point of the old-time writers on gardening, and their works abound in problems which the modern horticulturist finds hard to solve!—R. E. HEAD, *Somerset*.

TOMATO CULTURE.

SIR,—I was much interested in the illustration and note on growing tomatoes on a roof, page 688, issue October 4th. It is surprising how much an enthusiast will do in adverse circumstances. Mr. House, a business gentleman in Bournemouth, has grown some very fine crops of tomatoes on a large roof over shops with low walls as retainers. Also, he possesses a very charming greenhouse on the same roof and garden frames. In the latter he grows violets, mustard and cress, radishes and other crops, and in the greenhouse roses and tree carnations. The last named are his favourite flowers and, judging from the condition of the plants and their large well coloured blooms, he knows how to treat them. Such enthusiasts deserve real large gardens.—G. G.

THE SCARLET PIMPERNEL.

SIR,—I have been very interested to read on page 669 that "H. P. M." has been growing the scarlet pimpernel as a border plant. For many years I have grown the blue pimpernel in a similar way. This is not a very common flower. It flowers as profusely as the scarlet, while its flowers are cornflower blue. Alas! I fear I have lost it in a recent move, for none of the seed I brought with me germinated. As compensation I have discovered in my newly made garden a large plant of wine-coloured pimpernel which I have never seen before. It has flowered well and is covered with seed. It is a colour which would tone well with magenta and grey, and if "H. P. M." would care to send me his address I would be delighted to send him some seed to experiment with. May I say what great pleasure and interest I find weekly in THE GARDEN. Many thanks for the great trouble which must go to its production.—(Mrs.) GWENDOLYN ANLEY, *St. George's, Wych Hill Lane, Woking*.

BULBS IN POTS.

SIR,—At this season when everyone is concerned with the planting of bulbs, I venture to tell you of a method I have employed for many years with unfailing success for indoor culture. The bowls I have used are those made by Messrs. Harris and Son at their potteries at Wrecclesham, Farnham, and sold by Messrs. Liberty and Co. The bulbs are grown in moss gathered from the hedges (*never* moss fibre) and preferably the fern-like moss. A good layer of moss is put in the bottom of the bowl and the bulbs put in closely, ten to twelve bulbs into each bowl (according to the size of the bulbs and the bowl). The moss is "tucked" closely and firmly round, and pressed down tight. No charcoal is used. The bowls are kept in a cool dark cupboard until the roots are formed (two to three weeks) and then brought out on the sitting-room window-sills. The amount of water required depends (1) on the weather and the amount of sunlight, (2) on the heat of the room in which they are kept. My bulbs have always flowered well and kept the house gay for months, and been the admiration of everyone, including the people who have greenhouses and skilled gardeners. The kinds which I find most successful are: Daffodils Golden Spur and Princeps, Narcissus Barrii Conspicuus, Roman hyacinths, Scilla sibirica and purple crocus (yellow are not so good). Tulips do *not* do well—I think they require soil.—M. M. S., *Bath*.

HEALTH AMONG THE CHRYSANTHEMUMS

THE chrysanthemum habitually puts up with a great deal of mismanagement and neglect, without very serious consequences, during its cultivation by many amateurs. Nevertheless, it is true that it has quite a large number of enemies, both insect and fungoid, to which it not infrequently succumbs: also that these enemies may be dealt with satisfactorily and kept under control in the majority of cases.

Perhaps the greatest cause of disease is due to attacks of many fungi. Oidium chrysanthemi, the chrysanthemum mildew, is especially prevalent where an attempt is made to grow more plants than the houses will properly accommodate. It has the appearance of a thin, whitish powder dusted over the leaves, and it should not be confused with the bloom on the young growth of every healthy chrysanthemum. To guard against it the plants should be kept equally free from coddling and cold winds, and in case of infection may be sprayed with a solution of sulphide of potassium.

A more uncommon disease is that caused by the fungus sclerotinia. This is to be noticed first as a white mould or mycelium, which penetrates the stem and ultimately gives rise to numerous black spores within it. In the later stages the treatment recommended is destruction of the plants by burning. Spraying or covering with slaked lime has also been found to be quite effective in controlling this disease.

Puccinia chrysanthemi, one of the rust fungi, is the cause of the rusty or light orange-coloured spots which are so common an occurrence on the leaves of the chrysanthemums. It is a fungus which spreads rapidly, owing to its possession of two sets of spores: the summer spores, rusty brown in colour, which carry on infection over the summer, and the winter spores, which do not germinate till spring. All infected leaves should be burned, those remaining in the plants sprayed all over, and the soil around the plants soaked with a solution of sulphide of potassium.

A dark red-brown spot sometimes found on the leaves is not so dangerous, but may receive the same treatment. It is caused by Septoria chrysanthemi.

The leaves and flowers of the chrysanthemum provide food or recreation for a considerable number of small creatures, to the detriment of the plant both in appearance and health. Aphides are probably the chief offenders and are most troublesome to deal with, owing to their small size and rapid powers of reproduction. If only a small number of these creatures are noticed, whether on leaf, bud or blossom, very thorough measures should be taken at once. For leaves an emulsion of soft soap and tobacco with the addition of a little paraffin (say half a wineglassful to a gallon and a half of emulsion) may be sprayed on the under and upper surfaces of the leaves, or powdered tobacco or pyrethrum may be used with a bellows sold for that purpose. For flowers the latter method only is suitable, and should be carried out with care, so as not to disfigure the flowers. Syringing very thoroughly with water may be successful, but requires constant repetition. If ants' nests be in the immediate neighbourhood, it may be well to give the plants repeated dressings with the above emulsion or some tried insecticide, as well as any treatment of the soil thought desirable, as the ant cultivates the aphis for its own purposes, placing out individuals on plants which give promise of being suitable for new aphis colonies, and keeping an eye to their welfare. So that if the aphis is not wanted the ant should be eliminated, apart from any damage that he may himself carry out.

A strong pocket magnifying glass will be found useful in observing the diseases of plants.

Some leaves may be found showing areas of a lighter colour. These are caused by a small leaf-mining maggot which turns into a blackish chrysalis and then into a fly, which should be destroyed before it has time to lay eggs and start the trouble over again. The species illustrated, known as Phytomza affinis, is one of the commoner kinds. Such leaf-miners need double treatment. Leaves which show signs of "paths" should be picked off and burned, or dropped into an insecticide, and the plants from which they are picked syringed at frequent intervals by a well mixed wash of a wineglassful of paraffin to a gallon and a half of water, to render the leaves obnoxious to the fly. Indoor plants should have a weekly fumigation while the fly is about. The writer wishes to thank Mr. J. B. Wroe for information on several points from his useful handbook.

If an insect be seen to carry a stiff-looking beak, it may probably belong to some species of sap-sucker, and from the gardener's point of view it would be better dead. Of these, frog-hoppers are most conspicuous; but other green or brown "bugs" may be found which weaken the plants considerably by sucking the sap through their sharp beaks and causing distortion of the young leaves and sometimes injury of the buds. Some species are said to live on aphides and other insects, but unless a gardener is something of an entomologist, it may be well to pick off and destroy all such visitors. They may frequently be found on young leaves near the terminal buds.

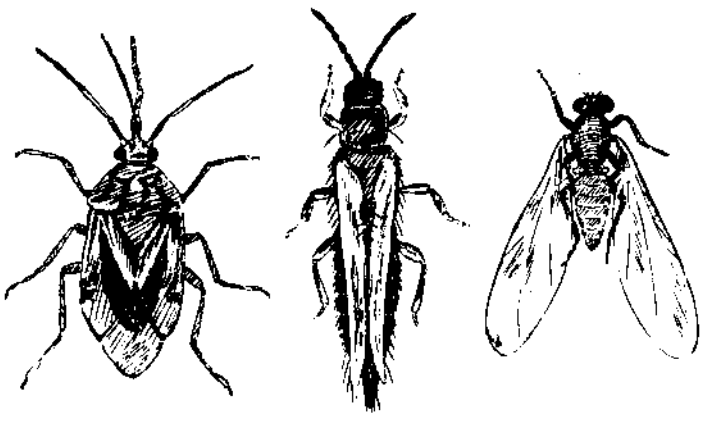
THE SO-CALLED "PATHS" OF THE LEAF-MINING MAGGOT.

Lygus pratensis is said by Mr. Lang to be one of the greatest offenders, but there are others. A brown species, frog-like in shape, with a short beak and no antennæ, has been found on young growth with disfigured leaves and buds. A glass tube is useful in collecting these insects, and a newspaper or tray held underneath will prevent the loss of those that fall or jump to the ground when disturbed.

Buds are liable to be attacked by caterpillars and leaf-miners as well as aphides, and need watching so as to keep them perfectly and thoroughly clean before they open.

Roots may be attacked by wire-worms, which are the larvæ of the skipjack beetle and are thoroughly destructive pests. They have a brown polished skin, are about an inch long, live four or five years, and are often numerous. Therefore it is as well to treat any ground on which chrysanthemums are to be planted, or from which the soil for them is to be taken, with a dressing of gas lime, vaporite, alkali waste or kainit. If wire-worms should be found where plants cannot be disturbed, vaporite may be sown in the earth, insecticide used, weeds removed and the earth frequently stirred. Traps of carrots, etc., may be buried and frequently examined, and small heaps of leaves covered with tiles may be arranged as traps in suitable places.

Leather-jackets are the larvæ of the daddy-longlegs and are soft grubs of a greyish brown colour with a small



From left to right: (*a*) LYGUS PRATENSIS, (*b*) MINUTISSIMA, (*c*) PHYTOMZA AFFINIS.

Digitized by Google

head and a blunt end. They are exceedingly destructive to chrysanthemums as well as other plants. Where they are suspected, the earth should be examined, on and just beneath the surface, and the grubs collected and destroyed. The soil may be treated with the same remedies as for wire-worms. The daddy-longlegs itself should be caught with a net and destroyed whenever it is seen to be prevalent, which will be in early summer and autumn.

Thrips do a certain amount of harm to chrysanthemums by sucking the sap from the leaves and so lowering the health of the plants, and also by their presence impairing the speckless perfection of the flowers even when they do not actually injure them. Thrips minutissima is one among several species that gives trouble in this way. It is little more than 1-16th of an inch in length, has narrow iridescent wings covered with hairs, and to the naked eye appears to be black. Thrips are apt to abound in hot, thundery weather, and are hence often known as thunder-flies. They may be dealt with by fumigation or syringing with an insecticide.

The principal objection to using insecticides for leaf destroyers, etc., is that they may also, along with the pests, kill several kinds of larvæ that are most useful in their activities against them. Of these the most valuable is the lady-bird, whose larva, black speckled with orange, having six rather prominent legs and a pointed tail, spends all its active life in hunting and eating aphides. The hover-fly larvæ are equally voracious among aphides. They are soft and somewhat slug-like, of a green, grey or brownish tint and have a habit of holding up the aphides away from the leaf while they suck their juices.

That strange and beautiful creature, the lacewing fly, is hatched from larvæ of the same habits and is often covered with the empty skins of its victims.

If sufficient of these larvæ can be collected and placed upon plants infected with aphides they will soon clear off those most troublesome pests.

M. BROOK.

THE GARDENS AT WEMBLEY

(Continued from page 701.)

THE OVERSEAS GARDENS.

INDIA, the "Gem of the Empire," always comes first in the minds of English people, and we imagine the majority of the multitude of visitors would place India's garden first among those of the Dominions and Colonies at the Exhibition. The beautiful, fascinating India palace stands on high ground, commanding a view along the lakes to the extreme western side of the Exhibition grounds. The gardens, which are principally on the western side, were designed and controlled by Mr. A. Cecil Bartlett, the Kew landscape gardener, and they are a fitting ornament to the lovely palace. A broad, level walk flanked by flower beds gives the needed terrace effect, and from this the ground slopes pleasantly to the outer boundary, which is marked by tall, shapely cypresses alternating with more flower beds. On the slopes there are groups of palms, bamboos, various ornamental shrubs and a particularly successful large oval-shaped bed of brightly coloured maples rising above a groundwork of white marguerites, among which salmon pink gladioli have been and still are flowering freely. The bed is bordered by large plants of pelargonium King of Denmark, of which in this western aspect the abundant flowers do not burn. Along the terrace walk and in front of the Indian Theatre, bright colour, grace and fragrance are, as they should be in the garden of India, the keynote. Cannas, which were freely planted in association with other suitable plants, are flowering freely and give a very tropical effect. Many Lilium auratum and other species rise above beds of coleus and silvery centaureas. The dwarf scarlet salvia Harbinger is associated with standard Abutilon Thompsonii of rich golden colour and Lilium auratum. Free-flowering begonias of Lloydii and Major Hope type, Lobelia cardinalis, Lippia (Aloysia) citriodora, heliotropes, dwarf and standard, and plenty of brilliant scarlet Pelargonium Paul Crampel are the names of some others of the plants which help to give the floral display. Alternating with the beds on the palace side of the terrace there are many fine specimens of Arundinaria nitida, whose graceful stems give a delightful effect. These are balanced on the opposite side by equally tall examples of Bambusa aurea.

Burma's garden, like its building of wonderfully ornamented spires with tinkling bells, is of quite distinct character and is, we believe, typical of the gardens of the wealthy in that country. The principal feature is the ornamental canals, which intersect at a beautiful bridge house. These canals give to pleasant grassy slopes which, as in neighbouring India, are beautifully green and even. On the higher slopes there are quaintly shaped beds well filled with tropical plants and flowers. Ceylon, which possesses, in Peradenyia, perhaps the most beautiful garden in the world, does not seem to have "gone in" for gardening, and is chiefly noteworthy for the well built glasshouse where Messrs. L. R. Russell display their well known plants.

To the lover of uncommon plants the garden of South Africa is the most interesting in the whole of the Exhibition and it is exceedingly well kept. The principal features are the kopje, which makes a most suitable home for many native plants collected from the Karroo, and the protected rock garden adjoining the building, where may be seen many of the most curious plants of the Empire. This garden was made by Mr. Frank Frith, horticulturist to the Cape Railways, who, luckily, has remained to watch over his most interesting contribution to the Empire's botany and horticulture. Not only were the very many plants shipped over from the Cape, but, to ensure success, their native soil was also brought, with the added result that the surface now teems with an enormous variety of seedlings, many such as never before have been seen in this country. When the Exhibition closes, these succulents will go to enrich the collections at Kew, Cambridge and Edinburgh. Space will not permit the mention of a tithe of these valuable plants, but the principal genera are cotyledon, crassula, gasteria, aloe, haworthia, staphylea, euphorbia, encephalartos, sarcocolon, senecio and testudinaria; while among the bulbous plants are crinum, babiana, watsonia, brunsvigia, agapanthus and richardia, with clivias and, of course, pelargoniums.

Canada is well served with space for gardening, and around the Canadian Pacific Railway's building Mr. H. Hemsley has made a very attractive garden. Conifers, such as Douglas firs, pines and golden yews, enter into the scheme, and there are well filled beds of roses, pelargoniums, marguerites and other plants set in ample greensward. Beyond there are similar conifers to those already mentioned and large beds of scarlet pelargoniums.

The tree ferns of Australia immediately attract the visitor's attention. A great many dormant stems, 5ft. or so in height, were sent over last year to Messrs. L. R. Russell, Limited, who are responsible for Australia's garden. These were started into growth at their nursery, and in due season stood along the front of the building as specimen plants. The many flower beds contain an agreeable variety of plants. Plumbago capensis, tall centaureas, tobaccos, maize, pentstemons and others all play their part in the scheme. While there is a very complete collection of fuchsias and, at the western entrance, large beds of Pelargonium Paul Crampel provide brilliant masses of colour.

Malaya has a magnificent pair of chamærops palms with smaller specimens of phœnix and such, but had no opportunity of outside gardening. New Zealand contented itself generally with several beds of rhododendrons in the spring, a row of Club Palm (Cordyline australis), Eucalyptus Globulus, small native plants and a few beds of summer-flowering plants, with ample green slopes.

In the eastern section the largest and most important colonial garden is that of the West Indies, which was designed by Mr. A. Cecil Bartlett. The various flower beds of Begonia semperflorens rosea and tall Abutilon Thompsonii, and dwarf blue ageratum, which is largely grown in the islands, browallias, plumbago, roses and antirrhinums, have all been planted to good effect. One very successful bed was of Galtonia candicans rising above pink antirrhinums. Palms are an important feature of the garden.

WINDOW PLANTS IN WINTER.

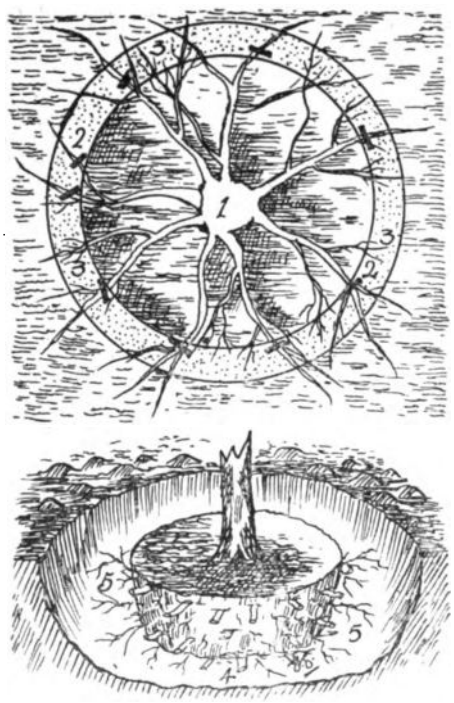
WHEN one has grown flowering and foliage plants in one's windows during the summer months one wishes to keep the latter gay and interesting throughout the winter months too. The task is not really a difficult one, as there are both plants and bulbs to select from. To be successful in growing plants and flowers in dull, sunless days, much will depend upon the arrangement: there should be more room allowed for the plants to grow in. Of course, in dealing with window gardening, window boxes outside must be taken into account. Do not wait until all the summer-flowering plants have faded before re-filling with the winter ones, as it is very important that the plants have a chance to form new roots and thus take possession of the soil before the very cold weather comes. Where it is possible take out all the old soil and replace with fresh—loam, leaf-soil, sand, a little well rotted manure or a small quantity of bone-meal. A compost of this kind will enable the plants to flower freely in early spring. As regards pot plants, it is advisable not to re-pot now any more than is absolutely necessary. Furthermore, the drainage of each one should be made perfect. The following are a few suitable plants: Abutilons, begonias, chrysanthemums, cinerarias, primulas, Echeveria retusa, Eupatorium riparium, zonal pelargoniums and cool greenhouse ferns, as well as bulbs. The latter, too, in window boxes with wallflowers, myosotis, arabis, aubrietia, polyanthus and daisies.

POTTING SOILS: TREATMENT OF THE TURVES.

The successful cultivator of greenhouse plants, and, in fact, many others grown in boxes, pans and borders restricted in size, must have a good stock of loam of a fibrous nature to form the base of nearly all composts. Such turves should be cut and stacked now. It is very interesting work, though, perhaps, backaching sometimes if the turves are wheeled a considerable distance. But the enthusiast is not conscious of a backache: he only sees the sturdy chrysanthemum plants he intends to grow next year, the lovely curled-back "grass" on the carnations, the massive cinerarias and healthy specimens of many other kinds, including rock and border plants. Wireworms are mostly found in the top 3ins. of grass land; examine the turves closely for these pests before stacking the turves, and destroy all found. Cut off any long grass first; that which has been grazed closely by animals—even rabbits—is the best; it cannot contain too much fibrous matter. Stack the turves, grass side downwards, with a layer of rotted manure and a light sprinkling of fresh lime between each layer. Tread down each layer as it is placed in position. Form a sharp-angled roof to the heap to prevent rain-water percolating through. A heap of this kind will be matured for use, for many kinds of plants, three months after stacking; for choice subjects five months hence.

ROOT PRUNING FRUIT TREES.

Apples, pears and plums, with peaches and nectarines, the latter both under glass and outside, chiefly, come under this heading. Frequently, trees not



bearing fruit satisfactorily are root-pruned and brought into a fruitful condition. The work is best done in October. An experienced cultivator may, with safety to the trees, cut off roots all round in one year, but I advise the inexperienced to cut them half round one year and half the following autumn. A tree about seven years old should have a trench taken out 2ft. 6ins. from the stem, the trench being about 16ins. wide. These distances will serve as a guide. Only cut off the strongest fibreless roots. No. 1, tree stem; Nos. 2, 2, roots, with dark lines across to be cut; Nos. 3, 3, 3, roots, finer, more fibrous, to be retained. Work under and cut off the tap root, too, placing the cut end, No. 4, as shown; Nos. 5, 5, fibrous roots retained. Fill up the trench with good loam and make it firm.

OUTDOOR CLIMBING PLANTS.

Some of these are now presenting a straggly, untidy appearance and calling for the attention of the gardener. The latter, who understands them, can see beauty in those long branches, some of which are beaten to and fro by the winds, and he knows that timely attention now will result in added beauty next year. It is well to note whether the plants have filled their allotted space and, if so, to restrict growth accordingly, and this may be done by cutting out, judiciously, some of the longest shoots so that the shorter ones can be trained in. If the space is not filled, retain all young shoots, provided they will not be overcrowded. Evergreen climbers at all times show overcrowding very plainly, but the deciduous ones appear to be all right now, but not when they are bearing leaves. These facts should be taken into consideration at the present time. There are several purposes for which climbers may be planted; some to form a screen, some for their beautiful foliage mainly, others to furnish old buildings, walls, fences, arches, pergolas and pillars; and, as the planting season is coming, the plants should be purchased so that each one will be suitable for the position selected. Clematises like a rich, loamy rooting medium with a small quantity of leaf-soil and rotted manure. Roses thrive in a more retentive soil, and for other climbers generally a medium heavy loam will be suitable. Now is a good time to prepare all the borders.

PARSLEY.

We miss flowers in the winter time when provision for a supply of them has not been made. We also miss parsley leaves when they are not duly provided. The July sowings generally provide the winter crop, but it is a difficult matter to induce the plants to grow in some soils. In very heavy soils, and especially during the recent long spell of wet weather, plants of parsley make poor growth and the leaves turn yellow, very disappointing when we look for those nice deep green ones so appreciated. With a view to helping cultivators who are now disappointed with their crops, I suggest that they construct a raised border in a sunny position—where clayey soils obtain—and mix some old mortar rubble with the top 6ins. Failing mortar rubble use ordinary gravel and stones freely, but not ashes nor cinders, as parsley grown in such a rooting medium often cankers badly. The young plants should be lifted with roots intact and replanted carefully in the new border or cold make-shift frame. Allow a space of 1ft. all ways between the plants.

GEORGE GARNER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Asparagus Beds.—Directly the foliage is ripe it can be cut off, all weeds removed, and the beds made clean and tidy. A dressing of partly decayed manure should be afforded, not forgetting the outside or slopes of the beds where the roots and crowns are often more or less exposed to the weather.

Globe Artichokes.—Plants left in the beds will need a little protection during the winter months, and now they have died down the crowns may be surrounded with ashes or straw litter.

THE FLOWER GARDEN.

Roses.—During the next few weeks any alterations in the rose garden may be carried out, and the replacing of worn-out trees by newer and improved varieties. New beds ought to be trenched or dug two spits deep, and a layer of decayed manure will eventually be beneficial if placed sufficiently deep so as not to come in contact at once with roots of the trees. Select strong-growing varieties with good foliage, they thrive better and are less susceptible to mildew.

Storing Tuberous Plants.—Such plants as begonias, Lobelia cardinalis, dahlias, cannas and Salvia patens are best lifted for the winter and stored in a frost-proof shed or cellar. Keep the roots fairly dry.

Lawns.—Leaves are falling rapidly, and they should be collected at frequent intervals to prevent the ruin of the grass. When the mowing is finished for the season, the machines should be cleaned, and coated with oil before putting them away for the winter.

THE HARDY FRUIT GARDEN.

Cuttings.—Bush fruit, such as white red and black currants and gooseberries, are increased by means of cuttings, which can be prepared at this season. Choose well ripened shoots, which should be about 18in. in length. Make a clean cut at a joint, and remove the lower buds of gooseberries, red and white currants to secure a clean stem; but with black currants the basal buds are left intact. The cuttings should be inserted in lines 1ft. apart, and in depth about one-third of their length. They should be quite perpendicular, or the result will be a badly shaped plant. A little sharp sand will be an advantage to assist in the formation of roots. Although now is a good time to propagate these fruits, such work can be continued during the next few weeks. In the meantime the cuttings may be tied in bundles and their heels laid in soil or ashes until an opportunity occurs for planting. Protection from birds is essential, or loss of buds may result. When securing a new stock of black currants, the variety September Black should be given a trial.

Loganberries and allied fruits can also be increased by cuttings, while layering of the growths is also recommended.

Staking and Tying Trees.—Where trees have already been staked in previous seasons, it will now be necessary to examine them, and if required new stakes and ties must be given to prevent disaster during the autumn gales.

FRUITS UNDER GLASS.

Late Peach House.—In this house all the sunlight and air possible should be admitted to secure the thorough ripening of the wood. Until the foliage is ripe the trees may be syringed daily to keep in check insect pests; at the same time see that the roots do not suffer from lack of moisture.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Asparagus.—As soon as the stems have browned and withered they should be cut over and, together with all weeds, cleared from the ground. A mulch of good farmyard manure should then be spread over each bed as a top-dressing.

French Beans.—These have not done quite so well this year. The plants were slow to make headway, hence they were late in flowering and producing pods. The wild winds, too, which were experienced later tossed the plants about, doing much damage to the foliage. All spent plants or those destroyed by frost should be cleared from the ground.

Rhubarb.—There is no doubt a good dressing placed around and over the ground between the crowns has a marked effect upon the rhubarb supply. Even if no farmyard manure can be spared, leaf-mould will provide good feeding material for the roots. This covering should be spread over as soon as the leaves and stalks have died down and all have been cleared away.

THE FLOWER GARDEN.

Bedding Begonias.—Young plants raised from seed sown in the early part of the year, and which were pricked off and grown in frames, should be lifted now, the small corms placed in cutting boxes and treated similarly to those which have been used in the flower-beds.

Dahlias.—The tubers of these plants and also of Salvia patens should be taken up from the borders and stored in a shed or other outhouse where they will be quite safe from frost. Any soil which clings to the roots and tubers may be left thereon until it dries up under storage. Where a number of varieties are grown and require to be kept distinct the tubers should be placed in boxes and the name of the variety securely fixed to each box. Gladioli corms should also be lifted, then tied in bunches labelled, and hung from the rafters in an airy shed.

Lilies.—In time the panther or pardalinum lilies become so crowded that they do not give of their best, therefore those having beds in a crowded state should have the withered stems cleared away and the bulbs lifted. The beds should be deeply dug or trenched, with farmyard manure or leaf-mould incorporated as the work proceeds. The largest and best bulbs should then be selected and planted 5ins. or 6ins. deep and 9ins. apart.

Irises.—The bulbous section—like lilies—also get into crowded groups and so require to be taken up and separated, then replanted so soon as the beds or stations have been dug and enriched with fresh loam or old manure. The bulbs should be set 2ins. or 3ins. deep and about 4ins. apart.

THE HARDY FRUIT GARDEN.

Grease banding.—We are reminded that the wingless females of the winter moths ascend the fruit trees about this period of the year, and if some kind of material smeared in grease is tied so as to form a band round the stem of each tree it will prevent the moths from reaching the branches above and from obtaining places in which to deposit their eggs. The grease or other sticky material used should be renewed occasionally throughout the winter.

Fruit Bushes.—Any worn-out or useless plantations of gooseberries, black, red or white currants, should be cut down now and consigned to the flames. Later on the ground should be thoroughly trenched and manured.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.).
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Bouvardias, which are so useful for winter flowering, will stand in an ordinary greenhouse where a temperature of about 45° to 50° can be maintained; but where they are grown for a supply of cut flowers they are better kept a little warmer if a regular supply is to be kept up. Where they have been planted out for the summer they may be placed in suitable-sized pots, or else planted out in a raised bed in a low pit. They are very subject to attacks of white fly and begonia mite. The latter is easily prevented by the use of the sulphur vaporiser and the former by the use of some approved remedy or fumigating with hydrocyanic acid gas. Bouvardias are so beautiful and useful that it is surprising they are not more generally grown.

Anchusa Italica var. Dropmore is very useful for the cool greenhouse during the spring. Good strong plants should now be lifted and placed in pots. Three or four plants may be placed in an 8in. or 10in. pot. The plants may be stood in a cold frame or may be stood outdoors at the bottom of a sheltered wall, plunging the pots to the rim in ashes. The varieties Opal and Pride of Dover are equally useful for the same purpose.

Veronica speciosa, of which there are many fine varieties, is very useful for the greenhouse during the autumn months. If cuttings are put in during this month, they will make fine plants for next year; they root readily in a close case in a cool house. Young plants raised from cuttings last year have been in flower for some time now, and if so desired can be grown on for next year, when they will make fine large specimens, which are very useful for standing in the conservatory beds. As they are more or less hardy in the south and west, they only require the shelter of a cold frame during the winter months, while during the summer they are best stood out in the open on a clean ash bottom. If they are pinched several times during the growing season they make fine bushy plants.

Lily of the Valley is always popular for greenhouse decoration and for cutting during the winter and spring months. Where required for Christmas flowering strong crowns should now be potted up. Twelve to eighteen crowns may be placed in a 48-sized pot. After potting they should be stood outdoors in an open position, plunging the pots to the rims in a bed of ashes, all hardy herbaceous plants forcing more readily after the crowns have for some time been freely exposed to the weather. If required for Christmas, about six weeks should be allowed for ordinary crowns. If retarded crowns are used, they will respond more readily to forcing. For a hardy plant lily of the valley will stand unusually high temperatures. When forcing they should be plunged in a case with a temperature of 75° to 80°, but with such high temperatures care should be taken to put a little air on the cases during the night. If this is neglected, a rise in temperature may result in the crowns being scalded. Where large quantities are required, the crowns may be packed into boxes. Where the supply is home grown it may be lifted in turfs and placed in boxes. By this method one is always sure of a good supply of foliage to go with the flowers. Where the supply is home grown a fresh bed or beds—according to requirements—should be put down every year. With good cultivation home-grown crowns are just as good as imported.

J. COUTTS.
Royal Botanic Gardens, Kew.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Herbaceous Phloxes (A. C. B.).—The spikes sent for inspection are attacked by stem rust about 6ins. from the top of each. The sap vessels are contracted and the rust fungus affects the pith of the stem, first causing abnormal swelling and then total destruction of pith stem and leaves. The recent weather conditions, combined with too much moisture at the roots and the cold, have caused the rust to spread on the more tender varieties. It has occurred in similar seasons before. Cut off the tops only of all affected plants and burn them. Lift the roots in due course, divide them and replant in fresh soil deeply dug, enriched with manure and a free dusting of wood ashes and bits of charcoal.

Hibiscus syriacus, Rabbits and Fungi (C. G. L.).—Hibiscus syriacus should flower freely every year in your district if the plants are grown in a poor soil; nothing more is required. It is not desirable to spray plants to prevent rabbits eating them, as such spraying, to be effectual, would damage the plants. Fresh tarred twine, fastened to small sticks about 6ins. above the ground and encircling tree stems or borders, will usually deter rabbits. We do not know of any process whereby fungi can be sprayed with a view to its preservation. It can be so preserved in alcoholic spirit placed in air-tight bottles.

TREES AND SHRUBS.

Curious Growths on Oak Tree (G. J., Bridgwater).—These peculiar growths on the twigs of oak which you sent in for inspection are known as artichoke galls, resembling very much a hop flower with imbricated scales. At first it is of a green colour, but becomes brown with age. The real gall is a small acorn-shaped body within these scales. It is caused by an insect known as Aphilotrix fecundatrix. Gall formation is the result of contact with special cells and it follows that the insect deposits its eggs with the greatest exactitude. The two important factors at work in connection with gall formation are the activity of the vegetable sap on the one hand and the influence of stimulus due to animal agency on the other. The whole question is a difficult one. There are a great many different forms of galls on the oak caused by a number of hymenopterous insects.

FRUITS UNDER GLASS.

Treatment of Orange Trees (A. P.).—The most suitable compost for orange trees, whether in a border or tubs, is one made up as follows: Good fibrous loam, one-half; leaf-soil, old cow manure and sandy soil similar to that found in heath land, in equal proportions, one-half. Thorough drainage is essential, also plentiful supplies of water, especially in the growing stage. A close, adhesive soil, alone, such as you have used, is not suitable. The compost should be lumpy and porous. The trees like exposure, through ventilators, to night air when there is no frost. A night temperature ranging near 50° Fahr. is suitable from autumn to spring.

FRUIT GARDEN.

Harvesting of Pears (E. M. H.).—We think the pears are as follows: No. 1, probably Beurré Claireau; is usually ready for picking by the fourth week in September and will keep until the end of November, in a good store; the single fruit sent is on the small side for this variety. No. 2 is probably Calebasse Bosc; the fruit is malformed and not quite typical; does not keep well, and is but a second-rate kind at its best. No. 3, Winter Nelis, a good late pear, keeping until well after Christmas; will usually hang until the first week in October with advantage. All the fruits are rather poor specimens of their kinds. With regard to harvesting, all should be picked just as they become ripe—a little before rather than later—and during the next week or so should be tested for ripeness fairly frequently. The test is to take the pear in the hand and raise it gently to a horizontal position If it parts from the tree readily it is right for harvesting, but if any tugging or pulling is required it is best left for a while. All the pears on a tree may not be right for gathering on the same day, and only those that come away easily when so lifted should be gathered. Whether or not they are harvested at the right time has great bearing upon their keeping qualities, and only by frequently testing as advised can the work be successful. The actual date when ready varies with the seasons.

MISCELLANEOUS.

Various Questions (Miss D. R.).—Plant the bulbs in a naturally warm, dry border forthwith, cover them with ordinary soil 2ins. deep above the crowns after placing a handful of dry sand around each bulb. Do not apply water. The best leaves of the sorrel plant are those from one year old plants. Good light soil is suitable. Now is a good time to transplant to fresh ground. In spring the flower stems will grow but should be pinched out regularly, or, if left, to develop, the leaves would be very small. It is quite possible that the aster plants referred to grow from seeds sown broadcast in the border where you saw the plants in bloom. Direct sowing in the border often proves more successful than sowing in boxes and transplanting resultant seedlings.

Wild Garden Planning (E. F. W.).—Books dealing with this subject usually deal almost exclusively with herbaceous perennials. One such is "The Book of the Wild Garden," by S. W. Fitzherbert.

Goldfish Changing Colour (A. B. B.).—Goldfish are all descended from a greyish-green carp, and they have a strong tendency to revert to their ancestral colour. The gold fish were originally artificially produced from golden varieties. In a brood of goldfish bred at the Zoological Gardens some time ago from brilliantly coloured fish, a large percentage never obtained the golden colour, but remained greyish-green. At birth the fish are always greyish-green and it is only when some months old that they obtain a golden colour.

What is a Wardian Case? (A. O.).—A Wardian case is a movable frame with glass roof and sides. It is practically air-tight, but the top opens so that air can be admitted to remove excess of condensation from the glass. It was invented by N. B. Ward, who described it in a pamphlet "On the Growth of Plants in Closely Glazed Cases," 1842. Such cases maintain fairly uniform conditions of moisture and atmosphere throughout a long voyage and the plants require no watering.

Unsuitable Water for Plants (T. A. M.).—You cannot do more than you have already done regarding the treatment of water in bulk. As the district, Windermere, is a rainy one, some effort should be made to collect as much rain-water in tanks or cement cisterns as possible, for the benefit of pot and choice plants, as the rain falls so that it shall not be contaminated by soakage into the peaty soil. Simple arrangements would be sufficient. Water that must be used from the soil, stagnant water, etc., would be much improved by the addition of a pint of ammoniacal water, obtained from the gas works, mixed with sixty or seventy gallons of the water several hours before such water is applied to plants. Mix 1 peck of agricultural salt with, approximately, six barrow-loads of the leaves, mowings, etc., and turn the heap several times before the materials are used as a manure. Half a bushel of lime per 40 sq. yds. would be a suitable dressing for the ground.

Names of Fruit.—A. B.—We think the apples and pears are as follows:—1 Beurré d'Amanlis; 2, Doyenne du Comice; 3, Gascoyne's Scarlet; 4, Allington Pippin; 5, Wellington (syn. Dummelow's Seedling); 6, Allington Pippin; 7, Wellington; 8, Possibly Wealthy, but too bruised and discolored to say for certain; 9, Possibly Dutch Mignonne; 10, Allington Pippin; 11, Cox's Orange Pippin; 12, Yorkshire Beauty.—S. T.—We think the fruits are as follows:—1, Hawthornden; 2, Cannot identify from sample sent, which was much squashed; 3, Claygate Pearmain; 4, Probably Maréchal de la Cour, but malformed; 5, Summer fruits of Nec Plus Meuris; Calville Rouge d'Hiver. The No. 5 apple from the wall tree is we think, Winter Majetin.——G. S. L.—Asters: 1, Aster Novæ Angliæ var. pulchellus; 2, Aster Novæ Angliæ var.; 3, Aster cordifolius. Grasses: 1, Dactylis glomerata variegata; 2, Festuca glauca. Shrubs: 1, Cornus albus; 2, Muehlenbeckia axillaris. Apples: 1, The large red apple is Bietigheimer Red; 2, The green apple is Wellington (syn. Dummelow's Seedling); 3, The orange red apple is Duchess Favourite. Fuchsias: 1 and 2, Fuchsia macrostemma vars.; 3, Fuchsia macrostemma gracilis; 4, Fuchsia, macrostemma gracilis variegata; 5, Fuchsia macrostemma globosa.

Names of Plants.—R. S.—The chrysanthemum bloom sent is one of the various sports from Madame Marie Masse and is known in the South as Pink Masse. It may be known under another name in Scotland where the variety Madame Marie Masse is continually sporting to different shades.——N. W.—Wild Juniper, Juniperus communis.——Col. S.—Isoplexis canariensis (syn. Digitalis canariensis). Greenhouse evergreen shrub, not hardy in this country. ——(G. P., Sheffield.)—Cryptomeria japonica.——(S. B.).—1, Lonicera nitida; 2, Clematis heracleifolia.

TRADE NOTE

A PARTICULARLY attractive and useful hybrid musk rose that will in all probability share the undeserved fate of several of the same class unless attention can be drawn to it now is Vanity. (Raised by Messrs. A. J. and C. Allen.) This variety has large trusses of a delightful shade of rose pink flowers, single in form, about 3½ins. to 4ins. across, all of which open perfectly in all weathers. It is a very vigorous grower and easily attains 6ft. to 7ft., but the value of it lies in the fact that it is continually in bloom, and it is hard to portray the beauty of a specimen bush of this variety in full bloom. It was introduced in 1920 and would now be in demand if only it had been more extensively shown. It is a variety which will delight all rose lovers and will lend itself to most effective results planted for a hedge.

CATALOGUE DESCRIPTIONS

A CORRESPONDENT who is exceedingly interested in tiny plants (having a small garden) and who searches Europe for them has asked the advice of our Service Department with a view to our describing the habits of some primulas that have been sent to him from the Continent. He complains with some heat and a great deal of justice that catalogue descriptions of rare plants are woefully meagre. He says that what would be useful would be a hint of their requirements in the direction of

(A) Light and shade
(B) Compost and whether calcifuge or not (this, of course, refers to primulas)
(C) Moisture
(D) Need for protection in the winter
(E) Nature of root system
(F) Habit and space required
(G) True colour description.

This last point I have already discussed in THE GARDEN. No two people see colour with the same eye, and our colour vocabulary is inadequate and in a terrible muddle.

The other six points, however, strike at the root of the constant complaint of nurserymen that it is little use growing uncommon plants for the general public because they will not buy them. How often do you hear it stated that such and such a plant is not hardy or that it will not grow in a certain part of the country? I hear it almost daily, and yet I know that in nine cases out of ten those statements are not true, that the plant is perfectly hardy and that it will grow and flourish—under certain conditions. And yet one cannot blame the public, for after all, to them, gardening is only a hobby, whereas it is a nurseryman's duty to know how every plant he sells should be cultivated; only he is unwilling to spend more money on printing cultural notes. This is really a false economy, for there are many plants which would be welcomed to our gardens if only a few hints were given about their cultivation.

One catalogue containing an excellent list of plants states that cultural notes are sent out with every plant, but this is not of much assistance to beginners who wonder which of these hundreds of plants are going to flourish in their gardens.

The nurseryman's point of view is that it costs money to print a catalogue, and if he gives full instructions it would be trebled or quadrupled in size. He also says that this is a job for authors of books on gardening or for the horticultural Press. So it is, but there is a psychology about buying from a catalogue which makes prospective customers impatient of having to go to a file of a gardening paper or to wade through various tomes to find a description of a certain plant and find out what it looks like. If a plant is worth its salt a full description would more than repay the cost of printing.

Let me see if I can explain what I mean by an adequate description of a new and fairly uncommon shrub:

> Viburnum fragrans, a Chinese deciduous shrub of good habit and perfect hardiness. The foliage is handsome and it will make a growth of a foot or more in a favourable year, ultimately becoming a bush of 12 or more feet in height and at least 6ft. in diameter. It flowers from January to March and carries numbers of small tubular flowers either shell pink or white, of a delicious fragrance. It will grow in any loam or in lime, but will suffer if allowed to get too dry. It is one of the best of our early-flowering shrubs, as the flowers will stand 10° of frost and it does not require pruning. One of its disadvantages is that it does not flower freely until it is 4ft. high.

This appears to me to be a fair description as I know the plant, and yet how often do you see a plant so catalogued? I am sure that such a description would sell rare plants of real worth. The advantages are given, also the disadvantages, the size, shape and colour of the flowers, soil it will grow in, hardiness, time of flowering, fragrance.

This may appear to be a case of trying to teach a nurseryman his business; but a salesman does not always see eye to eye with a purchaser. I know that in many other trades the more fully an article is described in a catalogue the more are sold and the easier it is to sell them—and, after all, a plant is an article for sale. I should very much like to get the views of some readers of THE GARDEN on catalogue descriptions.

A FINE DECORATIVE SHRUB

FUCHSIAS HAVE LONG BEEN POPULAR IN SMALL GARDENS, ALTHOUGH THEY HAVE BEEN SERIOUSLY NEGLECTED OF LATE YEARS BY THE SPECIALIST.

FUCHSIAS in many beautiful varieties are very popular for conservatory and greenhouse decoration, as well as for summer bedding, for which purpose many of them are well adapted. They also make excellent window plants, being great favourites with cottagers. And in this connection it is interesting to note that the first fuchsia is said to have been brought home by a sailor, and was seen growing in his window by Mr. James Lee, nurseryman, Hammersmith, who secured the plant. In any case, it seems certain that the fuchsia was first cultivated and distributed by Lee of Hammersmith.

In addition to the species and many varieties that are used for indoor decorative work, there are quite a few which are more or less hardy, for even if they get cut to the ground during the winter in the colder parts of the country, they usually spring up from the rootstock again, especially if they are protected with some dry ashes.

The sorts that succeed outdoors are usually varieties of F. macrostemma, although another beautiful species, viz., F. fulgens, usually succeeds if planted at the foot of a warm wall; but it is the varieties of F. macrostemma that one usually finds planted outdoors, the variety Riccartoni being the one most commonly seen, and which forms huge bushes and hedges in the south and west, and all up the west coast of Scotland, even in the colder parts of the country, where it has to be cut down every spring. It makes annual growth some 3ft. in height, and flowers freely throughout the summer and autumn. Fuchsia macrostemma var. gracilis can be used in the same way and, with F. Riccartoni, should be more used for planting permanent lawn beds. At Kew they stand in such beds without protection, and, although the shoots get killed to the ground every winter, they never fail to make annual shoots 3ft. or 4ft. in height, and flower profusely all the season. Other good varieties of F. macrostemma are conica and globosa, while the beautiful variety known as F. macrostemma gracilis var. variegata is very largely used in summer bedding arrangements, its light elegant habit making it very useful for planting over dwarfer plants.

F. corallina syn. F. exoniensis in favoured parts in the west of England makes large specimens and is a beautiful plant for training on a warm wall. F. procumbens, a curious trailing species from New Zealand, is more or less hardy in favoured parts, and is excellent for small hanging baskets in the cool greenhouse. Other more or less hardy species which one occasionally meets with in the south and west are F. microphylla and F. thymifolia, both with small flowers and foliage. The following are species that should be regarded as purely greenhouse plants, viz.: F. triphylla, a very beautiful plant, but, I am afraid, not at all common in cultivation at present; it is by no means an easy doer, and its place is generally taken by a stronger-growing variety known either as Mary or as F. triphylla superba. F. corymbiflora and its variety alba are handsome greenhouse shrubs and are seen at their best when planted out in a bed or border in a cool conservatory, as also is the distinct F. arborescens, syn. F. syringæflora. F. simplicicaulis is another beautiful species which is seen to best advantage when planted out and trained to a rafter. This, with F. splendens, possibly includes all the best species at present in cultivation. Beautiful as the species are, it is the numerous garden varieties, both single and double, that are generally cultivated for greenhouse work and summer bedding, as well as by the market gardener. At one time large old specimen fuchsias were common in gardens, but at present smaller plants that can be more generally used for decorative purposes seem to be in greater favour.

Fuchsias are easily propagated by means of cuttings of soft young shoots. Put in during the spring, they root readily in a close case with slight bottom heat. If it is desired to have large specimens quickly, cuttings should be rooted during September. For this purpose some stock plants should be partially cut back during August and placed in a house with moist growing temperature of 50° to 55° Fahr. Such plants will soon give a good supply of cuttings which will root readily in a close case.

The young plants should be kept growing on steadily all winter; generally, they may be wintered in 48-sized pots. The leading shoots should not be pinched, but kept tied up to a neat stake. Early in the New Year the young plants will require to be potted on, and as they are free-rooting plants good shifts may be safely given. They should be shifted on as they require it until they are in 10in. or 12in. pots, using a compost that has been stacked for at least twelve months, one-third of which may consist of old mushroom-bed manure or leaf-soil, with enough sand to keep the whole open and porous, adding a 6in. potful of fine bone meal to every bushel of soil. As indicated, the leading shoot should not be pinched, but to get well furnished plants the laterals may be stopped at every second leaf up to six weeks before they are required to flower, which may be during July or August. By this means specimens 6ft. to 8ft. in height can easily be produced in twelve months. Such plants can, of course, be kept for next year, or if so desired may be kept for years, storing them in a dry, frost-proof building during the winter, pruning them back and starting them into growth early in the year. Such large specimens are well adapted for making a display in the flower garden during the summer, being most effective when underplanted with dwarfer plants.

Where standard plants are desired they should be grown in the same way as indicated for pyramids, inserting the cuttings during September, keeping the leading shoot tied up to a stake: with the exception that all lateral shoots should be suppressed until the main shoot has attained the desired height—3ft. to 5ft.—when

FUCHSIA MACRORSTEMMA RICCARTONI ONE OF THE MOST HARDY OUT-OF-DOOR VARIETIES.

Digitized by Google

the growing point should be pinched out and the laterals allowed to develop to form the future head of the plant. Where small bushy plants are required for furnishing stages and for general decorative work, cuttings may be put in

FUCHSIAS ARE USEFUL FOR INDOOR DECORATION.

early in the New Year, the young plants being pinched several times to induce a bushy habit. Fuchsias, especially the stronger-growing varieties, are ideal for draping rafters in the conservatory, as they flower in great profusion right throughout the summer and autumn. For this purpose they are best planted out in beds or borders. When the plants have filled their allotted space, they should, early in the year, be pruned hard back. When growing, the shoots should be trained to cover the given space evenly and allowed to grow as naturally as possible. In this way the flowers are displayed to best advantage.

Baskets.—Many varieties of fuchsias are ideal for filling hanging baskets. For this purpose those with a natural drooping or pendent habit are best, such as Mrs. Rundle; Mrs. Roberts; Caledonia, a macrostemma variety; Wave of Life, with golden foliage and slender drooping shoots—this makes a very beautiful basket plant and flowers freely, keeping in good condition longer than any of the other varieties; H. Henckel, with beautiful dark-coloured foliage and long salmon red flowers: this distinct variety is no doubt a fulgens hybrid—it is also very beautiful for summer bedding.

Some of the double varieties are naturally of a slender drooping habit, and are thus excellent for furnishing baskets. Ballet Girl and Molesworth, two old varieties, are well suited for this purpose. There are, of course, many varieties, and for general cultivation one might mention Sylvia, Phenomenal, also Rose and White Phenomenal, the new Pink Pearl, and Dainty Lady, the first fuchsia for many years to receive an award of merit. There are also numerous single varieties, a few standard sorts being Mrs. Marshall, Amy Lye, Charming, Flocon de Neige, Rose of Castile Improved, Lord Grenfell, Lustre, Display, Princess Mary and Royal Purple. There is also the distinct hybrid set of Continental origin, which includes Thalia, Coralie, H. Henckel and G. Bonstedt, all of which are useful either for greenhouse decoration or summer bedding. Fuchsias are easily raised from seed, and there is always the chance of obtaining improved varieties. Fuchsias usually set seed freely, but the seed vessels must be kept picked off, as seed production is an undue strain on the plants and they quickly go out of flower if allowed to produce seed. When in flower and their pots well filled with roots, they require ample feeding; if this is neglected their flowering period will be greatly curtailed. Fortunately, fuchsias do not suffer greatly from insect pests, although during recent years white fly has proved troublesome; this must be prevented or kept in check by fumigating with hydrocyanic acid gas or some of the other approved remedies that are now on the market. Mealy bug also proves troublesome, especially on old specimens. This pest must be kept in check by syringing and sponging regularly with some approved insecticide. J. COUTTS.

FRIENDS AND FOES OF THE GARDEN—I

BY CLIFFORD W. GREATOREX.

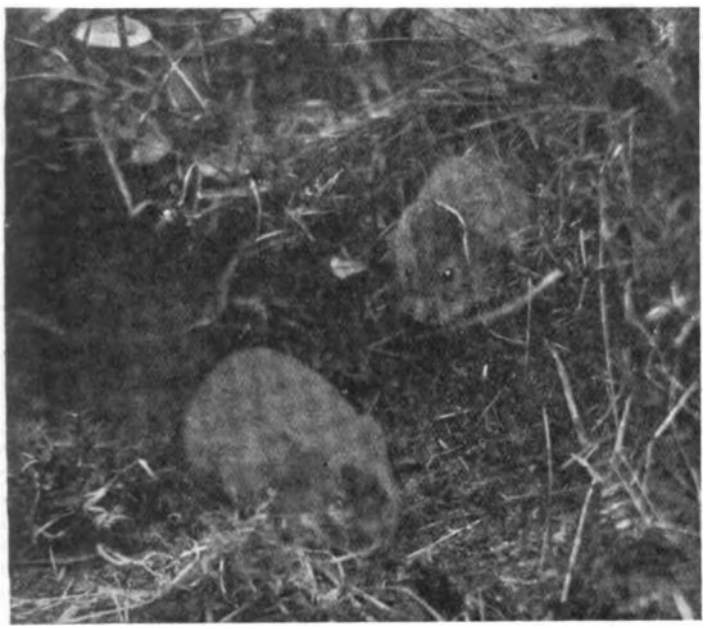
AMONG the furred and feathered inhabitants of the garden are both friends and foes. The owner of even the smallest plot does well to learn how to distinguish between the two. Should he confuse them, serious mistakes may be made, and the creatures that are beneficial may suffer the fate of those that are harmful.

To begin with, there is the mole. "The little gentleman in velvet" renders a certain amount of good service by draining and ventilating the soil and by clearing it of grubs—especially of leather-jackets, wireworms and the larvæ of cockchafers. But molehills are nothing but disfigurements. Even that devoted naturalist, the late W. H. Hudson, was obliged to admit that when moles visit lawns and gardens they are a nuisance. He adds, "if someone could devise a means to inflict sudden death on every underground intruder into such places it would be a great advantage." So intense is the activity of the mole that a single individual can spoil the appearance of a garden or a lawn—or of both!—in a remarkably short period of time. Moles, of course, feed largely on earthworms; but the value of earthworms as fertilisers of the soil is well known, and we need not be grateful to the moles because they destroy vast numbers of these useful creatures.

Then there are the various species of mice and voles. Voles may be known from mice by their stouter build, their relatively smaller ears, usually hidden among the fur, and their small eyes. Both mice and voles are extremely harmful in the garden, and the same remark applies, of course, to the ubiquitous brown rat. Even the water vole, which helps to

A MOLE-HILL IN SECTION SHOWING THE NEST

Digitized by Google



ENGLISH MEADOW VOLES.

prevent the choking of canals by feeding on aquatic and sub-aquatic plants, becomes a nuisance when it enters the garden. For here it injures the potatoes and the vegetable marrows.

The long-tailed field mouse is an attractive looking little creature, with its elegant form, its bright, full eyes, and its remarkable elongated tail; but it works very serious havoc when it gains access to the garden. The slight amount of good it does by devouring certain insects is heavily outweighed by the damage inflicted upon newly sown crops of various kinds. Peas and beans are taken by the pint and stored away in the burrows of this animal.

The short-tailed field mouse or common vole, and the red-backed meadow mouse the name of which is an adequate guide to its identification, are the worst of all the furred enemies of the garden. Like the long-tailed field mouse, these voles carry away great quantities of beans and peas to their burrows; but, in addition to this, their diet comprises practically every sort of vegetable, and they are exceedingly voracious.

Vole-plagues occur from time to time. Were the numbers of these animals kept in check year by year, such disastrous superabundance might not come about. When such a plague occurred in Dean Forest and in the New Forest, many years ago, the most effectual mode of dealing with the devastating swarms was found to be as follows: "A great number of holes were dug in the ground, about two feet long, eighteen inches wide, and eighteen inches deep. This is the measurement at the bottom of the hole; but at the top the hole was only eighteen inches long and nine wide, so that when mice fell into it, they were unable to escape. In these holes upwards of forty thousand mice were taken in less than three months, irrespective of those that were removed from the holes by stoats, weasels, crows, magpies, owls and other creatures."

The dainty little dormouse, which is a fairly frequent visitor to country gardens, may be recognised at once by its squirrel-like form and habits. It may often be seen, sitting up on its haunches and grasping its food with its fore paws, in a manner strongly suggestive of "Shadow-Tail" of the woods. The head of the dormouse is rather large, its eyes are black and very prominent, and its tail somewhat stout and bushy. The gardener need not object to the presence of this charming little creature within his territory, for the dormouse inflicts no injury upon any of his valued plants, feeding on acorns and fruits of hedgerow trees and being very partial to aphides, weevils and various caterpillars. Hence, it is worthy of encouragement rather than of repression.

Should the stoat or the weasel pay a visit to the garden, the owner thereof has reason to be glad; for no rat, mouse or vole, can ever look upon either of these bloodthirsty and agile little beasts and live! Of course, if a corner of the garden be occupied by chickens or pigeons, due precautions must be taken!

In woodlands and on low ground they certainly make a great deal of havoc and are especially harmful to game. The stoat is of more importance in this respect than the weasel, from which it may be readily distinguished by its greater size, and by a blackish tuft on its tail which is retained throughout the winter, when the rest of the body becomes almost white. These creatures, therefore, should not be allowed to multiply enormously in game coverts, but on the other hand, weasels should not be unduly molested as they do considerably more good than harm to the gardens.

Either stoat or weasel will put to rout that troublesome rodent, the rabbit, which is all too fond of paying its attentions to the lettuces and cabbages when evening shadows lengthen, or when morning twilight broadens into day. The hare, too, will not continue to take toll of the garden produce should stoat or weasel appear upon the scene.

A staunch ally of the gardener is the hedgehog. "Prickles" is never happier than when he is feasting on caterpillars, snails, centipedes, earwigs, beetles and similar creatures. He has no liking whatever for vegetable substances; although, previously, there prevailed a general belief that he dug up roots and ate them. His taste is carnal. In the course of his nocturnal wanderings he will seize other animals—mice, rats and voles—and his sharp teeth and claws make short work of them.

Then there are the shrews, wrongly named shrewmice. Though decidedly mouse-like in general build, these little animals may be recognised immediately by their remarkably elongated muzzles. Unlike the mice, the shrews are really valuable to the gardener. They achieve what most insecticides often fail to effect. Their teeth are formed for dealing with insects both large and small. A vegetable diet does not appeal to them at all. The man who allows his cats to amuse themselves by killing the shrews in his garden is acting contrary to his own interests. It would be wiser were he to abolish the cats!

The multitudinous insect hosts, a large proportion of which consists of species injurious to garden plants, are assailed not only from the ground but also from the air. With the coming of night appear the bats: one and all exclusively insectivorous. These nimble creatures continue by night the priceless services that the swallows and martins and swifts perform during the day. The noctule, or great bat, feasts on cockchafers and large moths. The smaller kinds of bats account for vast swarms of lesser insects. Those moths whose caterpillars disfigure leaves by rolling up their edges are disposed of in great numbers by the pipistrellæ and the long-eared bats. Myriad two-winged flies, many of which are pests, are destroyed by these gnome-like creatures that haunt the darkness and the dusk.

A DORMOUSE WITH ITS NEST OF LEAVES. IT IS TO THE GARDENER'S ADVANTAGE TO ENCOURAGE THIS CREATURE.

THE MORAINE OR SCREE GARDEN

BY CLARENCE ELLIOTT.

IN the beginning, Farrer invented the moraine garden, both the thing itself and the name. He wrote it up and popularised it, and a very valuable invention it was. Others, too, since those early days, have experimented with and elaborated the moraine garden, and their elaborations have chiefly been in the direction of underground watering to reproduce that underground water-flow which occurs naturally in real moraines in the Alps.

The real moraine in its wild state is perhaps the ugliest and most desolate thing in nature—a tract of crushed and broken stone, carried down and pushed out by the slow, irresistible flow of the glacier above, and watered all summer by a constant percolation of glacier water. The material of the moraine consists of stone crushed to the fineness of powder, rocks as coarse as cottages, and rock of every grade intermediate between these two. Although a moraine from a little distance looks about as dreary as the City on a Sunday, it turns out on close inspection to be a glorious home of some of the most beautiful alpine plants. Most of them are frail-rooted things whose habit it is to ramble through the loose shingly ground. In the garden, too, loose shingly soil they must and will have—or perish. Put them in the ordinary full, fat pudding soil of the general rock garden, and they will be stodged out of existence in no time. And so came the moraine garden, a portion of the rock garden, in which, in place of normal loamy soil, one provides a shingly mixture of stone chips and sand.

But besides moraines there are also screes in the Alps. In composition they are practically the same as moraines, though they are formed in a different way. A scree is usually a slope of stone, broken and fallen from a cliff by a process of gradual disintegration, and piled against the base of the cliff from which it was formed. Not being glacier-formed the scree usually lacks the all-summer water flow of melting glacier. Yet screes are just as rich in flowers, often richer, than moraines. In general character scree plants and moraine plants are much alike, and a great many species are common to both formations.

Now, my own experiments with moraine gardening have all been in the direction of simplification rather than elaboration. Elaborators have been out to invent synthetic glaciers to provide the underground waterflow. Taps, valves, pipes, concrete bottoms, overflows, traps and sinkaways have made it a hobby rather for sanitary engineers than for flower lovers. In my own moraine gardens I have entirely left out all such contraptions. I have adapted from the scree rather than from the moraine—in fact, they are scree gardens, and I have now adopted that name and dropped the term "moraine garden," except when reference is made to the other school.

Very good results have certainly been obtained in underground-watered moraines, but my own experience is that equally good results are to be achieved by depending on rain and occasionally the hose or the watering-can.

How, then, to make a scree garden? Let us suppose that you have an existing well-built rock garden. Why not adapt one portion of this, and convert it into a scree? It is the simplest way. Go over the rock garden carefully, and select one definite portion, an open sunny slope, bounded and contained by well sunken rocks. Remove any plants that may already be growing in it, and then take out all the existing soil within its boundaries to a depth of at least 18ins. If it is not very definitely bounded and enclosed by rocks, it will be well to introduce enough rocks to complete an irregular half-sunken boundary, to act as a barrier to keep out plants which might invade your scree from the surrounding soil. Next arrange your drainage. For this all you need do is to cover the floor of your excavation with rough broken stone, brickbats, anything of this nature, to a depth of about 6ins. Lastly, make up a sufficient heap of scree mixture to fill the rest of your excavation. Take broken stone, silver sand and leaf-mould or good loam (the former is best) in the proportion, roughly, of four or five parts stone to one of soil and sand. The proportions are only approximate. It is best to err on the side of too much stone than too much soil. A slight top-dressing of soil can always be added later, and will soon get watered in and worked down among the stone. Do not be nervous about this mixing of the scree mixture. There is no need to approach the matter as though you were making up a prescription with dangerous drugs. Go easy with the soil, as though it were garlic in a salad, and you will not be far wrong; and as to what stone chips to use—use what you can get. A few of the nurserymen who specialise in alpine plants sell both ready mixed scree mixture and ready crushed limestone chips, to which the other ingredients may be added.

If you have stone in your neighbourhood easily available, it is a simple matter to break up with a hammer enough for your requirements—unless they are very ambitious. Then, having got your drainage in position and your scree mixture mixed, all you have to do is to fill up the rest of the cavity with it, and your scree is ready for planting. In other words, a scree garden is nothing but a portion of the rock garden large or small, and small for choice for a start, at any rate, in which a very stony, shingly compost is substituted for ordinary soil.

The kind of rock does not very much matter. Limestone, sandstone, millstone grit, Kentish Rag, or even granite will do. And in size the chips and bits and pieces may vary from the size of filberts to the size of apples, and the crumbs and the dust should go in as well. And then will come the fun of planting. But the odd thing is that most folk set out with the idea that they must have a scree or moraine, and then begin to wonder what they shall grow on it, ending up by growing all sorts of quite ordinary plants which they could grow equally well in any other part of the rock—or kitchen—garden. I have read accounts of wonderful successes with Saxifraga Aizoon in the moraine. And Campanula Miss Willmott!

PLANTS IN THE MORAINE FLOURISHING IN A COMPOST LARGELY CONSISTING OF STONE.

Digitized by Google

The scree garden (and the moraine) were evolved for the cultivation of certain plants, some of which grow naturally on screes and moraines in nature, and which succeed better in scree gardens and moraine gardens than in ordinary rock garden and full loam conditions. Here, then, follows a list of a few plants which will thank you for a scree. Lime haters are marked with a star. The others either like lime, or are indifferent: Androsace arachnoidea, *A. glacialis, *Anemone baldensis, Asperula suberosa, Campanula Allionii, C. arvatica, C. kewensis Phyllis Elliott, C. Waldsteiniana, C. Joysii, Dianthus Musalæ, D. neglectus, D. Freynii, Douglasia vitaliana, Draba pyrenaica, Gentiana verna, G. brachyphylla, G. imbricata, *Geum reptans, Linaria alpina, Myosotis rupicola, Omphalodes Luciliæ (limestone scree in shade), Papaver alpinum, Potentilla nitida, Ranunculus Seguieri, Raoulia australis, Saxifraga Burseriana and almost any of the Kabschia species, S. oppositifolia in all its forms, S. retusa, Thlaspi rotundifolium, Viola valderia, V. heterophylla, *V. cenisia, *Campanula cenisia, Dianthus alpinus, *Chrysanthemum alpinum, Wahlenbergia pumilio and W. serpyllifolia. The above is a very select list of plants which really appreciate scree conditions, though some of these even may be grown without full scree.

DECIDUOUS SHRUBS

BY SIR HERBERT MAXWELL.

AMONG the many rare plants exhibited at the Truro Flower Show last May, none attracted more admiration than Staphylea holocarpa, introduced from China by Mr. E. H. Wilson in 1908. It appears that it was stocked by certain nurserymen, but failed to attract purchasers, and now diligent search has failed to find any who can supply it. However, it exists in a few private collections, where it puts forth a mist of delicate pick blossom in spring—a truly lovely plant.

The common privet, Ligustrum vulgare, is so common as to deter some people from taking an interest in the genus. Nevertheless, it contains some very attractive shrubs, among which the deciduous L. sinense is perhaps the best. It grows 20ft. high and flowers rather late in summer. There is a plate showing a fine specimen in Mr. Bean's "Trees and Shrubs," Vol. II, page 28.

One seldom sees Exochorda grandiflora in private collections, but it is well worth a place in the most exclusive. Like the Chinese privet last named, it was introduced from China more than seventy years ago, and would assuredly be more sought after were it better known, for it is an exceedingly beautiful object in May when decked with racemes of large, pure white flowers. It may grow ten or twelve feet high and bears plenty of seed.

THE PEARL BUSH, EXOCHORDA GRANDIFLORA, WHICH IS WORTH A PLACE IN A COLLECTION.

There is a multitude of good shrubs in the genus spiræa, but if I were limited to three species they would be S. arguta for spring flowering, S. bracteata for early summer and S. Veitchii for July. Mr. Wilson has pronounced the last-named species to be the finest of the Chinese spiræas; but I would plead hard to be allowed a fourth species—the noble S. arborea, which tosses its great plumes of ivory-white blossom at any height up to 20ft. S. arguta is content with moderate elbow-room, but the others demand liberal space if they are to be seen at their best.

The noblest hydrangea is H. vestita; it has been in this country for more than a century; yet, except in botanical gardens, I have never seen it except in my own grounds, where it stands 20ft. high. The flowers are white; but those of H. villosa, introduced by Mr. Forrest, display many delicate tints of violet, rose and pale blue. It is desirable both for these and for its softly hairy foliage; but I am not aware that it has found its way into commerce.

Deutzia longifolia, one of Mr. Wilson's choicest introductions from China, is among the handsomest of its family, especially the variety named Veitchii. The flowers are produced in panicles, varying in colour from deep rose to white.

Among the witch hazels there is none that can compare with Hamamelis mollis, which begins in midwinter to wreath its bare branches with fragrant golden flowers that stand untarnished even through severe frost.

There are so many districts in which the lovely Abutilon vitifolium will flourish in the open (I have seen it covered with lavender bloom far inland in Sussex), and so many others in which it only requires to be planted against a wall, that it is surprising that it is so seldom seen except in maritime places. It is true that it is not long-lived, but often survives up to the age of fifteen or thereabouts. It ripens plenty of seed, from which a fresh stock may easily be raised. It is well to observe some care in taking the seeds out of the capsules, for they lie embedded in a mass of hairy packing, which the lightest draught of air raises in a cloud, most irritating if inhaled.

Xanthoceras sorbifolia is a Chinese relation of the horse-chestnut, and resembles it in the large capsules that contain the seed. But in other respects it is very different from its stately cousin, growing only 20ft. high, with long, pinnate leaves which give the little tree a pretty, feathery outline. The flowers are produced in May in long erect panicles, with white petals blotched at the base with reddish chocolate. It does not flower freely except where it gets plenty of sun; but it is a beautiful thing at its best.

On the other hand, Lonicera tragophylla becomes covered with aphis if exposed to strong sunshine. It is splendid when trained on a north wall, for its rich yellow flowers, though scentless, are the largest of any climbing honeysuckle and are very freely produced.

The list of desirable, out-of-the-common shrubs might run to inconvenient length; wherefore, writing as I do in October, I will bring it to a close with Cercidiphyllum japonicum, which, although the largest deciduous forest tree in Japan, is more likely to behave as a shrub in this country. The flowers are inconspicuous, but the glory of the plant consists in the wonderful colour of the foliage in autumn, varying from bright yellow and carmine to deep purple maroon. It is of special value for house or table decoration, inasmuch as the cut sprays retain the leaves a long time, whereas those of the equally brilliant Parrotia persica drop off almost immediately.

A BORDER OF SOUTH AFRICAN BULBS

IT IS PLEASANT TO SEE THAT SOUTH AFRICAN PLANTS ARE AGAIN BECOMING POPULAR. ALTHOUGH THEY ARE USUALLY SEMI-HARDY, THEY FLOURISH IN SHELTERED PLACES.

THIS, surely, would prove the solution of many of the small difficulties that beset the cultivation of the various beautiful bulbs and bulbous-rooted plants which come to us from South Africa. Think, for example, of the Ixia (African corn lily), the wonderful Gladiolus primulinus (maid of the mist), the babiana (baboon root) and a host of others, and imagine these *permanently* established out of doors in a special border made up and planned to meet their requirements. Most of these are just on the borderline of perfect hardiness, and yet one is never quite safe, so that annual lifting, drying and replanting has to be done. Over a large part of the country, however, all this *could* be avoided, but only by the method of allotting them a special position and making up a special border.

The position we may dismiss in a few sentences. Firstly, it should be warm and well protected, and must be in the very sunniest position that your garden can supply. This probably means facing due south and at the foot of a brick wall, for one gains much by the absorption and radiation of heat from this. Only one improvement could possibly be suggested, and that is on the south side of a heated greenhouse, for here the soil practically never freezes and so conditions are almost ideal.

GALTONIA CANDICANS, THE IMPOSING CAPE HYACINTH IN ASSOCIATION WITH GRACEFUL SPIKES OF GLADIOLI.

Having selected the site, the next point is to prepare the border. This, once again, must be raised above the level of the surrounding ground, so as to provide very free drainage. It is easy to provide sufficient water in dry times, but impossible to keep the soil dry enough in winter without raising the bed and draining the ground. The border need not be a very wide one. The natural earth should be removed to a depth of 2ft., and at the bottom 9ins. of clinker, brick ends, etc., should be placed. Over this should come 15ins. of fibrous yellow loam that has been mixed with one-third of its bulk of coarse sharp silver sand. Turn this again and again, so as to make sure that the soil and sand are thoroughly mixed together, and plan your border so that it is 6ins. or 9ins. above the level of the surrounding ground.

In most cases this—with the shelter of the wall—will prove sufficient; but, if the garden is a cold one, a winter covering of 6ins. of strawy litter may be used in addition. This, however, should not be regarded as a permanent covering, but rather used in very frosty times and removed when the weather is milder. This remark applies especially to that half of the winter which comes after Christmas, for if the covering is retained all the time it is certain to encourage premature growth that, when the covering must be removed in spring, is liable to suffer by exposure to cold winds. The bulbs should be planted at different times in the year: some in autumn, others not until the spring, but in every case a small pile of sand should surround them, so as finally to settle the question of efficient drainage.

Having disposed of the question of position and having described the making of the border for the reception of the various bulbs, corms and tubers, let us glance at some of our material. South Africa is especially rich in these beautiful flowers, and the choice is no mean one, but their range could, of course, be infinitely extended by wanderings to other parts of the earth, for we might include the glorious Peruvian lilies (that are not lilies at all, but only look like them), the fine tiger flower of Mexico, etc. All of these would flourish under identical conditions, and all would appreciate the free supplies of water in summer that are so essential to support the vigorous growth that is usually being made at that time. Let us, however, confine our searches to-day mainly to South Africa.

For convenience, too, it will be well to separate our bulbs into two classes—those that are planted in autumn and those that are put in during spring. At the head of the autumn list come the Ixias, delightfully graceful plants with exquisite loose racemes of flowers, remarkable for their diverse and brilliant colouring. Culture in our outdoor border begins in November, although the planting of the bulbs may be deferred until early in the New Year so as to make sure that they do not appear above the surface too soon. The bulbs for permanent planting should be put in 4ins. to 6ins. deep and 3ins. or 4ins. apart, as they increase fairly rapidly and soon become overcrowded. There are many named kinds of striking beauty, enhanced in every case by the dark "eye," but a mixture, if obtained from a suitable source, will give an immense variety of colours. One would do well, however, to invest in a dozen or so of the unique green variety, in which the flowers are an intense sea green enhanced by a dense black centre. Do not mix these with your other Ixias, but give them a special place by themselves, so as to make them one of the features of the border in May and June. Do not overlook the point of keeping these uncovered by straw whenever possible, for no bulb is more liable to early starting and, if one is careless in this respect, it is not uncommon to discover that a couple of inches of top growth have been made far too early in the year.

Babianas and sparaxis both respond to identical culture, but are not nearly such popular flowers, despite their wonderful colourings and veinings and extreme brilliance. All species of sparaxis are South African, and the majority are about 1ft. in height. The flowers are tubular and strikingly blotched at the base of the petals. Colours range from deep violet through yellow and white to orange red, and flowering takes place in May and June. A very different form is Sparaxis pulcherrima, which flowers in September and October and attains a stature of from 3ft. to 6ft. This has sword-like foliage and slender flower-stems which bear many funnel-like drooping flowers deep blood red in colour. This is not always listed under sparaxis, but may be found under Dierama pulcherrima.

The babianas, again, are all South African and rarely exceed 1ft. in height, while the colours are startlingly brilliant.

Digitized by Google

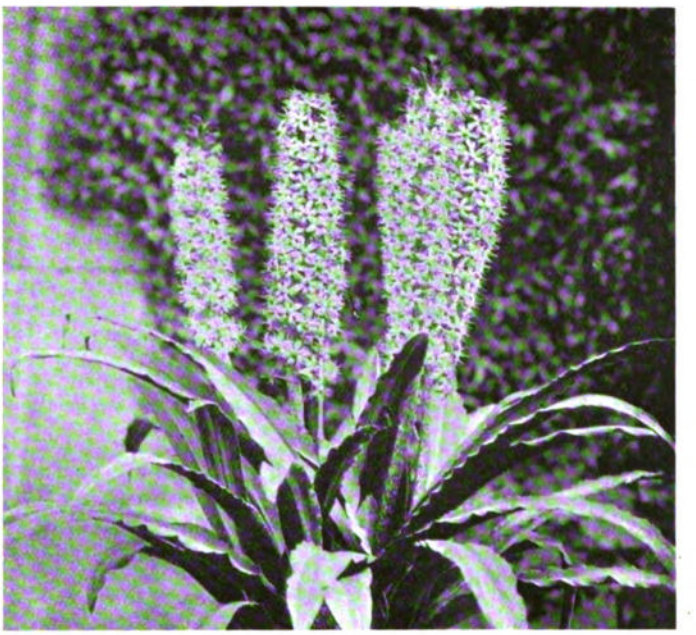
The variety stricta presents the unusual picture of having the three outer petals white, while the three inner ones are violet-blue. Two other varieties may be singled out for special mention: disticha, violet-blue, with the fragrance of the hyacinth; and plicata, violet and smelling like the clove carnation.

Coming to spring planting, Schizostylis coccinea is especially valuable for its late flowering—November—with its vivid scarlet gladiolus-like flowers, each of which is 2ins. across. The foliage is sword-like, the lower leaves being the longest and the upper ones forming bracts. This increases rapidly and the leek-like tufts can be pulled apart and replanted. Owing to its late flowering it is best to give slight protection when the buds form, and especially to shade the spikes in the early morning after a frosty night.

A charming effect can be created at the edge of our border by using Anomatheca cruenta, the foliage of which resembles montbretia, while the flower resembles the freesia—that is, in all save height and colour. The growth does not exceed 6ins., and the small crimson scarlet flowers continue to expand throughout July and August. One need have no doubts as to its hardiness, although it certainly prefers a very sunny position. Seed ripens freely and sows itself, the young flowering plants reaching maturity within a year or two. A lovely new form with glistening white flowers should also be noted; but, as this is rather expensive, while the old cruenta is very cheap, the white form should be used for forming small clumps, while the brilliant crimson scarlet variety is reserved for edgings.

Those who are responsible for house decoration will welcome Gladiolus primulinus in no half-hearted manner. The hooded yellow flowers are exquisite, and the habit so slender and graceful that it leaves nothing to be desired, either from the garden point of view or when arranged in water. The new race of primulinus hybrids are no less

WITH ITS VIVID SCARLET FLOWERS SCHIZOSTYLIS COCCINEA IS ESPECIALLY VALUABLE FOR LATE FLOWERING.



FOR BEAUTY AND FRAGRANCE EUCOMIS PUNCTATA IS USEFUL IN THE BORDER.

beautiful than the type, and the mixing of their blood with varied garden hybrids has resulted in a series of shades of cream, flesh, salmon, etc. Tritonia crocata, Prince of Orange, is perfectly hardy and very valuable for summer flowering in masses, for its sprays of orange scarlet flowers not only give a fine effect in the borders, but are extremely decorative for cutting purposes. Less hardy than the above, but quite amenable to culture in our special border, is Tritonia rosea, which reaches a height of 1½ft. and bears most lovely rose-hued flowers of similar form. In planting these it is better to keep the two varieties separated some distance from each other, because the vivid orange is apt to kill the rose pink and *vice versa*.

Contributing beauty, fragrance and a very striking and unusual appearance, Eucomis punctata is not a bulb to miss. The broad strap-like green foliage is decorative all through the summer and has the advantage of not losing its freshness before the flowers expand. In our outdoor border it flowers in August and September, and advertises the fact far and wide by its powerful but pleasant perfume. The starry flowers are closely arranged on a long spike, greenish in colour and purple brown in the centre. At the top of the flower-spike is a series of conspicuous purple-edged leafy bracts, while the whole of the thick stem that carries the flower-spike is heavily spotted with purple brown. The large bulbs should be planted not less than 6ins. deep, and ripening is greatly assisted by covering with a frame light in winter.

Watsonias, of which the best known variety is Ardernei, are valuable for their height (2½ft.) and the massive flower-spikes which, if promptly cut out, are soon followed by secondary ones that thus give a very lengthy display. It is wisest to be content with Ardernei for the open ground and leave the coloured species for pots in the cool greenhouse, although humilis, deep rose and flowering in July and August, might be tried in a mild and favoured place. Albuca Nelsoni is yet another bulbous plant from Natal that is not difficult to grow, although it benefits by the addition of a little peat to the soil already recommended. The leaves are of large size, 4ft. to 5ft. in length.

The imposing Cape hyacinth, Galtonia candicans, will thrive splendidly in any soil that is not too heavy, and it is well to introduce it as it lends height and dignity to the border. Towering upwards to a height of 6ft., the stout stems carry a spike of from twenty to fifty large bell-shaped flowers of pure white. One need have no fears on the score of hardiness with this, especially when spring planted and put in at a depth of 6ins. to 9ins., for it reappears year after year with absolute certainty. Planting may be carried out in November, but in this case the bulbs should be covered during the first year by a thick covering of straw or bracken.

H. W. CANNING-WRIGHT.

SHOWS AND SCHEDULES

BY EDWIN BECKETT.

IN the majority of cases this year there undoubtedly has been a considerable increase in the number of entries at provincial and local shows, and probably there have been many anxious competitors studying schedules, endeavouring to make out just exactly what the regulations mean, and these points have no doubt been reflected from time to time in the minds of the judges, when adjudicating on the various classes. Probably the perfect schedule has yet to arrive, and season by season those responsible for their compilation must go through some anxious hours in their attempt to settle the many points that crop up in their endeavour to make their various shows attractive to the exhibitor.

Perhaps a few notes may be of assistance to them, and especially to those who, having just started a horticultural society may be making up their schedules. For the first item let us take the actual phrasing of regulations, in our, at times, rather difficult English language. The primary endeavour should be to write down the rules in the very plainest language possible so that they may be "Understanded of the people." Not an altogether easy task, but one that should be managed with a little careful thought. To illustrate what is meant by this, it is well to quote a regulation that appeared in the schedule of a small society this year, which read:

In the event of there being only one entry in any class, it shall be in the discretion of the judges to decide whether that entry is worthy of any prize, and in the event of there being insufficient entries, in any class for two prizes to be given, it shall be left to the judges in their discretion to say whether in their opinion the exhibits are of sufficient merit to warrant two prizes being given.

That phrasing started well, but what a falling from grace when the term "insufficient entries" was reached, for the society did not define the limit of numbers to accomplish a sufficiency! Result, judges left guessing and calling for the secretary to explain the point, and the secretary unhappy because he also did not quite know the position to adopt. Contrast that wording with the following explicit statement, extracted from another society's schedule:

First, second and third prizes will be awarded where the entries are six and over. Two prizes will be allowed if four exhibits. One prize if only two or three exhibits—first, second or third, at discretion of judges, who shall have power to withhold any prize where the exhibits are considered of insufficient merit.

This was plain and concise, so that the judges knew exactly how to act without reference to the harassed secretary.

This brings us to another thought, which is the lax using of such words as "genus," "species," "kind," "variety," "sort," etc., the mixing up of these often leading to confusion in the minds of exhibitors. The best basis on which to work is to employ only the two terms, namely, "kind" and "variety," so that the first covers kinds of fruit, pears, plums, apples, etc., and the term "variety" varieties of apples, Cox's Orange Pippin, Lane's Prince Albert, Benoni, etc. By doing this, confusion is avoided generally, though it is sometimes desirable further to define the term "kind," for on one occasion this season an exhibitor was observed to employ both French beans and scarlet runners in a collection of nine kinds, curiously enough to form "one kind," an idea that while hardly incorrect, was yet a possible action that might have led the exhibitor on to entirely wrong lines, inasmuch as he might have considered, what after all are only two "varieties" of beans from the exhibition point of view, as two "kinds." Confusion could easily happen in this direction with the cabbage tribe, where such items as cauliflowers, broccoli, cabbage, red cabbage, Brussels sprouts and kales, must each be considered as distinct kinds, and as such should be limited or defined in a schedule.

Another point that schedule makers will have seriously to consider is the definition of terms, where various classes of growers are catered for, such as cottagers, gardeners, undergardeners, amateurs, etc., and the definition of these at times is difficult. I heard of an instance where an exhibitor, who last season ranked as a cottager, this year was placed in the amateur section because, having changed his abode, it was discovered that he paid 2s. a week more rent than previously! A curious happening, but instructive as to the rough and ready methods employed to define a class of grower. Probably in this matter local custom will prove the basis of determination, though it would be far better to base the classification on the very carefully considered suggestions of the Royal Horticultural Society in their most useful handbook "Rules for Judging," and thus standardise the whole business. This handbook should be in the possession of every local horticultural society in the country, for it is a work of sterling merit, and would prove a great help to the schedule makers.

One other point that should always be borne in mind for schedules, especially with regard to local affairs, is not to make too many classes. Consider the abilities of the local growers and put up the classes for them that are likely to receive proper support. It is a pity to make say sixty classes if only about thirty are likely to receive support, for it certainly detracts from the appearance of a show to see half the classes with only one or a couple of competitors exhibiting in them. Better by far to have really keen competition among a large number, for the competition is everything in the endeavour of the societies to encourage and benefit local growing.

Naming of the exhibits should also be aimed at, and it would perhaps be of benefit to all were societies to make this a condition of entry, rather than for them to express the pious opinion that correct naming will be taken into consideration if necessary in keen contests. After all, there are but few growers who raise items of which they do not know the name, and it certainly gives others guidance as to what vegetables, etc., are likely to prove "good doers" in their particular neighbourhood.

The foregoing will give some idea of the main points that will require tussling with; there are, of course, others of minor importance that will crop up, but careful thought will generally clear these away, and it only remains therefore again to urge the importance of clear language and definition.

(To be continued.)

A CURIOUS AND EASILY GROWN CUCURBIT

ALTHOUGH usually called on the Continent the "Siamese" or "Malabar" gourd, and very common in the countries thus mentioned, the subject of these notes, Cucurbita ficifolia, sometimes also known under the name of C. melanosperma, is in reality a native of Mexico, where the first Europeans who went there found it growing wild and utilised by the natives. It is one of the most striking gourds.

There are two points which merit our attention: first, the fine appearance of the fruits, which renders them exceedingly useful for decorative purposes; and, secondly, the possible culinary uses.

For no apparent reason the plant has always been a rare one in gardens. It was introduced to Europe a century or so ago and it is only at intervals that one hears of it in gardening literature. In 1854, for instance, attention was again focussed on it on the occasion of a shipment of a herd of Chinese jacks from Peking to the Paris Museum. The animals were fed on the ship during the voyage with these gourds, and a few which remained untouched on arrival aroused the greatest curiosity. The "Siamese" gourd is a perennial in warm countries, but an annual in northern climates and is a remarkably strong grower. On some occasions, in very hot weather, it has been observed to grow at the rate of as much as 8ins. to 10ins. a day, which means, of course, that by the end of the season it will have reached a fair height. The foliage is faintly splashed dull white in the early stages. The fruits are numerous, oblong and reach an average of 1ft. in length by 9ins. in width and 6lb. to 8lb. in weight. They

Digitized by Google

are, as the illustration shows, very ornamental, the skins being beautifully spotted with white. After ripening, this skin becomes of a very tough consistency, almost woody, and acts as a protection to the internal tissues, which can thus keep for a very long period. In numerous instances, it has been reported that fruits have kept for two, three or even four or five years without alteration. The writer himself knows of a few harvested in 1921 which are still in perfect condition. The only change that takes place is a loss of weight corresponding to an unavoidable loss of water, one-twelfth or one-fifteenth of the total weight, roughly, every year. Needless to say the fruits keep best under very dry conditions. In a humid atmosphere they soon decay. The inside is practically solid, of a somewhat spongy nature and, unlike all other gourds, of a most beautiful white. The black seeds are scattered unevenly in the pulp, which, when properly treated, can very well be used for culinary purposes. In Spain, and in former Spanish colonies, a jam is made with it called "Cabellos de Angel" (Angels' Hair), this name being due to the fact that the cooking does not get rid completely of some of the hard filaments, which when it is eaten produce a most peculiar sensation in the mouth. Another method of cooking the "Siamese" gourd is to make with it a kind of "saurkraut." This dish is very popular in Central Europe. The gourd can also be used for soups, fritters, and so on.

But, leaving the culinary possibilities aside, the decorative value alone of the "Siamese" gourd makes it well worth cultivating. The fruits, with their beautiful white spotting, are excellent for adorning windows, sitting-rooms, and all kinds of odd corners in the house; either alone, or in association with other ornamental gourds, miniature and otherwise, showy fruits, cones of conifers, etc., a method of decoration much in vogue in several countries nowadays. The keeping qualities of these fruits also make them items of peculiar interest. From that point of view, the "Siamese" gourd is certainly very striking.

The cultivation of the plant is very easy and can be compared to that of most cucurbits. The seeds, which one can probably easily obtain in England, or if not, on the Continent (at Messrs. Vilmorin's, in Paris, for instance), are sown at the end of April or the beginning of May, in a house or in a frame, with mild bottom heat, singly or two at a time in small pots. When frost is no longer to be feared they should be planted in the open in their permanent quarters in very rich ground, 6ft. to 8ft. apart. An old hot-bed is an ideal place to establish them and there they generally produce enormous crops. Typical of the majority was one case of a return of 250lb. in the form of thirty-five fruits from three plants, obtained in 1923.

It is also possible to use the "Siamese" gourd plant for decorating exposed banks of large size, where the sun is particularly hot, or to climb up large trellises, pergolas, walls, etc. In the last case it is necessary to assist the climbing stems, as the plant has no natural means of attaching itself to its supports. C. L., *Paris.*

CUCURBITA FICIFOLIA THE "SIAMESE" OR "MALABAR" GOURD.

SOME WILD FRUIT DISHES

IN the lowlands blackberries, on the moors bilberries or wortleberries, are almost the only wild fruits that are in common use for preserves or as a mealtime sweet; the bilberries stewed, and the blackberries in combination with apple, either stewed or in puddings or tarts, or, of course, as jams or jelly. One very rarely hears of any use being made of the other common wild fruits which adorn our hedges at this time of year, for elderberry wine and sloe gin can hardly be called dishes. But I hope to show that there are possibilities in these and variations on the apple and blackberry theme which are worth trying. Moreover, the dishes I shall mention will only be such as I have tried and approved myself and which I can vouch for as being worth the time and trouble.

One of the best variations from stewed blackberries and apples is elderberry and apple, using the two fruits in the same proportion as in the case of blackberries. Being a mere male I am not very expert in cookery, but I believe the apples are best stewed first and about the same amount of sugar is needed. The mixture is greatly improved if the elderberries are rubbed through a sieve.

Another excellent mixture is made by substituting bullaces for apples with blackberries. In some parts of the country bullaces seem almost unknown, though they are for cooking and preserving purposes one of the very best plums, and the white variety makes a very beautiful and delicious sub-acid jelly. Both the white and black bullaces grow wild in this district (Suffolk), the white being the rarer, but more common in cultivation. Being a sour fruit, they greatly improve blackberries, if mixed with them, whether as a mealtime sweet or in jam, and for this purpose the black bullace is best, as the stewed fruit is a much prettier colour when these are used. Some years ago we had very few plums and quantities of pears, and stewed pears became a drug in the market. Then a brainwave suggested mixing them to make the plums go farther. The result was that the pears lost their insipidity and took on the flavour of the plums. After the plums were over damsons and bullaces were tried and found better still. Then came a year when there was a big crop of sloes, and we tried them with the pears. I gathered a basket of sloes and some of these were tied up in muslin to keep them separate and stewed with the pears. When they came to table you could not tell, either by look or taste, that the pears had not been stewed with a liberal addition of good port wine. Sloes will keep, gathered, till the New Year and be none the worse for keeping.

Blackberries and rhubarb make a very good mixture both for tarts and for jam and I should say that elderberries and rhubarb would be equally good.

A particularly good preserve is wild crab apple jelly, especially if you can get the round red crabs which are not common in Suffolk. Cores and skins should be boiled with the fruit as the skins give it a pleasing colour and the pips improve the flavour, and the juice should be strained off through a jelly bag and 1lb. sugar added to one pint of juice.

Another good mixture is stewed apples and mulberries. This is an excellent way of using up any surplus mulberries which will not keep. T. H. DIP

NOTES FROM CONTRIBUTORS

AUTUMN FLOWERS.

THOUGH autumn-tinted foliage and berries are rapidly replacing the more brilliant colours of our garden flowers, there are a great number of beautiful plants whose flowering season is the present, and again a number grace the garden with their second crop of bloom during these autumnal days. The weather here has been vile throughout September, except for a few days in the first week and again in the last week of the month. Happily, these were open and sunny, the results being everywhere apparent. Among the roses here the varieties Betty Uprichard, Emma Wright, Independence Day, K. of K., Lady Pirrie, Mrs. H. Morse, Ophelia, Padre, Isobel and Mrs. Oakley Fisher have proved to be excellent growers and fine autumn-flowering kinds, but this year perfect blooms have been the exception rather than the rule. Planted through a border of Japanese iris, Gladioli Halley, Prince of Wales and others are forming groups of colour. Several of the primulinus hybrids have also given variety in colour, the best being Atalanta, Delicate, Orange Brilliant and Vanessa. Down in a deep gorge, but on the higher ground above the giant Gunnera manicata and its handsome neighbour Rodgersia tabularis—which are, during a season like the present, enveloped with a mist-like spray from the adjoining falls—Senecio clivorum with its thick leaves and huge corymbs of deep golden yellow flowers stands erect in spite of the many blasts. Along a partially shaded walk leading to the rock garden the large blue and white flowers of Geranium Wallichianum Buxton's Variety are particularly fine just now. Below the overhanging branches of a tall Tsuga Mertensiana a colony of Cyclamen europæum still in flower serves to remind one of still larger colonies of C. neapolitanum about to throw up their beautiful flowers in varying shades from pink to white, while the thick leathery leaves of C. Coum are pushing up through the thick carpet of needles shed by the towering hemlock. On a low bed near a drift of the tiny Astilbe simplicifolia Gentiana Farreri grows luxuriantly in the richest soil of the rock garden and produces hundreds of fresh trumpets daily during sunny periods. Though this particular bed was only planted with small plants from pots last spring, many to-day (October 4th) have as many as two dozen fully developed flowers and many yet to come. Large plantings of Erica vulgaris Alporti are very dense and rich and a complete contrast to the group of E. vagans St. Keverne. This variety has very choice clear pink flowers and is assuredly one of the best heaths ever introduced. In a border of asters—Michaelmas daisies—Cloudy Blue, Wonder of Colwall, King of the Belgians (lavender), Ethel Ballard and Snowball are outstanding of the Novi-Belgii section, while Aster Thompsonii, an Indian species, forms clumps in the foreground. Montbretia Nimbus, Queen Alexandra, Queen Adelaide, Queen Mary and Pageant are at their best in a warm border, with Lilium Henryi and L. tigrinum Fortunei giganticum as neighbouring plants. Growing among rhododendrons, Lilium auratum platyphyllum reaches about 7ft. in height with immense heads of huge flowers. This lily scents the whole surroundings. One other plant worthy of mention is Kniphofia W. Hucken. I do not know the origin of this "poker," but it belongs to the gracilis section and has long, tapering orange spikes. I first saw it in Ben Reid's nursery, Aberdeen, and the manager there spoke highly about its free-flowering character.—J. T. H., *Perth.*

GIANT MECONOPSIS WALLICHII.

I AM sending you a photograph of some Meconopsis Wallichii which were grown in these gardens. No doubt many readers will be interested to know of this lovely plant, which is quite easy to cultivate in a moist shaded position, being a woodland plant. The best way to grow it is to sow the seeds in March, in seed pans or in 6in. flower pots, the latter half filled with crocks, then fill up with a fine compost of leaf-mould, loam and sand, put into a frame or greenhouse; when the plants are large enough prick off into boxes in a good coarse compost, still keeping them in a frame; when they are about 1in. to 1½ins. high, pot into sixties and put them into a shaded frame. When 3ins. or 4ins. high, plant out in their permanent quarters; loosen the bottom roots a little before planting out. Plants will get away better if treated thus, and will not suffer from a dry ball. It is important that the plants

A FINE WOODLAND PLANT. MECONOPSIS WALLICHII.

should be kept growing and not allowed to get stunted in flower pots.

The bed should be dug to a depth of 18in., putting in some good loam and plenty of leaf-mould; plant firmly. As Meconopsis Wallichii is only a biennial, one must raise new plants each year to keep up the annual stock of flowering plants.

The plants in the illustration commenced to flower on July 4th and continued till September 16th; the plant on my left had 240 flowers, was 7ft. high; that on my right had 480 flowers, was 6ft. high and 3ft. across the lower part of the plant.—T. D. SARSONS, *Sussex.*

ROSE LA REINE TULIP.

THIS very taking little double tulip came to me as a present from my friend, Mr. Bull of Ramsgate, and in the covering letter he said he thought I would like it. That was three years ago. I liked it when first it bloomed, but I appreciate it more than ever now the original half-dozen bulbs have grown into a little mass. As a rule I do not care for double tulips, partly because they are unable to stand bad weather. Rose la Reine may be described as a "petit" or fairy double. Its wiry little stems bear the small flowers, without flinching, through any ordinary spring. They are such delightful flowers, but how can I say what colour they are when every visitor whom I religiously ask to name it says something different. It's a case of "Elizabeth, Elspeth, Betsy and Bess" who all took an egg from the bird's nest with five in it and there still remained four! Rose la Reine is a soft-toned indefinable red, quite unlike any other that I have come across. To me it appears to be a sort of rose, but it has been described as carmine and vermilion! The only way to settle the question is to get a few bulbs and see for oneself what it really is. Unfortunately, it is but little known and I cannot find it in the usual lists. Possibly Mr. Bull, Rathlin, Ramsgate, might be able to supply a few. It is a good increaser, so it is quite likely he has a little stock.—JOSEPH JACOB.

BRODIÆA IXIOIDES.

OF the numerous brodiæas in commerce the majority are not too long-lived in many gardens, and a good number of us have found to our cost that a large proportion of these fine bulbous plants do not live for many years under the conditions of our gardens. Of course, with many this is not the case, and they are to be envied who can cultivate these handsome plants satisfactorily and permanently. To see them at their best, by the way, they should spear through other herbage, as with many of them the stem is too lengthy for the size of the flowers, unless its apparent height is shortened by a fair-sized carpeting plant. One of the hardiest and best the writer has grown is that named B. ixioides, and the variety called splendens deserves special reference, as it is bolder and has larger flowers. I find, too, that the colour—yellow—of B. ixioides is appreciated, as it is not too common in bulbous plants flowering in early summer, as B. ixioides does. It is variable in height, and in poor, dry, hard soil I have had it only 6ins. or so in stature; but in richer and more open soil it has been as much as a foot high. Personally, I prefer to have it about 6ins. rather than 12ins., as then, I think, the handsome umbel of yellow flowers which crowns the slender yet stiff stem looks finer than when the plant is taller. As a hardy border or rockwork brodiæa I should recommend B. ixioides, and preferably its variety splendens. I have never tried it in grass, where it would, I consider, be highly attractive.—S. ARNOTT, *Dumfries.*

THE SOLDANELLAS OR MOON WORTS.

PROUD and happy is the gardener who can display to his friends a fine clump of the soldanellas with their wonderfully fringed blue flowers. Yet this is not a matter of such great difficulty if one will only begin in the right way and see that the plants never suffer from lack of water in dry times. The latter is a very important point, for the plant is an immense moisture lover and one cannot expect good results where this is lacking. The soil should consist entirely of fine sandy loam, in which the plants must be made very firm and the surface should be partially covered by half-buried stones. Too sunny a position is not desirable, one in which they get the last gleams of the setting sun being ideal. In spite of their love of moisture the soil should be well drained, and this is a particularly happy circumstance, because it enables the plants to be well elevated and thus better to display their wonderful flowers. The leaves are round, green and leathery; the flowers bell-shaped and beautifully fringed, usually one on a stem, but sometimes more.—SANDSTONE.

A Genuine Clearance Sale of

ENGLISH - GROWN ROSES, FRUIT TREES, BULBS & HARDY PLANTS

WE have bought the whole of the Land, Horticultural Buildings and Stock of the Penn Nurseries, near Wolverhampton, lately in the possession of Mr. A. S. Dunton.

The Stock, including many thousands of excellently grown Bush and Standard Rose Trees, we are now offering at about half current prices, to effect a quick and complete clearance of the land preparatory to development for building purposes.

Finest Grade English-Grown Bush & Standard Roses

The 2 Collections A and B for 20/-

It should be clearly understood that these trees are in every way, first grade. In their quality lies the heart of the bargains. In making offers of collections we reserve to ourselves the right to send varieties of equal value in place of any that run out of stock.

The 3 Collections A, B and C for 28/-

FRUIT TREES.

Full particulars of varieties will be ready by time this advertisement appears. Please send for details.
3 to 5 year old Bush Apples, Pears, Plums, etc., will be **3/-** each.
3 to 5 year Standards will be **4/-** each.
In the meantime here are two excellent offers of small fruits:
Black Currant, Boskoop Giant 3 year old, twice transplanted trees, **6/-** doz. Packing and carriage **2/-** doz. extra.
Raspberries, Lloyd George about 4ft. canes, **6/6** doz. Packing and carriage **1/6** doz. extra.

PRIVET.

Ever Green, Oval Leaf. Fine bushy plants:
1½-2ft. **3/-** doz. **20/-** 100
2-2½ft. **4/-** doz. **30/-** 100
50 plants supplied at the 100 rate.
Packing and carriage on orders value from 5/- to 7/6, **1/6**; from 7/6 to 10/-, **2/6**; from 10/- to 15/-, **3/6**; from 15/- to 20/-, **5/-**. Special carriage paid quotation for larger quantities than 100.

SHRUBS.

Packing and carriage paid on orders to value of 15/- and over. Orders to smaller value **2/-** extra for packing and carriage.
1 dozen shrubs in variety from this list at the dozen price per variety.

SIMPLE GARDENING

VIOLETS.

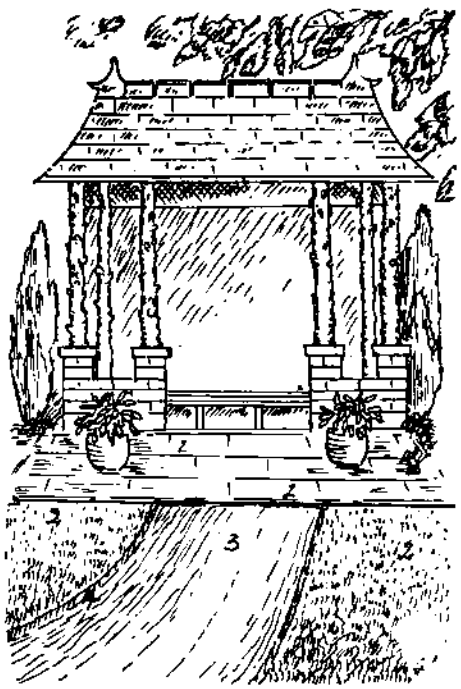
THE expert cultivator of these fragrant flowers will not hesitate to lift and replant clumps or young plants in the cold frame or unheated greenhouse at all times during the late autumn and winter months. The inexperienced cultivator, however, should not do this, but confine his attempts to lifting the plants during September and October. No doubt the majority of the plants are already in the glass structures, and if treated in a judicious way they will soon repay the owner with a wealth of blossom. Where sufficient frames are available, it is a wise plan to plant the single in one and the double-flowered in another, or in a series of frames, respectively, in each case. The plants are impatient of artificial heat or of undue coddling in every way. Too much heat and a too confined atmosphere result in harm; the former favours the spread of red spider and the latter damp. Only clear water should be applied, as the soil used should be rich enough to induce healthy growth throughout the winter. As the first warm days come a weekly spraying of the leaves with clear liquid manure will help the growth and stop the spread of red spider; clear soot water will also do this. Plants do not thrive well if the attendant treads down the soil between them while engaged in clearing away runners, yellow basal leaves or watering. Do not tread upon the soil at all. Ventilate freely, except in frosty or foggy weather.

WINTERING FUCHSIAS.

These plants are arranged and grown with great effect in our flower gardens during the summer months. They are suitable for use as standards, half-standards and for growing in cool quarters, and especially those borders that do not receive much sunshine. As they have served a good purpose and are, probably, great favourites, their safe wintering is a matter for due consideration. In the northern counties I have wintered the plants well in dry cool lofts—those immediately over potting-sheds and tool stores. In the southern I have found it sufficient to place the plants in sheds open at the front. The roots should be the chief care; many fuchsias grown in the open borders all the year round do not suffer from frosts, but those used in our summer-bedding arrangements are often killed by undue exposure to frosts. These specimens are more tender because they have received generous treatment and, probably, been started under glass in spring. The plants grown throughout in pots are the easiest to deal with. The unripe tips of shoots should be cut off and roots found through the hole in the pot or over the rim retained till spring. Place the pots almost close together and pack dry, short litter, fern or tree leaves between and over them so as to bury the rims 6ins. deep. Cover the branches in severe weather only. Do not apply water and remove to the greenhouse early in March.

GARDEN SHELTERS.

Garden shelters should be ornamental as well as useful; furthermore, they should be in character or keeping with the immediate surroundings. Example: a formal garden should contain a shelter after the style of the one shown in the



accompanying sketch, whereas an informal garden should contain a quite rustic shelter. Near the latter, clematises, roses, vines, honeysuckle and similar plants should be established; but close to the formal shelter large pots, tubs, boxes and vases or suitable shrubs would be in keeping. Bulbs, such as hyacinths, tulips and narcissi would look well, and although wallflowers, forget-me-not and similar plants may be grown in close proximity to the formal shelter, they are certainly fit plants for furnishing beds near the rustic one. The front of the formal shelter would look well "flagged" or paved as shown at Nos. 1, 1; Nos. 2, 2, may be grass or flower-beds; No. 3, path, gravel or paved; No. 4, edging in keeping with path and borders.

POTTING GREENHOUSE PLANTS.

Of course, we are all busy potting our bulbs — snowdrops, hyacinths, narcissi, tulips, crocuses—and reasonably expect a fine harvest of blossom in due time. But I wish now to refer to greenhouse plants in the autumn time. With a few exceptions I would advise cultivators who can only command sufficient heat just to exclude frosts to defer the potting of most kinds of plants, however pot-bound they may be, till about the middle of February next. Being well pot-bound will be in favour of a safe passage through the dull days. Calceolarias now in small pots should be shifted to larger ones forthwith. The plants will become stunted if left too long pot-bound. The repotting should be into pots large enough to permit of the fingers being inserted between the sides of the pots and the old balls of soil round the roots. Very firm potting is not required, water very carefully and guard against damp in the cool frame. Zonal pelargoniums should also be potted if necessary rather than run the risk of losing the basal leaves unduly. A high shelf in the greenhouse will be a suitable position and also for mignonette and schizanthus: both kinds of plants—those forward enough—will be benefited by repotting. Cinerarias and primulas will require a shift to larger pots and be placed on a front stage in the greenhouse. The plants will do better there than in cold frames.

STORING MANURES IN THE AUTUMN.

Not only organic manures, such as those from cow-sheds, stables and pig-stys, but artificials of all kinds require very careful storing during the winter months. I am quite sure that many readers will at once admit the fact that they have, in past years, fully exposed their heaps of manures to the weather for long periods. It means that, eventually, they wheel to their borders the husk or shell—the kernel, the best the manure contained, being washed away by the rains. All do not possess cool sheds in which to store such organic manures, but neat heaps can be formed with roofs like buildings and litter or similar material placed on them to form a thatch. Fowl and pigeon manures are obtained in less bulk and can be stored in sheds in heaps or in boxes and barrels. These manures must be kept quite dry; and during bad weather it is a wise plan to spend a little time reducing such manure to a powdery condition. It will then be of more value when applied to crops in spring and summer time. It is a mistake to apply fowl manure to land in the winter. Artificial manures, concentrated fertilisers of all kinds, obtained now and during the early winter, should be stored in very dry, cool sheds, always on boards, not on stones, bricks or earth.

GEORGE GARNER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Horseradish.—When an opportunity occurs, a portion of the bed of this root may be lifted and the roots graded and stored. The largest should be placed in ashes until wanted for the kitchen, and the smaller pieces laid in temporarily until the time arrives for planting. Horseradish well repays good culture, and a new bed is necessary occasionally.

Chicory.—A few plants should be lifted from time to time in accordance with the demand. Trim the leaves, and place the roots in boxes, working in a little soil as the operation proceeds. Hard forcing is detrimental to this useful salad, and a cellar or mushroom house will be quite warm enough. Darkness is essential.

Vacant Plots.—The successful gardener will now begin to make preparations for another season. All vacant plots can be dug deeply or trenched, the latter being preferable if the necessary labour is available. The surface of the ground should be left as rough as possible, then in the spring it will only need raking down to be ready for seeds or plants.

THE FLOWER GARDEN.

Planting Trees and Shrubs—The present is a suitable time for transplanting trees and shrubs, and if such work is carried out during the next month or so they will soon become established, and moreover will be in a better condition to withstand a dry summer. Where new trees and shrubs are required, a wise selection will be a departure from the usual laurel and privet. Flowering trees and shrubs ought to be chosen, especially those that bloom in July and August, also examples with ornamental foliage, while others characterised by their autumn tints should find a place in every garden where trees and shrubs are grown.

Alterations.—As time goes on the necessity arises for a few alterations or improvements in the flower garden and its environs, and where such work is contemplated it should be completed as far as possible by the New Year, unless extra labour is engaged. With the arrival of January the average gardener has plenty of work on hand, without such extra tasks as described above.

THE HARDY FRUIT GARDEN.

Root pruning.—The best time for this operation is during the next few weeks, and fruit trees that are making a lot of coarse, strong wood and failing to produce fruit require root-pruning. Small trees may be lifted and replanted on the same site, but for larger specimens a trench around the tree will suffice. This should be 3ft. or 4ft. from the trunk, and be of sufficient depth to get to the bottom of the rooting system. All strong roots are severed, and where they are of a thong-like nature with no root fibre they can be cut off near the base of the tree. Make a clean cut with a sharp knife, or later on suckers may be troublesome. Large trees may be partly pruned this season, and next year the circle can be completed. When the pruning is done, the soil is returned to the trench and made firm, but the fibrous roots are kept fairly near to the surface. For plums and other stone fruits, a portion of mortar rubble and lime should be added to the soil before returning it to the trench. It will be necessary to make the trees secure against high winds, by affording each one a stout stake, and this ought to be done directly the root-pruning is finished.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Cardoons, when grown in well manured ground, make luxuriant growth and should be further banked up with earth. This will prevent—to a certain extent—the heavy leafage from being damaged and broken when high winds blow.

Chinese Artichokes.—This root vegetable does not appear to be generally grown in Scottish gardens, and certainly one has to search a good many catalogues before such a name can be found among culinary roots offered for sale. The tubers are white or light straw coloured. In size and shape a tuber might be likened to four or five marbles somewhat jammed and joined together and tapering out at each end. The tubers are usually lifted as required, but a quantity may be taken up before severe weather sets in and stored in a deep box or small barrel among sand or fine soil.

Tomatoes.—In the late houses most, if not all, the plants will be rather bare and shabby-looking, so whatever tomatoes are hanging from the stems should be taken off and placed on a shelf in a somewhat warm house to ripen. The plants should then be cut down and thrown away. The structures when empty should be fumigated with heated flowers of sulphur, especially if disease or white fly has been troublesome; then the woodwork should be thoroughly scrubbed and the glass washed. Work such as this can be done in wet weather.

THE FLOWER GARDEN

Hardy Annuals, such as chrysanthemums, lavateras and nigella sown in the month of May on the hardy plant borders have grown and flowered splendidly. All flower-lovers, no matter how fastidious, appreciate the soft and delicate blue of the nigella or love-in-a-mist, but there is also a charm in the colouring of the annual chrysanthemums when such varieties as Evening Star and Morning Star are viewed in the sunshine of a fine October day. So soon as these annuals are past or become untidy they should be pulled up and cleared away. Other plants to be removed when opportunity offers are antirrhinums, larkspurs, nemesia, sweet peas, etc. Wire-netting pea-trainers and poles which have been used as sweet pea supports should be taken down, properly cleaned and placed in their respective storage quarters.

Chrysanthemums, although late in flowering, have made a fine display, and have supplied us with quantities of cut flowers. To make sure that a stock of plants will be available from which cuttings can be procured in the spring a number of roots of each variety should be dug up now and placed in cutting boxes, filling in old potting soil between the roots, especially of those varieties which may not have been lifted with good "balls," *e.g.*, a quantity of border earth about the roots. Sometimes chrysanthemum roots are merely set in the frames, and this method may answer where only a very few varieties are cultivated.

Rhododendrons, like fruit bushes, etc., benefit from generous treatment, and the present is a good time to apply a mulch of farmyard manure or leaf-mould. Any plants, too, which are being moved during the next two or three weeks should, especially if the soil is poor, be well supplied in their new stations with potting soil, old manure or leaf-mould.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Polygonatum multiflorum (Solomon's Seal).—This graceful plant is very charming for decorative work, its pale green foliage being very pleasing and distinct. Some time next month strong clumps should be placed in pots, afterwards plunging them outdoors until they are required for forcing. This plant is very useful during the spring months for conservatory or room decoration and also for furnishing a supply of cut flowers. Where required in quantity for this latter purpose, the roots should be packed closely together in boxes. If so desired the supply of this plant may be entirely home grown.

Astilbes, too, are very useful for conservatory decoration and may be potted up any time next month. Where required for house decoration, it is an advantage to get them into fairly small pots, but 6in. is as small as can be safely used. If intended solely for conservatory decoration, it is an advantage to have them in larger pots. 8in. being a very suitable size for the clumps that are usually purchased. In the larger sized pots much better results are obtained as astilbes are free rooting plants and demand ample supplies of water when they are growing.

Astilbe japonica (syn. Hoteia japonica) and some of its varieties are largely used for forcing purposes, their white flowers being useful for decorative work. A. Thunbergii is also used in the same way. There are now many new coloured hybrids of which some at least should prove useful for pot work. Two pink-flowered varieties, viz., Queen Alexandra and Peach Blossom, have been largely grown during recent years.

Spiræa palmata, with its brilliant coloured flowers is very useful for the same purpose and is treated in the same way as the astilbes. After potting they should be plunged outdoors until such time as they are required for forcing.

Brodiæas are more or less hardy in favoured situations, but being mostly natives of California they are impatient of damp during the winter. They are easily grown in pots, succeeding in any good potting compost, and are worthy of more general cultivation for the small unheated greenhouse. They should be potted up in pots or pans at this time and may be stood in a cold frame until they come into flower, when they should be removed to the greenhouse. Water should of course be carefully afforded until they have made a quantity of roots and have started to grow. Some of the best species for this purpose are BB. capitata, coccinea, grandiflora, Howellii, ixioides and volubilis.

Paper White Narcissus and **Roman Hyacinths,** if potted during August, should now be well rooted, and, according to requirements, a portion of them may be introduced to a warm house. Both these plants respond readily to forcing and come on quickly in a temperature of 60° to 65°, but in common with all plants used for forcing, it is wise to start them gradually in a lower temperature for a week or so before placing them in the forcing house.

Freesias should be given plenty of air on every favourable occasion, for if kept too close the growth will be drawn and weak. Suitable supports should be provided in plenty of time, for if the growth is allowed to fall over it never seems to recover properly. If so desired freesias may be had in flower at Christmas, but it is at the expense of quality and the well-being of the plants, for they are always best when grown under perfectly cool conditions. J. COUTTS.
Royal Botanic Gardens, Kew.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

About Antirrhinums and a Lily (F. W., Hull).—The antirrhinums were attacked by a fungus, commonly called black rot. Clear away all stems and roots and mix with the soil fresh lime at the rate of 6oz. per square yard, digging it in. Do not grow these plants nor annual asters in that border next year. The onions and leeks have split at the base and decayed, or decayed without splitting, owing to the excessive moisture in soil and air this season. The plants are too sappy, not matured in the normal way. Similar trouble may not arise for many years. The lily is, judging from the description, Lilium speciosum gloriosoides and should be treated in the same way as Lilium candidum.

Tropæolum speciosum (W. A., Dumbarton).—It is not common, but we have seen a young shoot growing from a flower-bud of this plant. Cut off and placed in a pot containing sandy soil and covered with a bell-glass, the shoot would probably root, but the probability is that all the flowers would be normal. If you take off several inches of the apple tree growths now, the remaining portion will thicken up and give better wood for winter pruning.

Crinums (T. D. H.).—The best time to lift and replant crinum bulbs is at the end of March, but should the weather be unfavourable at that time, it may be done with safety early in April. The bulbs require to be planted fairly deep in a rich loamy soil, with plenty of good drainage provided. A sheltered south border, preferably at the foot of a wall, is requisite for success with crinums in the open air.

TREES AND SHRUBS.

Berberis Darwinii Hedge (E. F. W.).—Plant 18ins. apart, and nip out the points of the young shoots freely for a couple of years to form a good foundation to the hedge.

Wild Garden (E. F. W.).—Your general scheme appears to be a good one. Laburnums, the Double Pink and Double White Rubus (brambles) and Spartium junceum might be added to the middle group also the wild roses. Hypericum calycinum and the vincas should find a place among the dwarf shrubs and the white birch is valuable in groups or singly.

Climbers for Arch (W. F. N., Birmingham).—The wistaria and Clematis montana are too vigorous in growth to confine to the arch you describe. Honeysuckles would be suitable. Plant Lonicera belgica (early red Dutch) and L. serotina (late red Dutch) one on either side, or if an evergreen is preferred, plant Lonicera flexuosa and L. Halliana. An alternative would be one of the jessamines, Jasminum nudiflorum, yellow flowers in winter, or J. officinale, white flowers in summer.

To Preserve Rowan Berries (Miss J. H.).—To preserve these berries whole, fresh and as natural as possible for Christmas decoration, gather when quite dry and place them in this dry state in glass jars, filling up the latter with dust-dry clean sand. Make the jars air-tight and store in a cool, dry cellar or similar place. An alternative way is to place the berries in the jars as above and, after making them air-tight, bury the jars in dry sand 6ins. deep in a cellar. In the open ground there is too much moisture or variation of it.

Shrubs for West Scotland (A. B. C.).—The following twelve flowering shrubs should prove hardy and satisfactory in a town garden in the middle west of Scotland: 1, Ceanothus Gloire de Versailles; 2, Viburnum fragrans; 3, V. Opulus; 4, Hypericum patulum; 5, Deutzia gracilis; 6, Potentilla fruticosa; 7, Spiræa bella; 8, Garrya elliptica; 9, Buddleia variabilis; 10, Skimmia japonica; 11, Pieris floribunda; 12, Rhododendron Pink Pearl.

Scotch Pine Twigs (A. H. H. M.).—These appear to be attacked by a fungus, possibly Hysterium Pinastri, but the material sent is insufficient for definite determination. In addition to a good spray, include a double handful of newly fallen needles, both from the old and young shoots, collected under the trees.

THE GREENHOUSE.

Iris tingitana (L. S. S.).—Iris tingitana can be flowered in pots in a cool house from which frost is excluded by planting early in October freshly imported bulbs obtained from some reliable firm. The soil should be light but rich, with some old decayed manure and made porous with lime rubble. After planting plunge the pots in ashes out of doors but do not cover them as the bulbs will begin to grow almost at once. When sharp frost threatens, they should be taken under glass. I. chrysographes requires rather moist, cool soil and sun. Holly can be struck from cuttings with a heel under a handlight out of doors though the cuttings root more quickly in mild heat.

ROSE GARDEN.

Rose Rust and Black Spot (M. S.).—The leaves sent indicate that the bushes are badly affected by the rust and spot, respectively. Cleanliness is essential now; all leaves fallen and shaken off should be gathered up and burned, also weeds. Spray both foliage and surface of soil with a solution of sulphide of potassium at the rate of 1 oz. to 2 gallons of water. Treat the plants in the usual way during the winter; prune severely in March and again spray with the sulphide solution just before the flower-buds form.

FRUIT GARDEN.

Treatment of Pears (Chelmsford).—Good late pears of first class flavour are: Duchess de Bordeaux, in season until March. Is a somewhat slow grower, but usually crops well. Nec Plus Meuris, in season until March; the fruits are small, but excellently flavoured. Buerré Rance, a good grower and cropper, the fruits being large and highly flavoured, in season December to March. Olivier de Serres, a good grower and cropper. Not striking in appearance perhaps, as the fruits are mostly flattened and apple-shaped, but the brisk musky flavour is very attractive; keeps till April. All these need to be grown well and generously treated—by mulching, etc.—and in some districts they need a warm wall to finish well. When not well finished, the flavour and quality may be anything but first-rate, and the same with all late pears. If only one late pear is to be grown, and a wall is not available, then perhaps the best kind is Josephine de Malines. The fruits are in season until May and are not difficult to keep in condition. It is a regular cropper and hardy grower, the fruits being smallish, greenish yellow, very juicy and deliciously flavoured. Bergamot d'Esperen and Zephirin Gregoire are both good late kinds too.

KITCHEN GARDEN.

Rust on Celery (G. C.).—Celery plants, generally, have been much infected with rust on the leaves this year. It is a fungus carried through the seeds, and cultivators should obtain a guarantee from the seedsman that the seeds have been duly treated. Sprinkle dust-dry lime on the foliage now after removing and burning the worst ones. Plant in another part of the garden next year, lime the ground in winter, use soot in spring and Bordeaux mixture on the leaves as a preventive in the summer.

Club-Root (F. B.).—A sour condition of the soil, the free growth of charlock on the ground into which it has from time to time been dug and the absence of lime in the soil, also the cultivation of these plants year after year on the same plot will result in club-root. The remedy will be obvious. The spores rest in the soil for several years. One application of lime is not enough. It should be applied yearly at the rate of 6oz. per square yard and soot in early spring at the rate of 1 peck per square rod.

MISCELLANEOUS.

Various Questions (J. M. G.).—Yes, if the narcissi referred to were allowed to mature their foliage, the bulbs should flower again next year. The bulbs may be left in the ground for another year, but if it is necessary to lift the bulbs, this should be done after the foliage has died. Tradescantia virginica and T. cærulea belong to the same section. Both Potentilla atrosanguinea Gibsoni and P. nepalensis Miss Willmott require the same cultural treatment.

Nasturtium Seeds (E. G. C.).—We have never heard of nasturtiums being made into jam. For pickling, the seeds are gathered when quite young and a small proportion of very small flower-buds mixed with them. Dissolve 1½oz. of salt in a quart of pale vinegar and put in the green seeds and tiny flower-buds day by day as they come to the proper state. It is all done cold—no boiling.

Cuckoo-spit (Miss H. C.).—This insect is known also by the names of froth-hopper, frog-hopper and froth insect. It sucks the sap from the plants, and the frothy matter is the excrement. The larva is here referred to. A solution of Sanitas syringed on the plants weekly will act as a preventive, and should be used early enough in the spring. There are directions on each bottle of Sanitas to enable the user to mix the liquid. A suitable strength will kill the larva if any are found on the plants.

Garden Rubbish (Enquirer).—The ashes from leaves, twigs, trimmings of all kinds and weeds are very beneficial for practically all garden crops. The best way to deal with such rubbish is to build a refuse burner in a corner of the garden. The burner is easily made by first forming a hole 1ft. deep and 3ft. across; a single-brick wall is then built round the hole to a height of 2ft.—mortar is not used, and spaces 2ins. wide are left between the bricks. On one side, near the ground level, an opening 1ft. square should be left for convenience in lighting the fire. Place a few old iron bars across the hole in the ground for the rubbish to rest upon. A draught will thus be ensured. The ashes should be kept in a cool dry place till required for use from time to time. Wet ashes lose 50 per cent. or so of the potash. The lily stems should be allowed to dry before being cut down.

Names of Plants.—(Insignis).—1, Euryops virgineus; 2, Sedum sarmentosum variegatum; 3, Lindera glauca; 4, Teucrium Chamædrys; 5, Olearia macrodonta.

WE WOULD ASK OUR READERS TO REMEMBER THAT "THE GARDEN" IS PRODUCED FOR THE BENEFIT OF ALL GARDENERS. WE ARE ALWAYS PLEASED TO CONSIDER ARTICLES OR NOTES ON ANY HORTICULTURAL SUBJECT. WE ARE ALSO HERE TO ANSWER QUESTIONS.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

IMITATING NATURE

MY article the other week on labels has obviously caused a considerable amount of interest from the number of letters which have been received on the subject. Several will be found in the Correspondence pages of the paper, but one I am quoting in this editorial, as the writer has introduced another debatable point which affects the ethics of gardening. He says—

I read your leading article to-day with sorrow. I refrained, with difficulty, from joining in the correspondence of a few months back, but now I must write—or bust.

You say "labelling is a necessity for all who aspire to rise above the beginners' class in gardening." Surely you meant to say "labelling is a necessity for the beginners' class."

To me labels in the garden are *anathema*.

The rock gardener endeavours to persuade himself that he is imitating nature—a presumptuous supposition—and you endeavour to persuade him that he must label his beloved friends.

So we should (and *do*, unfortunately) have to endure the dreadful sight of a "mountain side" or a "moraine" or an "alpine lawn" stuck all over with horrid little bits of stick or zinc, or celluloid; spoiling the natural appearance of the garden, advertising the gardener's lack of memory, or, still worse, indifference.

My rock garden is small, but I am thankful to say I have over two hundred children therein—none is labelled and none is forgotten—and I should think shame of myself if I thus advertised my carelessness and spoilt the natural appearance of their home.—GILBERT WHITE.

Now, apart from the rights and wrongs of labelling—and I should like to state here that our correspondent must have a very remarkable memory, for it is impossible to name many of the saxifrages, sedums, sempervivums and primulas when out of flower without a botanical examination—this letter brings to the fore the very debatable question whether any garden should imitate nature.

First let us take the concrete side of the matter. Where in nature, except in a few particular spots to be counted on the fingers of one hand, can you find twenty different plants, let alone two hundred, growing side by side within an area of a few yards? Plants from their nature are gregarious and there is no room for numbers of species. From my own experience I know only of one case of a solitary plant in an area and that was Viburnum Wardii; I believe that Rhododendron auriculatum was also found in a solitary state, but these are examples which only prove my point, for they are so noticeable as to remain fixed in my memory, and yet in a rock garden, and particularly a small rock garden, large colonies of the same plant are the exception, however desirable they may be.

This, however, is a minor point; what is important is that it is impossible in most gardens to imitate natural conditions under which a plant will flourish. As the main object with most of us is to gain the best results from plants under cultivated conditions, it is obvious that cultivation, and so results is the most important thing in the modern garden. Naturally we try to show off our plants to the best advantage and to show them off in something approaching natural conditions, but to imitate slavishly a mountain side, or an alpine lawn, is to court disaster.

The æsthetic point of view is just as important. Half of the enjoyment in seeing plants in their native element is because they *are* in their native element. We are on holiday when we see them, they have a worthy background, we are exhilarated by the fact that they are not in a garden. Even then some of their natural situations are not perfect. No one could call a moraine beautiful. It is a pebbly place that makes a noise like a stone crusher when you walk on it—but it happens to be the home of some very lovely plants. One does not manufacture a moraine in the middle of the rock garden to look at, but to imitate conditions under which these particular plants will grow.

In the short space of this article it is impossible to write at the length which the subject requires, but surely an ordinary garden is not designed to imitate nature as our correspondent suggests. We do try to make our gardens appear natural, but natural implies a different meaning from "imitating nature."

But, after all, this argument is settled by the simple statement that a garden is no place for the extremist. There is always a happy mean to be found where the cultivation of plants is satisfactory, their setting is satisfactory and the general picture is satisfactory. It is those who do not try the impossible who are most successful, and Nature is an impossible being to copy.

Incidentally, I should like to point out that I disagree absolutely and entirely with our correspondent's view upon labels. Ordinary people are not gifted with his memory, and for most of us plants are the important thing, not the garden. There is nothing so annoying as to forget the name of a plant when one is asked. E. H. M. C.

APPLES AND PEARS

BY EDWIN BECKETT.

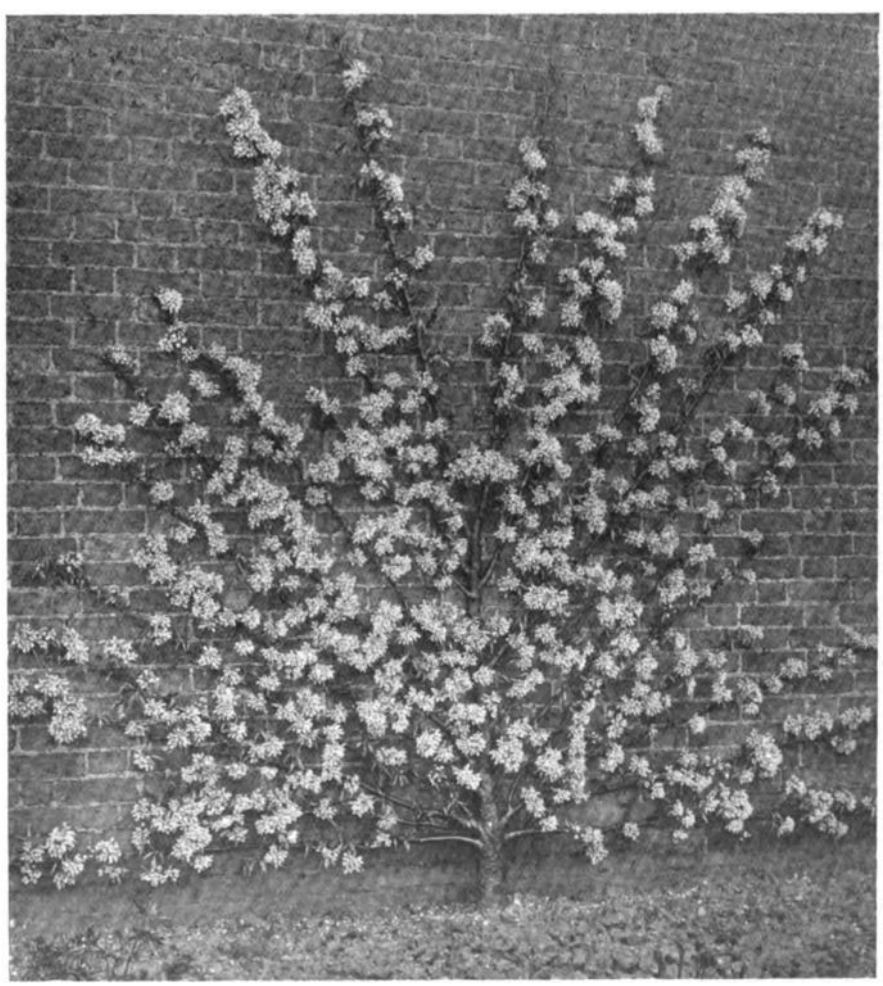
IN THIS ARTICLE MR. BECKETT BRINGS FORWARD SOUND ARGUMENTS FOR THE GROWTH OF MORE HARD FRUITS IN THIS COUNTRY. HE IS STRONGLY IN FAVOUR OF EVERY FARM, GARDEN AND ALLOTMENT PRODUCING ITS QUOTA OF FRUIT.

WHEN considering the many aspects of the fruit-growing industry in this country, one is forced to a definite, though disappointing conclusion in one direction, to wit, that the efforts made in the way of raising hard fruits are not of the magnitude that this important branch of horticulture deserves. True it is that competition from abroad, particularly from the Colonies, is severe, as witness the large annual imports; true also that, probably, economic and climatic conditions are more favourable to our competitors; yet the fact remains that we ought to make greater endeavours than we do, particularly with regard to apples and pears. As this number of THE GARDEN is to be partly devoted to fruit, it will perhaps be as well to consider the problem from one or two directions in which progress could well be made with fair rapidity, and with profit to the enterprising. These may be summarised under the general heading of Home Growing, of which we will briefly consider two or three branches.

It is not so many years since a well furnished orchard was considered an important part of the routine of a well managed farm with an all-round programme; nowadays, alas! this important feature is more frequently missing than in evidence, and the farm orchards that one does see while travelling up and down the country are too often ill attended and lacking in quality. So much for condemnation in one quarter. Surely our British farmers are losing a fine chance of a profitable side line, one that would prove an ideal way of employing some of those minor waste areas close to the majority of farm houses that are generally only used for scratching grounds for domestic fowls, and which could still serve this purpose while carrying a proper burden of apple and pear trees, to say nothing of plums and similar soft fruit allies. If the farmers would only consider more seriously this suggestion, it is certain that they would gain an offset against those otherwise bad seasons so frequently bemoaned by them. During the past few years it has been my pleasure to arrange such orchards at farms in and around this district, and the results that are now being attained are splendid, despite the comparatively short time since the efforts were started, and the promise they hold for the future is magnificent.

The same thoughts can well be digested by the increasing, and, it is hoped, ever increasing, army of smallholders, to whom this should also prove a good source of livelihood.

Now let our remarks be directed to another large group, the workers of allotments, the tenants of cottages with reasonable-sized plots attached thereto, and the possessors of small gardens. These, too, also neglect their opportunities frequently, for it is really surprising how few gardens carry any fruit at all; and again, what a good quantity can be got into a comparatively small space. Methods and forms of planting will be dealt with later, the effort for the moment being the urging of all to consider seriously the call to do more growing of these beneficial fruits. Allotment committees, forward for one moment, please! Are you doing all that you can in this direction? Looking at the various allotment grounds, the answer cannot be in the affirmative, so, where you have a reasonable security of tenure on your areas, see to it that each plot carries its fruit tree for the benefit of the plotholder, and guard, tend and treasure them well, for they will all aid this country in keeping money at home instead of sending it abroad. So far as the small garden owner is concerned, he also can follow the lead. Some do, to a surprising extent, for only this past week I witnessed a remarkable instance where, in a town front garden of only a few feet depth (backyard practically nil!) a standard apple tree stood, carrying a heavy burden of good-looking fruit. What an example it might well prove to the local municipal authorities, who, incidentally, had planted up scores of their roads with the rather uninteresting Cornish elm. On the Continent (particularly, I believe, in Germany), town-governing authorities do not hesitate to line out their roads with fruit trees, which the inhabitants carefully guard from depredation; so why should not our "City Fathers" take a leaf out of the book of those thoughtful householders, and plant fruit trees for a change? Apart from the utility point of view, what could be more beautiful in flower than apple and pear trees in spring? Let us hope that this may act as a hint to town-planning experts!



ANYONE WITH A WALL TO HIS GARDEN CAN HAVE A TREE SUCH AS THIS. IT IS WELL TRAINED AND AT FULL BEARING POWER.

Having now decided that increased growing can and will be of all-round benefit, let us consider some of the prime needs of such effort. The most important point is to settle just what varieties do well in particular neighbourhoods, for this rule of certain

Digitized by Google

districts suiting certain varieties apparently holds good throughout the bulk of horticultural subjects, from the potato (a very striking example) to the pear tree. It will be found with fruit trees for instance, that where, say, a Worcester Pearmain apple will do excellently in one locality, fruiting well and of good quality, in another it may prove a miserable failure year after year, both in quality and quantity, and county authorities should seek permanent data on this point for ready reference by the public in their areas, and keep such information up to date. The first advice, therefore, to those who would go in for apple and pear growing is to ascertain the best sorts in their own neighbourhood. This particularly applies in regard to old varieties. It is very pleasant to be able to point to a young tree of a new variety, bearing a few fine fruits in the vigour of its youth, and proudly say, "There's a fine tree of Xmas Pippin, a new sort, only sent out in 1922"; but age, after all, is the supreme test, and though, almost annually, controversies arise on the lines that there are too many varieties, yet, in some of the bad years, the supposed redundant sorts prove their value over and over again by yielding under most adverse conditions, and especially has this been the case this season.

Point No. 2 is the source of supply, and here the advice is principally for the small grower, for whom THE GARDEN has been doing so much recently. Do not buy an apple tree off a street vendor's barrow, merely because it is low priced (not necessarily cheap in the end!), but get your trees from a reliable source—one which you can depend on first-class material, true to name—for, like most other things, there are fruit trees and fruit trees!

We will make the third consideration the sort of tree to select, though perhaps this should have been No. 2 on the list. Limited areas call for smaller-growing forms, and according to space available so can be chosen standards, half-standards, bush or pyramid forms, and lastly, trained trees and cordons. A small garden could, perhaps, carry three or four nice shapely bushes, or pyramids, where one large standard might prove far too spreading; or, again, another area could well support a couple of good trained trees along a path or against a wall or fence, or perchance six to a dozen cordon specimens. At Aldenham, where our soil is cold and heavy, some of our most prolific bearers among pears are trained trees and cordons.

Mention of soil brings us to our fourth detail—planting. Consideration of this is too frequently neglected, for all care should be used over it. Roots, for instance, should be examined for any that are damaged, and such should be removed by a sharp knife-cut made above the damaged portion, cutting from the underside upwards and outwards. The planting position should be well prepared by trenching or digging, a very necessary point in heavy ground, for proper drainage for the escape of surplus water is essential, and thus the hole should be got ready for the reception of the plant, allowing ample room to spread the roots out level and carefully. When this has been done and the tree held in position, cover the roots with the finest of the soil, working it well in round the roots, and then add the rest of the soil, tread firm, and finally place the firm stake to which to tie the tree in order to prevent it swaying in the wind, a happening which would unsettle and loosen the roots, to the harm of the tree. Do not plant too deep, a very necessary caution the heavier the ground. It is an error frequently made but the endeavour should be to keep the roots well up to the surface. Often good trees are badly handicapped and even killed through too deep planting. Should the site be very heavy and inclined to waterlog, the trees would be better planted on the mound system, if possible—that is, roots placed just above surface level and soil banked over them in mound shape, thus greatly assisting drainage in case of inundation.

Pruning, a very necessary part of a good tree's career, is something that must be learned according to the varieties grown. The final point to be urged is, do not forget to give the trees a good drink during a dry spell, for an apple or a pear tree requires this just as much as any other vegetation, especially when carrying its fruit. If neglected at the latter time—well, look out for the fallen fruit round the foot of the tree, for that will be the result of such neglect.

Let us again press the necessity of growing more fruit, particularly hard fruit. It matters little whether you possess a walled garden, a plot, or an allotment, there is always room for a fruit tree or two. It is not so necessary for a farmer to copy his brethren in Ontario—where they rely chiefly upon three things for the family income: hogs, cheese, apples—for such an arrangement is impossible in many parts of this country owing to climatic differences, but it seems to us ridiculous that many a family, who live in the country and have a sufficient area of ground, journey to the nearest town and bring back imported fruit on which to regale themselves, and yet this is a common occurence just now. Perhaps many of us are allowing our palates to be dulled by eating inferior fruit, but there is nothing in the world to equal a good home grown apple or pear.

IT IS NOT SO MANY YEARS AGO THAT A WELL FURNISHED ORCHARD WAS CONSIDERED AN IMPORTANT PART OF EVERY FARM. IT SUPPLIED THE FAMILY WITH FRUIT WHICH IS NOW IMPORTED FROM OVERSEAS.

PRIMULAS WHICH ARE OUT OF THE ORDINARY

A FEW PRIMULA SPECIES WHICH REQUIRE DIFFERENT METHODS OF CULTIVATION FROM THOSE USUALLY MET WITH IN GARDENS. THEY ARE ALL WORTHY OF BEING GROWN.

FROM the large and beautiful family of primulas, I describe several members below, which for various reasons are uncommon in gardens, principally on account of their being rather opposed to the conditions, climatic and otherwise, they are subject to in this country. Primulas, generally speaking, are of a good temperament, and for a certain amount of care give ample enjoyment and satisfaction as the result. But it is with those species that need coaxing that I intend to deal, because I certainly believe they are worth the extra trouble and patience that is so necessary for their well being.

PRIMULA CHIONANTHA.—Here we have an attractive Chinese native belonging to the "Nivalis" section, a plant of moderately easy culture in a moist rich loam. Its leaves are long and narrow, of a dull green, the underside is heavily coated with golden meal, as is also the handsome flower spike. The flowers are large, starry and white, deliciously fragrant and are produced very freely in whorls, the spike, carrying several tiers at close intervals, runs up to a foot or 18ins. high. Seeds are plentiful and germinate readily. I believe partial shade to be suitable, although this summer (if I may term it such), I was surprised to see a most lovely specimen, with a flower spike in seed, nearly a yard high, growing on a hot sunny slope.

P. FORRESTII is a species that is very uncertain about coming through our winter, although it will and does do if it is afforded the most ideal conditions. Winter wet, which it simply detests, is the only knotty point in its cultivation, so, to avoid this as far as possible, it should have a perfectly drained soil and a hot sunny crevice. It is a limestone plant, coming from the limestone cliffs of western China. In appearance it resembles the polyanthus, with stout crinkled leaves and a sturdy erect flower spike 9ins. high, atop of which its flowers are borne in a dense head of an intense orange colour, and particularly notable for their fragrance. Similar in habit to this, we have a yellow version in P. rufa, of a more hardy constitution and easier of management.

P. NUTANS, FROM A PHOTOGRAPH TAKEN BY GEORGE FORREST IN CHINA.

P. WINTERI.—When practically very few flowers exist in the open, that is in mid-winter, this fine species appears at its best, carrying, for several weeks, quantities of sumptuous, large, golden-eyed lavender blossoms, singly on stems 3ins. high, emerging from a compact mass of handsome pale green leaves in the shape of a rosette. Both leaves and flower stalks are enveloped in fine white meal. The plant requires a moist, shady position, protected in winter from excessive overhead wet in a compost of fibrous loam, peat and sharp silver sand; good drainage is also essential. Summertime is the critical period for this plant, as it falls an easy victim to the red spider, so that a position that is cool, moist and shady in summer is the one to be selected. It makes an ideal alpine house plant where it can remain throughout the winter, turning it out into a cool corner during the summer.

P. REIDII has the reputation of being one of the loveliest of its race, although it is by no means of easy culture, requiring abundant moisture during the growing season and equally as little in the resting season. A gritty mixture of peat, leaf-mould and sand, including chips, should prove beneficial to the plant. It is of a dwarf habit, with oval leaves clad with silky hairs and powdered mealy flower stems not exceeding 6ins., from which dangle its large ivory-white, bell-shaped blossoms. Also a good plant for the alpine house.

P. LOCZII.—This Tibetan species is desirous of moist, spongy compartments of leaf-mould, peat and sand. It succeeds well at the edge of a bog, failing this a half shady aspect would be advisable, but it yields fairly readily to cultivation and where it is happy soon makes a mat. In flower it resembles P. farinosa or P. frondosa, yet it is devoid of farina and makes a small rosette of bright green leaves, from which it throws out numerous runners like a strawberry. These are usually a few inches long, quite prostrate, the tips open out into separate rosettes and take root readily, so that propagation is an easy matter once the plant thrives.

P. LUTEOLA.—Although this species has been in cultivation over half a century it is rarely seen in gardens, for some unknown reason, not that it is hard to grow, nor because it is not beautiful. Its leaves are long and narrow, toothed and free from meal, and the flower stalks are about a foot high, headed with a round mass of most lovely citron-coloured blossoms. A rich compost of fibrous loam is most suitable, in partial shade where coolness at root is catered for; there the plant should easily thrive and form a clump, which, as required, may be divided with advantage. It is a perfectly hardy species from the Caucasus.

P. SECUNDIFLORA is a charming Chinese species, suitable for a cool, well drained position in half shade, with a deep rich mixture of peaty loam. Its flowers are of a deep port-wine shade, with a still darker purplish bloom on the outside. The flowers are large and bell-shaped, as in the better known P. sikkimensis, and are produced in a loose head on a 12in. stem. The leaves are handsome and erect, long, narrow and finely serrated, of a deep glossy green colour. Seed is profusely set and germinates readily.

P. NUTANS.—A most lovely introduction belonging to the grape hyacinth tribe, with long, oval leaves covered with short, fine hairs, and flowers of a deep violet and of a large type. A cool, deep pocket of peat, leaf-mould and sand in semi-shade should suit its requirements. Up to the present it is very little known, but no doubt there is a future before it.

F. BARKER.

WINTER PRUNING OF SHRUBS

THESE NOTES WILL BE OF GREAT ASSISTANCE TO OUR READERS WHO WISH TO IMPROVE THE APPEARANCE OF THEIR SHRUBS. PRUNING DOES NOT MEAN THAT THE PLANTS LOSE THEIR INDIVIDUALITY.

THE increase in the popularity of the outdoor garden during recent years is nowhere more apparent than among hardy shrubs. What a contrast the shrub beds and borders in some large private gardens and public parks provide to-day when compared with those of twenty-five or thirty years ago. We also find the interest in choice flowering shrubs extending very widely in small gardens. Uninteresting borders of privet, laurel, aucuba and perhaps a lilac or two are giving place to showy deciduous and evergreen flowering shrubs.

Following in the wake of these extensive plantings in a wide variety of shrubs is the necessity for an intimate knowledge of their nature and habit. At no time is this acquaintance more important than when pruning has to be done. The size, habit and season of flowering must each be considered.

Taken in a general sense, the object in pruning flowering evergreen shrubs is different from that of flowering deciduous shrubs. There is no necessity, for example, to prune the evergreen berberis, B. Darwinii or B. stenophylla and the named hybrid rhododendrons to improve the size and quality of the blooms. If they need pruning at all, it is usually to prevent the bushes growing too large for their positions. In such cases it often means extra hard pruning in spring and sacrificing a season's flowering.

In a broad sense the deciduous flowering shrubs may be divided into two main groups: (1) Those that produce their flowers on the wood made the previous year and (2) those which flower on the new shoots of the year. In cleaning and forking through the borders and beds of shrubs during the winter these two types or groups of shrubs will require quite different treatment. The best time to prune most of the shrubs constituting group one—which includes deutzia, philadelphus, kerria, diervilla, Cytisus purpureus, forsythia and cydonia—is immediately after flowering. Assuming this was done, these will be passed over as the winter's work proceeds, unless a shoot here and there needs shortening to maintain symmetry or because they happen to be encroaching on a neighbouring bush.

Among the most important families of hardy shrubs to be pruned during the winter are the late summer and autumn flowering spiræas and ceanothuses, Hydrangeas paniculata and arborescens, colutea, Buddleia variabilis, Tamarix pentandra (Pallasii var. rosea), Spartium junceum, Cytisus nigricans and numerous shrubby clematises.

Just as the pruning of roses is left until the end of March or early April to defer the growth of new shoots which might be damaged by frosts, so we usually leave the pruning of any shrubs at all tender until March; notably the varieties of ceanothuses and hardy fuchsias, the growths of which are generally killed back some distance in most winters.

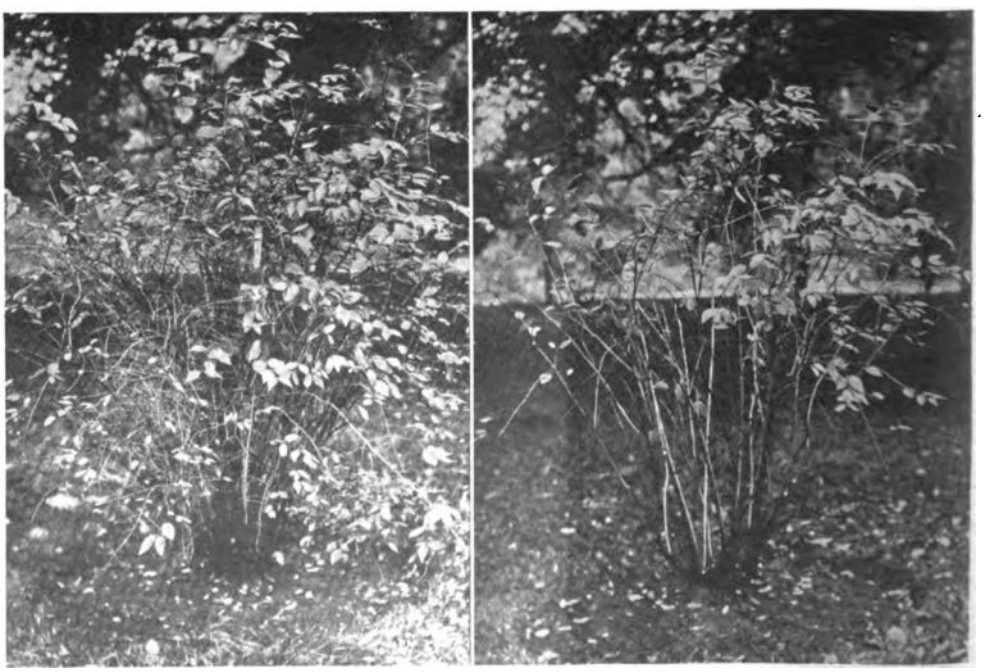
There is also usually a certain amount of what may be called general pruning and thinning to do. The ideal borders and beds of shrubs must not be crowded. Hence without harm to the individuality of a shrub it may be necessary to curtail a little the size of a plant and to regulate the shape with the object of preventing encroachment on a neighbour.

Almost equally impressive as the wonderful collection of shrubs at Aldenham to visitors, must be the very close attention given to their pruning. This part of the work I know the Hon. Vicary Gibbs considers very important.

There is another class of shrubs the pruning of which we are apt to overlook. I refer to the cotoneasters, the viburnums, the rose species and the berberises grown for their fruits. These cannot be pruned after flowering because we leave the branches to mature the attractive fruits. In winter, hard pruning after the fruiting period would mean the removal of the best flowering growths. Pruning with these and similar shrubs consists in the thinning of the bushes by the removal of the oldest growths, shortening also if need be a few of the longest shoots to improve the shape and appearance of the plants. In some gardens stress of other work in summer prevents adequate attention to the removal of old flowering wood at the proper time from the philadelphuses and diervillas, for instance, this also being done during the general clean up in winter.

In reviewing the most important shrubs requiring definite methods of pruning during the winter and early spring, it will facilitate reference to take them in alphabetical order.

The best forms of Buddleia variabilis are among the most showy late summer and autumn flowering shrubs. The largest flower panicles are obtained when the previous year's growth is pruned fairly hard back each winter, giving vigorous new shoots the following summer 5ft. to 6ft. or more in length. In sheltered sunny positions two species of caryopteris are pretty in autumn, C. Mastacanthus, an old favourite from China with violet-blue flowers, and C. tangutica of quite recent introduction with rather darker flowers and a more spreading habit. Considerably shorten the previous summer's shoots with the idea of securing vigorous new growths. Cultivated as bushes, the named hybrid ceanothuses—Gloire de Versailles is the best known—mostly of Continental origin, are particularly showy planted in groups along the fronts of sunny shrubbery borders and lawn beds when not much exposed to winds. With these, again, fairly liberal annual pruning and thinning, removing weak wood, is desirable. Cultivated as wall shrubs when the plants have covered the allotted space pruned specimens give much larger inflorescences. Though only of a semi-shrubby character, the heracleæfolia or tubulosa group of clematis are usually grown in association with shrubs. In addition to typical C. heracleæfolia, C. stans and the beautiful C. Davidiana, a number of hybrids have been raised on the Continent by M. Lemoine of Nancy. The pruning consists in cutting back the growths to firm stems; this in severe winters usually means down to the ground.



A PHILADELPHUS BEFORE AND AFTER PRUNING.
In this case pruning should take place immediately after flowering.

Digitized by Google

The bladder senna, Colutea arborescens, is a fairly frequent occupant of the shrubbery, and unless regularly pruned soon becomes tall and unwieldy. Most of the cytisuses (brooms) only require stopping or pruning in a young state to make bushy plants. One notable exception is Cytisus nigricans. This flowers from midsummer onwards. When pruned before new growth commences in spring the bushes develop a wealth of long terminal racemes of yellow flowers. In few hardy shrubs is the value of hard pruning more evident than in the Hydrangeas paniculata, the variety grandiflora and arborescens var. grandiflora. Spurring back the previous year's shoots to within two or three eyes of the old wood induces the production of vigorous new shoots with large flower-heads. All the shrubby hypericums are improved by annual shortening and thinning out the weak shoots in winter.

In sunny positions and well drained soils the varieties of the tree lupin, Lupinus arboreus, are useful shrubs to flower in June and July. The quality of the blossoms is very considerably improved by liberal shortening of the branches before new growth is due to start in spring. The golden elder, Sambucus nigra var. foliis aureis, so much used in shrubberies for the rich golden colour of the leaves, attains its greatest beauty with hard pruning.

The loose straggling habit of Spartium junceum is overcome by a free use of the knife, especially when the plants are young. In no family of hardy shrubs is the value of winter pruning more evident than in the summer-flowering spiræas of the japonica group, which includes Douglasii, Menziesii and salicifolia, also the Sorbaria section to which belongs Aitchisoni, arborea, Lindleyana and sorbifolia. Pruning of the first group consists in shortening the vigorous young growths, the removal of old flowering wood and thin wiry twigs. The Sorbaria section with big woody stems should have the flowering shoots of the previous summer spurred back to within two or three eyes of the old wood. Tamarix pentandra, perhaps more familiar to many readers as T. hispida æstivalis or T. Pallasii rosea, one of our most valued autumn shrubs, should have the stems cut back to 1in. or 2ins. from the old wood each winter.

HOW HYDRANGEAS AND SIMILAR SHRUBS SHOULD BE PRUNED.

The general trend of these remarks points to two main objects in pruning: (1) To improve the quality of the flowers; (2) to maintain shapely bushes. These two lead to a third, and the most important from the spectacular standpoint, the healthy and attractive appearance of the shrubs in the garden borders and pleasure grounds. A. OSBORN.

BORDER CARNATIONS FOR AUTUMN PLANTING

IT is generally agreed that autumn planting of border carnations gives the best results. The plants have a long period in which to settle down and become established, with the result that in the quick-growing period of early spring they are ready to take advantage of favourable weather conditions. The border carnation is hardy, and as most varieties will stand an ordinary winter unprotected, there should be few casualties if certain essential details of soil preparation are carried out.

Some soils are ideal for carnation culture, notably those which might be termed light loams. In my garden I never have the slightest difficulty in rooting carnations in the soil taken from the garden without the addition of any sand, and with the exception of the loss of an occasional plant through a ground pest, such as wireworm, the plants make strong, healthy growth and flower freely. In such a soil it is easy to grow carnations, but even in these favourable conditions I find that a little extra care in the preparation of beds and borders makes the difference between ordinary results and flowers of higher quality.

In stiff, clayey soils it is necessary to incorporate substances that will give the medium a more porous character. Strawy manure in the lower spit and the addition of sand, road grit, mortar rubble or brick rubbish will help to keep such soils from becoming water-logged, which would be fatal to success.

On the other hand, a soil that is of too sandy a nature requires building up, and a liberal supply of well rotted manure, bone-meal and refuse from garden fires, which is always rich in potash if used when dry, will be found to be beneficial.

It cannot be too strongly emphasised that carnations are lime-loving plants! A liberal supply of lime should be worked into the beds when these are being prepared. It may take the form of mortar rubble, spent lime or chalk, but it is essential that there should be a plentiful supply of calcium compounds in the soil if carnations are to thrive. Not only is lime necessary for the well-being of the plant, but it is also useful in keeping the soil from becoming sour, aerating it and setting free the necessary food supplies that are available in the manures incorporated in the soil. Mr. Montagu Allwood tells me that he is assured that the majority of failures that arise in carnation culture would never occur if growers would realise the advantages arising from the correct usage of lime. He is also of the opinion that carnations abhor leaf-mould, and that this should never be used in their culture.

Having chosen a suitable site for the plants, which should be in an open, sunny situation if possible, and as much sheltered from the winds as can be obtained, soil preparation should commence at once, if this has not already been done. The ground should be dug or forked to a depth of from 12ins. to 18ins., as circumstances will allow, keeping the animal manure well worked into the lower spit and retaining the top layer of surface soil by the method known as bastard trenching. To bury the top layer and bring the poorer sub-strata to the surface would do more harm than good. Stiff soils soon become ready for the reception of plants after trenching is completed, but lighter soils will require more time to settle down or they will need to be trodden firmly. Unless there is a firm root-hold for the plants they will not make satisfactory progress, either in the initial stages of growth or later.

If plants have been layered at home, their removal to permanent flowering quarters is a simple matter, and a portion of soil can be taken up with each rooted layer so that there is practically no check in the removal. When layers are obtained by post they are usually packed in damp moss, and at this season of the year will suffer no injury for several days. It is, of course, advisable to unpack and plant out on arrival, if possible. If the site has not been already prepared, they can be potted up and kept in a greenhouse or frame till required, but it is the best plan to transfer them to the open border at once if this can be done. In the case of poorly rooted specimens or of any choicer kinds that one does not feel disposed to leave to the mercy of the wintry weather in an exposed locality, it is a simple matter to protect them by means of frame-lights or temporary glass shades till they become established.

When planting do not leave the base of the plant in a cavity where the rain can collect and rot the stem. It is far

Digitized by Google

safer to raise the plant a little above soil level in damp situations. In such a season as this it will not be necessary to water the plants, but in a dry autumn this may be requisite for the first few weeks after planting out. The carnation will withstand drought better than most garden plants.

I now proceed to the all-important question of the choice of varieties, and in this and subsequent articles I will give a few particulars of up-to-date kinds that should appeal to all tastes and accommodate all pockets.

In this article I will confine myself to a very beautiful set of novelties raised by Mr. F. Payne, and which are being introduced by him this autumn. I have seen blooms of all the varieties mentioned, some of them on several occasions during the past flowering period, and I believe that this set is as strong a selection as any raiser has introduced during the past few years.

CRIMSON EMBLEM.—This is the most perfectly formed border carnation I have seen. If the petals had been trimmed with a pair of scissors, they could not be more cleanly cut. It is just sufficiently full to enable it to open without "balling" or splitting its calyx, and it gives blooms of large size. The stems are long and very strong. The colour is a deep velvety crimson and it is sweetly scented.

GLITTER.—The finest white self I have seen. It is a magnificent flower of fine build and huge size with a perfect calyx, and it possesses a strong clove scent. It has a glittering appearance when freshly cut and the name is an appropriate one.

PURPLE EMPEROR.—Like Glitter, this is another "giant," and flowers of 4½ins. and 5ins. in diameter can be obtained from disbudded plants. It is a rich violet-purple self. Mr. Payne tells me that it is a very strong grower.

DELIGHT.—An old rose self without any trace of colouring. It is a well shaped flower with strong calyx. This variety, which usually attains a height of 18ins., is said to be exceptionally free-flowering and of good constitution.

SPEEDWELL.—Old rose with a cerise centre. It is a large flower of fine form and has a good calyx. A strong grower and very tall, making it a good variety for planting at the back of the border.

SHOT SILK.—Salmon-rose, changing to a warm shade of old rose. Quite distinct in colour from Delight, and reminding one of an old rose silk dress. Strong, non-splitting calyx. I understand that this is a very strong grower.

NERISSA.—A very large white ground with a faint tinge of lemon yellow, heavily barred with old rose. This is a new colour break. It is a flower of fine form and has a good calyx, useful either for the border or exhibition.

GRACEFULNESS.—A flower of wonderful colouring, lemon yellow, lightly barred at the edges of the petals with pale purple and pale rose. On the yellow ground these look like flecks of pale bronze. This is a fine variety for growing under glass, when, with the calyx eased and helped occasionally, it can be grown to a very large size. Outside it bursts rather badly, but even then does not fall to pieces. If well grown it could be very beautiful.

FANCY CLOVE.—Pale yellow lightly barred and edged with rose pink. Very strongly clove scented. Fine form and good calyx. This is probably the only carnation in yellow to have any perfume.

ISOBEL.—A very dainty white ground fancy with delicate and clearly defined markings. Sometimes bursts, but not often. Good growth.

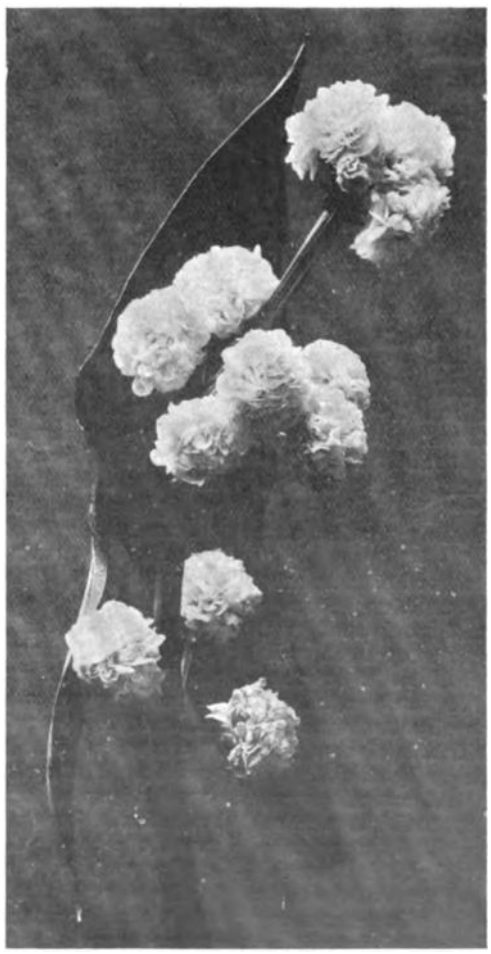
NORMAN LAMBERT.

(To be continued.)

THE WATER GARDEN

THERE are two classes of plants which can justly lay claim to be the most fascinating of all floral and foliage subjects — the mountain plants and water-loving plants. The gorgeous hues and chaste symmetry of the occupants of herbaceous borders make a loud and forcible appeal to the æsthetic senses, and command the admirations of the beholder; but the lovely dwarf mountain plant shares with its more humble, but larger-proportioned, waterside *confrère* the wondering respect and sympathy of all who trouble to take an interest in the garden.

Especially do we find something indefinably interesting in plants that haunt the waterside, or live and have their being in water. Although generally more "weedy" in appearance, the inflorescence of many of these plants is strikingly beautiful. Let the blossoms of the handsome arrowhead (saggitaria), the water lily (nymphæa), and spiræas be noted—and the glory of the water-flower is at once established in the mind. Consider the primula, with its many water-loving species (japonica, luteola, pulverulenta, sikkimensis) the bright-eyed forget-me-not, the little creeping-jenny, the yellow mimulus, the king cups, and our native primrose—and the beauty of the waterside plant asserts itself. Pressed into the service of the garden, these moisture-loving plants form a most valuable decorative asset, together with the many kinds of reeds, rushes, grasses and bamboos, that are now available from all parts of the world.

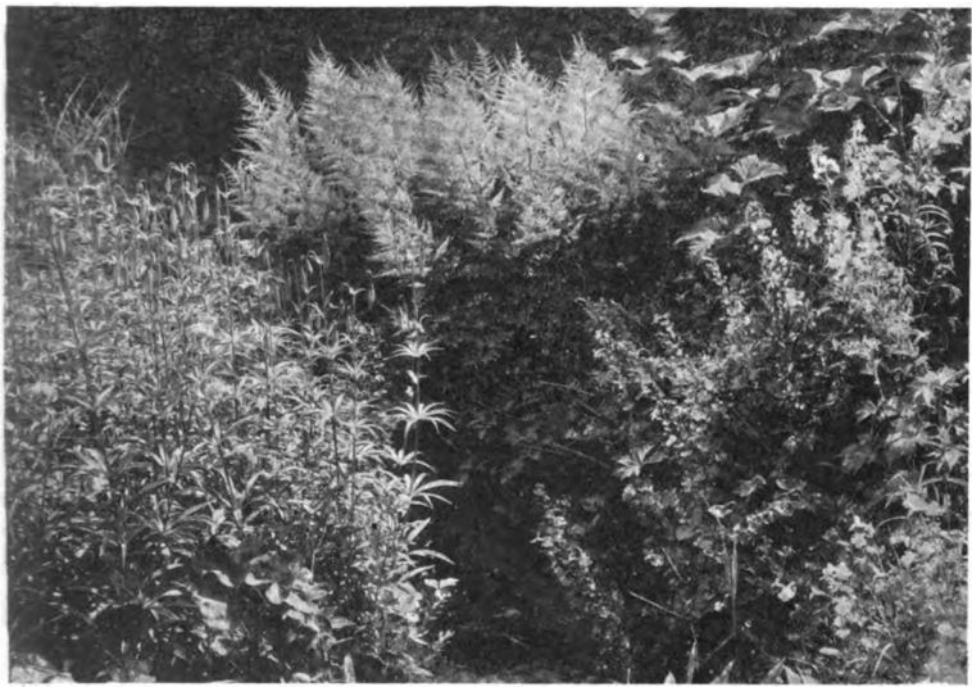


DOUBLE ARROWHEAD, A NAME DERIVED FROM THE SHAPE OF THE LEAVES.

Foliage plants in abundance can also enter into the water garden scheme, some of them being of huge proportions, as is instanced in the enormous leaves of the well known gunnera.

It is quite an easy matter to inaugurate and establish a water garden in the smallest of spaces, the scheme, of course, being commensurate with the area and convenience at command. One can even make a very attractive little water garden by collecting the native water plants that grow by and in our streams everywhere — wild spiræa (meadowsweet), caltha (king cups), cardamine ("lady's smock"), forget-me-nots, figwort, arrowheads, willow herbs, and numerous grasses and reeds; but the garden replicas of these plants are well worth the money they cost, and give greater satisfaction in the end. For the small water garden a few of the less rampant plants should be chosen, and, with a small pool (into which *one* basket of water lily

Digitized by Google



SUITABLE PLANTS FOR A BOG. ASTILBE CERES WITH LILIUM PARDALINUM IN THE FOREGROUND.

roots may be put) with a root of the beautiful arrowhead plant, fed from the household water supply (by arrangement with the water company), a charming water garden can be evolved.

The conduit which leads the water to the water garden can be made in the form of a channel running in any desired way that may be convenient; and its whole course will resolve itself into a charming trail of exquisite beauty, for on its banks can be grown a wide range of blossom and foliage suited to all times of the year.

One advantage of the water garden is the fact that its occupants are always fresh and vigorous in the hottest of weather, when borders and beds show every sign of exhaustion. There is no watering to be done, no anxiety for the safety of the plants in heavy rainfall, no labour in upkeep beyond preventing encroachment and overcrowding.

Larger spaces can accommodate more ambitious schemes. Many of the beautiful scenes shown in the photographs that illustrate this article can be created in the suburban or country garden of the average 50ft. by 200ft. size, the procedure following the line of planting a background of flowering shrubs and trees, with perhaps rockwork and rockery plants, and then constructing the pool and bog garden in the foreground.

It is not necessary to have a pool in the scheme. A conduit can be constructed to lead water to a depression, natural or artificial, in the garden. If this low ground is flooded with water, say, once a week, waterside plants can be grown with success; or a small trickle along the conduit will keep the whole water garden in moist condition. There may be naturally damp sites which could effectively be treated as a water or "bog" garden. In this ground plants which do not need actual contact with water will flourish amazingly. Suitable ones include the Japanese primula, our native primrose, Cardamine pratensis, forget-me-nots, mimulus, spiræas, certain kinds of lilies, bulbous plants, together with reeds, variegated grasses and bamboos. The whole of this garden may be carpeted with the brilliant yellow blossoms and pretty foliage of creeping-jenny.

A water garden is a thing of beauty and worthy of every consideration by all who possess a garden. H. A. DAY.

THE STORING OF HARDY FRUITS

THE essential conditions for the successful storing of fruit are not, perhaps, so much the place of storage as the condition of the fruit and the harvesting of the crop at the proper time.

The term "well ripened and finished" more often used to describe the condition of choice fruit such as grapes may well be considered in connection with the hardier kinds, such as apples and pears.

All grape growers know how much easier it is to keep a thoroughly ripened well finished bunch of grapes, to a late date for the variety, than one which lacks that quality.

In a lesser degree, but nevertheless an important one, is the condition of the fruit at the time of gathering, a governing factor in the successful storage of hardy fruit.

When making an analogy between the grapes and hardy fruit one has to remember that in the one the desired end is largely a matter of skilful cultivation under artificial conditions, whereas with the outdoor fruit uncontrolled conditions may, and often do, play a part in defeating that end.

The weather, so much blamed for half the troubles of mankind, certainly plays a big part in the proper development and finish of hardy fruits.

It is a matter discussed among fruit growers just now whether apples and pears will keep well this coming winter following a summer of heavy rainfall, low temperature and lack of sufficient sunshine.

In districts where the rainfall is normally low—averaging 23ins. or so a year—it has been my experience that fruit always keeps better after a wet season.

Though we have had that this year I am not confident of the fruit keeping well, owing to the lack of sunshine, a sufficiency of which is necessary for proper ripening.

Next to the condition of the fruit is the importance of gathering the crop at the proper time.

It is one of the wonders of vegetation that, providing a tree has not been overcropped and the fruit has not suffered any check in its development and finish, gathered at the ri ht time and stored properly, that it can be kept in perfect condition for months.

INTERIOR OF A FRUIT ROOM.

During this time a gradual change from the unripe, hard and often acid flavour is going on, to one of perfection for cooking or eating as dessert.

To attain this perfection of flavour and its maximum period of keeping, it cannot be too strongly emphasised that no fruit-room, however perfect, will counter-balance gathering at the wrong time.

At the time of writing (October 18th), most of the early varieties have been used. These remarks are therefore intended for mid-season and late varieties.

One is often asked by amateurs when are they to gather their apples and pears. The answer is that no definite time can or should be fixed for gathering. Much will depend upon the variety, the season, the soil in which the trees are growing and the position.

The main point is that late varieties of apples should be allowed to hang on the trees as long as possible. Our late varieties, such as Newton Wonder and Annie Elizabeth, will be gathered during the next three weeks.

Some people are tempted to gather too early; especially is this the case when from any cause a few of the fruits drop early. This may be due to damaged fruit, frequently by the caterpillar of the codlin moth, or occasionally by winds. Fruits damaged by this caterpillar will always fall in advance of perfect ones.

A simple test as to the fitness for gathering is to raise the fruit in the hand, when if it is fit for gathering it will part readily from the branch. If it requires a twist to remove it then it is not ready for picking.

Another test is to open a few fruits and examine the pips. If these are dark brown in colour, the fruit may be considered ready for harvesting.

When picking, the fruit should be handled with great care. Nothing in the nature of a damaged fruit, by either bruising, bird pecks, insect injuries or fungus attacked, should be placed with the sound fruit. All such damaged fruits should be used or disposed of as soon as possible after gathering and not stored, or, at any rate, kept entirely apart from the good ones. The receptacles used for gathering should have a little lining in the shape of paper, or wood-wool; this often prevents injury, especially to some of the softer-fleshed varieties.

Where much fruit is marketed it is frequently placed direct into wooden trays holding a bushel, or into bushel or half-bushel baskets, and stored in these until required for final packing for market.

STORAGE CONDITIONS FOR APPLES.

The storage conditions necessary for keeping apples are a cool steady temperature of about 35° to 40° Fahr. during winter, a slightly moist atmosphere, and partial or total darkness.

Various places are frequently assigned for the storage of apples. The illustration shows the interior of a well designed fruit-room, fitted with centre and side stages. It is so constructed that warm air is excluded and frost kept out. A building with a good thatched roof and sides is generally considered to answer these conditions better than any other made above ground.

So as to be able to prevent an ingress of cold or warm air, all fruit-rooms should be fitted with an inside and outside door. The space between the outer and inner doors can be so arranged as to leave room for office work of packing.

Ideal conditions of storing are, however, not always met with. Where apples have to be kept in a dwelling-house, the coolest room should be chosen, though safe, if possible, from frost. One of the worst places is the attic, but the cellar often provides an excellent one.

Apples are very liable to shrivel if kept in a room which is too dry. When such a room is the only one available, and only a moderate quantity of apples have to be dealt with, it will be found better to wrap each fruit in paper and pack them away in boxes.

Boxes holding a bushel may be used and after packing they can be stored

Digitized by Google

away in any suitable place. By such a method I have known Worcester Pearmain, a September to October apple, keep till January. For such a system of storing it is obvious that only perfectly sound fruits must be used.

Whatever room or building is used for storing, the fruit will require plenty of air for the first two weeks after being gathered. During this period they throw off a considerable amount of moisture, often termed "sweating." When this period of perspiration has passed much closer conditions will be necessary; in fact, very little air will be desirable at all.

If the fruits are arranged on the stages of a fruit-room—which, by the way, should have been thoroughly cleaned out and made sweet during the summer—it will be a good plan to place a very little clean wheat straw on the batten stages. This will prevent any from being bruised on the edges of the battens and will not prevent the little air necessary to pass through.

It is often advised that fruit should be spread out in single layers. This method certainly provides an easy means of examining the fruit, but it is by no means certain that it is always advisable. I do not object to seeing sound apples stored as many as four deep, and in a room inclined to be dry it is unquestionably better for the keeping of the fruit than the single layer system.

NAMING.

Although one may be personally familiar with the varieties, it is a good plan to label them as is shown in the illustration. It will be interesting to visitors if the season of use be added to the name. We also add to the label whether the variety is known to be self-sterile or self-fertile; also its origin if known.

The labelling, too, will be a reminder of the natural order of ripening of the variety and should be used in this way as far as possible, not only for prolonging the supply, but so that perfection of flavour is reached.

PEARS.

Pears require more care in storing and ripening than apples. The atmosphere should be dry and the temperature higher—from 40° to 45° Fahr.

The summer and autumn varieties should be gathered as ready and allowed to finish in the fruit-room.

Late pears should, generally speaking, be allowed to hang on the trees in the same way as apples and picked when the stalk will part readily from the branch.

Unless gathered, stored and ripened properly, the fruits are apt to become dry or decay in the centre, instead of becoming juicy and melting.

Most winter dessert pears will improve in flavour if brought into a warmer temperature for about two weeks to ripen. If allowed to ripen in too low a temperature they are often tough and poor in quality, instead of melting and buttery when ripened in a temperature of about 60° Fahr. During this final process of ripening the fruits should be placed in boxes and kept covered. If some sweet hay is used as a covering the colour is often improved.

ARTHUR J. COBB.

ORCHIDS AT VINCENT SQUARE

ON the occasion of the Fortnightly Show of the Royal Horticultural Society on October 21st nearly one-half of the Society's hall was occupied with orchids. Notwithstanding the past sunless summer, exceptionally fine results were in many cases achieved by the various exhibitors. Groups of outstanding merit were shown by Lieutenant-Colonel Sir George Holford, K.C.V.O., who won the Orchid Challenge Cup offered by Baron Bruno Schröder, as well as a silver-gilt Lindley Medal for the general excellence of cultivation. Gold medals were awarded to Messrs. Sanders, St. Albans, and to Messrs. J. and A. McBean. The Challenge Cup offered by members of the orchid trade was awarded to J. J. Joicey, Esq., Witley, Surrey.

LÆLIO-CATTLEYA QUEEN MARY VAR. COLOSSAL (C. Peetersii × L.-C. Lustre).—This plant carried two immense flowers of rich purple colour, the expansive and roundly formed labellum crimson-purple and prettily crisped at the margin. First-class certificate. Shown by Lieutenant-Colonel Sir George Holford, K.C.V.O.

LÆLIO-CATTLEYA QUEEN MARY WESTONBIRT VAR. (C. Peetersii × L.-C. Lustre).—This attractive hybrid bore a spike of three flowers of rich rosy mauve colour, with the large labellum of deeper tint. First-class certificate. Shown by Lieutenant-Colonel Sir George Holford, K.C.V.O.

AWARDS OF MERIT.

LÆLIO-CATTLEYA QUEEN MARY VAR. GLORIOSA (C. Peetersii × L.-C. Lustre).—A grand form with a spike of three flowers, in colour rich rosy mauve, the expansive labellum dark purple, tinged with crimson, and with a yellowish disc on each of the side lobes. From Lieutenant-Colonel Sir George Holford, K.C.V.O.

LÆLIO-CATTLEYA GOLDEN LIGHT, WESTONBIRT VAR. (L.-C. Golden Fleece × L.-C. luminosa aurea).—A vigorous plant with an erect spike of four large flowers, the segments rather narrow, but rendered attractive by their bright golden yellow colour, the labellum tinged with crimson on the side lobes. From Lieutenant-Colonel Sir George Holford, K.C.V.O.

LÆLIO-CATTLEYA LINDA SUPERBA (C. Dowiana aurea × L.-C. Arachne).—Flowers of large size and of an uncommon bronze purple colour, due to the influence of L. tenebrosa derived through the latter parent. From J. J. Joicey, Esq., Witley, Surrey.

CATTLEYA CLIVE VAR. ARDENTISSIMA (Adula × Iris).—Although but one flower was carried by this plant, the colour was particularly good, the broad sepals and petals of mahogany red colour, the widely expanded labellum deep purple. From Messrs. Sanders, St. Albans.

ODONTONIA STELPÆ (Miltonia Bleuana × Odontoglossum Harwoodii).—An interesting hybrid bearing large flowers, the rather narrow segments of yellow colour spotted with red-brown. From H. T. Pitt, Esq., Stamford Hill, N.

BRASSO-LÆLIO-CATTLEYA ALFRED MOLLET VAR. VIVID (B.-L.-C. Morna × C. Hardyana).—A showy hybrid with rich purplish sepals and petals and deep purple labellum. From H. T. Pitt, Esq., Stamford Hill, N.

CATTLEYA PYRAMUS VAR. CALOSSUS (L.-C. St. Gothard × C. Thurgoodiana).—A pleasing combination of the well known characters of both parents, the flower being well formed and of attractive coloration.

LÆLIO-CATTLEYA NANON VAR. ZEBRA (L.-C. Ivanhoe × C. aurea).—A remarkable form in which the spike of three large flowers had the petals almost covered with a bright purplish suffusion, thus resembling the labellum in this respect, but with a rose-tinted area around the margin. This singular

THE RICH BLOOMS OF LÆLIO CATTLEYA QUEEN MARY VAR. GLORIOSA.

Digitized by Google

character is believed to be constant in the above plant. From J. J. Bolton, Esq., Claygate, Surrey.

ODONTOGLOSSUM MAJESTICUM VAR. ADMIRATION (eximium × percultum).—Considering the unseasonable period of the year, this plant bore finely developed flowers of thick texture, the segments heavily blotched with crimson-purple, and with distinct lighter area in the centre of each petal. From Messrs. J. and A. McBean.

Evergreen foliage and the bright-coloured berries undoubtedly brighten one's outlook on life, especially if the day be murky and wet outside. The Aldenham House exhibit of evergreen and berried shrubs most certainly did cheer the visitor on his entry to the hall, and our congratulations are offered to the Hon. Vicary Gibbs and his head-gardener, Mr. Edwin Beckett, on their excellent collection of shrubs. The collection was truly an admirable one, there being representatives from almost all over the world, notably from China. The results and fruits of the labour of the various collectors in that part of the world are seen to advantage. The family of berberis was particularly well to the fore, and we should think that Aldenham has probably the finest private collection of species in this genus in the country.

A few of the more outstanding species exhibited were B. aggregata Prattii, B. dictophylla albicans, B. paniculata, B. orthrobotrys, B. Staphiana, B. Wilsonæ, B. bracypoda Gibbsii, B. intermedia with yellow berries.

In pleasing association with berberis were numerous species and varieties of cotoneaster from the cool temperate regions of the "Roof of the World." For beauty of fruit, grace of habit, robust constitution and easy cultivation, there is no group of shrubs which surpasses this genus. Notable species and varieties on view were C. frigida Vicarii, C. amœna, C. salicifolia rugosa, C. divarica, C. horizontalis perpusilla, C. Dielsiana, C. Semosii. Their close allies, the thorns (cratægus) were also in attendance, one of note being C. Crus-galli splendens with its masses of large, brilliantly coloured fruits. Pyrus, were also well represented, a splendid species being P. firma, literally covered with berries, and P. Malus baccata (variety). No collection of shrubs would be complete without the viburnums, the pyracanthas, phytolaccas and acanthopanax, with their fruits in reds, purples and blacks respectively. These were all included and lent a distinction, tone and effect to the whole stand, relieving the reds of the berberises and cotoneasters. Altogether it was one of the most magnificent collections we have ever seen.

The name of Messrs. George Bunyard and Co., Maidstone, is already so well known throughout the whole of the horticultural world in connection with fruit and fruit trees that it is scarcely necessary for us to draw the attention of our readers to their excellent exhibit on Tuesday last. This firm has contributed a great deal in the raising of this particular branch of horticulture to the high pinnacle which it has now attained, both from a scientific and also from a strictly utilitarian point of view. Fruit growing during the last twenty years and more has undoubtedly become, from the commercial aspect, a highly skilled science, and it is well known how successful Messrs. Bunyard have been in that line.

It is, indeed, a true saying that "Old friends are best," and Messrs. Bunyard, judging by their exhibit, evidently think along these lines. In the apples, such varieties as Newton Wonder, Emperor Alexander, Cellini Pippin, Sanspareil, Gascoyne's Scarlet, Magnum Bonum, Cutler Grieve, Charles Ross, were to the fore.

As is the case with the apples, the same holds good when one talks of pears. Such old varieties as Pitmaston Duchess, raised about 1865, and Doyenne du Comice, raised about 1858, are still well to the fore and can scarcely be surpassed for exhibition and dessert purposes.

CHRYSANTHEMUM MISS DOROTHY WILSON, OF PERFECT FORM AND GOOD COLOUR.

It is, indeed, a good sign that fruit growers such as Messrs. Bunyard recognise that these old varieties still deserve a place on the show table, and both the public and the grower will no doubt benefit in the end by their continued exhibition.

We congratulate Messrs. Bunyard on their well arranged table of fruits which were all in excellent condition and shown to advantage. It is earnestly to be hoped that with the new slogan of "Eat more fruit" and the old adage of "An apple a day keeps the doctor away," the public will realise the excellent work which our British fruit firms are doing towards assisting the human race to a healthier, happier life.

An excellent exhibit of vegetables of great variety was splendidly staged by Messrs. Sutton and Sons. It was considered by one of their own representatives to be the best exhibit they had ever shown. Everything on the stand was grown at Messrs. Sutton's trial ground near Reading, and most interesting because the varieties selected were all suitable for utility purposes. The quality was of a very high standard, but particularly noticeable were the fine size and variety of onions and capsicums, the leek Acquisition, and the various yellow tomatoes. The popularity of the latter is increasing rapidly, one of the best varieties being Sutton's Sunbeam, having an attractive oval fruit of delicious flavour. This firm in the past has staged such excellent exhibits that one would imagine that improvement was impossible, yet on this occasion, they have exceeded even their own previous best.

Messrs. Barr and Sons exhibited a most pleasing display of nerines of every shade, ranging from dark red, vivid crimson, scarlet, salmon, pink, and blush to white. Most striking of all was the variety Herda, a brilliant rose-pink with a deeper rose stripe down the centre of the petals. It was almost twice the size of an average nerine, attaining a height of 3½ft. and blooming well every year. Barcarolle, a beautiful rosy pink with a silver sheen; and Elwes' Seedling, a brilliant orange scarlet, were two out of the large number of excellent specimens. This display of nerines should help to popularise this flower, which is so useful during the autumn and winter months. They are easy of cultivation and Messrs. Barr's attractive varieties show their use as indoor decorative plants.

Messrs. Keith Luxford had an excellent stand of Chrysanthemums; although there were few novelties, yet the standard was exceedingly high. If any criticism could be made it was that a few were verging on the artificial in appearance, but that is a matter of personal taste. The size and form of their single chrysanthemums were exceptionally good. Estelle, a clear bright yellow, being most noticeable. Among the doubles a very effective variety for decorative purposes was Banquet Rose. Armorel, a coppery bronze, and Blanche du Poition, a pure white, should be included in all collections.

The following firms also exhibited:

Carnations. — Allwood Brothers; C. Englemann; and Stuart Low and Co.

Chrysanthemums.—W. Yandell.

Dahlias.—J. Cheal and Sons, Limited; James B. Riding; and J. T. West.

Fruit.—J. C. Allgrove; and G. Trinder.

Hardy Plants.—Bakers, Limited; S. Bide; Chalk Hill Nurseries; J. Cheal and Sons, Limited; William Cutbush; R. and G. Cuthbert; I. House and Son; B. Ladhams, Limited; Maytham Gardens; Reamsbottom and Co.; G. Reuthe; Rich and Co.; L. R. Russell; W. Wells, jun.; and Fred G. Wood.

Landscape.—K. and E. Hopkins.

Roses.—S. Bide; Elisha J. Hicks; J. H. Pemberton; and George Prince.

Topiary.—John Klinkert.

Violets.—J. Kettle.

NEW AND RARE PLANTS.

BERBERIS PRUINOSA.—This was shown in the form of two or three fruiting sprays, which had probably come from a shrub of about 6ft. high. It had the usual characters of the family, with the long oval leaves three to five together in tufts. The leaves are smooth

Digitized by Google

and leathery. Fruits are blue-black, which shows up an abundant plum-coloured or greyish bloom. It is an old species, having been introduced from Yunnan to France by Abbé Delavay in 1894 and this country three years later. It is a shrub which amply repays careful cultivation. Award of merit. Shown by Director, R.H.S. Gardens, Wisley.

PYRUS ALNIFOLIA.—Beautiful fruiting sprays of this hardy tree were much admired. It is a deciduous tree which in its native haunts of Japan and China reaches a height of 40ft. or 50ft. It is a very neat member of the Micromeles group. The plant bears fine crops of fruits which become brightly coloured and hang on the tree for a long period. They are one third to half an inch in length. It was introduced into cultivation about 1892. Award of merit. Shown by the Director, Royal Botanic Gardens, Kew.

P. ZAHLBRUCKNERI.—Another representative of this group from China, with beautiful fruits. Like its predecessor it is a deciduous tree. It is of comparatively recent introduction to these shores. The fruits are of a bright red in colour and oval in shape, about ½in. broad. Award of merit. Shown by the Director, Royal Botanic Gardens, Kew.

NERINE MRS. ARTHUR ELWES.—Flowers of this variety are of a fair size and of good substance—a satiny pink in shade. They are borne in large, bold umbels on tall stems about 1ft. to 1½ft. high, arising from the basal foliage. Award of merit. Shown by Colonel Elwes, Colesborne.

NERINE MISS E. CATOR.—Flowers of a good size and of fine form. In colour they are of a shade of rose carmine with a darker stripe on the petals. These are borne in large umbels on stems of about 1ft. to 1½ft. long. Award of merit. Shown by Colonel Elwes.

CARNATION WINSOME WHARTON.—Finely-scented flowers with a pinkish ground speckled with rose, borne on stiff, wiry stems and showed a good habit. Award of merit. Shown by T. R. Bentley, Skelton Castle Gardens, Yorks.

C. VISCOUNTESS HAMBLEDON.—The colour of this variety was somewhat unusual, not to our minds very attractive. The ground was a shade of apricot red. It was, however, lacking in fragrance. It was of good habit, the flower being carried well on stiff stems. Award of merit. Shown by Viscount Hambledon, Greenland, Henley-on-Thames.

ROSE PHYLLIS BIDE.—A beautiful, delicate, climbing, perpetual flowering polyantha variety of a pleasing pink colour on a yellow ground. Of its merit there can be no doubt owing to the many previous awards it has already received. Award of merit. Shown by Messrs. Bide and Son, Limited, Farnham.

CHRYSANTHEMUM THE WIZARD.—Large flowers of a shade of dark reddish brown—almost indefinable. The florets are stiff, standing out from the centre of the flower, which is of good shape. Award of merit. Shown by Messrs. Cragg, Harrison and Cragg, Heston.

C. GLORIOSA.—A large-flowered Japanese variety of a bronze to yellow in colour. Award of merit. Shown by H. Shoesmith, Guildford.

C. ENID ELDER.—The blooms of this variety were rather outstanding, being deep golden yellow in colour. It is a fine decorative. Award of merit. Shown by Messrs. Cragg, Harrison and Cragg, Heston.

SINGLE C. WHITE MODEL.—Well formed and fairly large blooms of almost a milk-white colour. The eye is a yellow colour. It is rather an improvement on Mensa. Award of merit. Shown by Mr. G. Carpenter, Byfleet.

SINGLE C. LADDIE.—Large blooms made up of six broad florets of a pleasant shade of soft yellow. The blooms were of good shape and the plants showed a fine habit. Award of merit. Shown by Mr. G. Carpenter, Byfleet.

C. MISS DOROTHY WILSON.—Fine large blooms of medium size in fine flower, made up of numerous overlapping and incurved florets. The blooms are of a good rich glowing yellow in colour and measure 4ins. across. It should prove a useful variety for all decorative purposes. Award of merit. Shown by Mr. W. Roots, Cranford.

C. JEAN PATTISON.—A splendid decorative variety which should prove popular owing to the attractive shade of coppery bronze. Award of merit. Shown by Messrs. Cragg, Harrison and Cragg, Heston.

JAPANESE C. SULPHUR QUEEN.—Very large flowers made up of long incurved soft yellow florets. The blooms were of great depth, probably about 9ins., and about 5ins. in diameter. They were borne on shiny, erect stems. Award of merit. Shown by Messrs. Keith Luxford, Harlow.

NEW CHRYSANTHEMUMS.

THE subjoined awards were made to new varieties by the Floral Committee of the National Chrysanthemum Society on October 20th:

C. FOX WILSON.—This is a medium-sized single chrysanthemum made up of substantial florets of orange-amber colouring. First-class certificate. Shown by Mr. G. Carpenter.

JULIA.—A very lovely exhibition Japanese variety of large size. The broad flattish florets droop elegantly, making a more graceful bloom than is often the case with the varieties which have broad florets. The delightful colouring is very elusive and difficult to describe. We believe the committee has registered it as rosy-bronze, but our colour impression is golden amethyst, for the ground colour is pale gold and this is freely stippled with purplish amethyst. The amethyst shading is not developed on the central florets, which are coloured pale golden yellow. First-class certificate. Shown by Messrs. Keith Luxford and Co.

LADY SAUNDERS.—Although this single chrysanthemum did not find favour with the Committee, we thought it to be very desirable. It is quite a large flower, but of perfect shape and made up of plenty of long narrow stiff florets of rich yellow colour. The disc is small and the flowers appear to have long-lasting qualities. Shown by Messrs. Keith Luxford and Co.

MISS DOROTHY WILSON.—This is a perfectly formed incurved variety of medium size which would be very valuable for decorative purposes. The colour is a rich, glowing yellow. First-class certificate. Shown by Mr. W. Roots.

WHITE MODEL.—Briefly this single chrysanthemum might be described as being an improved and earlier Mensa. It is a well formed and larger bloom than Mensa, relatively smaller in the "eye," and of milk-white colour. First-class certificate. Shown by Mr. G. Carpenter.

CORRESPONDENCE

ORCHIS HIRCINA ON WYE DOWNS.

SIR,—I am enclosing a life-size photograph of Orchis hircina, which I thought perhaps your readers might like to see, as there have been one or two articles in THE GARDEN recently with photographs which did not give a very clear idea of the flower.

The plant in question I found on Wye Downs, near Canterbury—a famous hunting ground for orchids—this summer. It is a very rare plant in the neighbourhood, and I believe it has not been found for several years, and then never more than a single specimen at a time. Other orchids found at the same time were: Orchis ustulata, O. Morio, Ophrys myodes, O. apifera, O. aranifera, Aceras anthropophora, Cephalanthera ensifolia, Orchis pyramidalis, O. maculata Listera ovata, Epipactis latifolia, Orchis fusca and O. f. alba, and Habenaria bifolia, the sweet-scented "butterfly orchis."—H. STEWART WACHER, *Canterbury*.

THE LIZARD ORCHIS.

THE PURPOSE OF WISLEY.

SIR,—To Mr. Laurence Cook I reply, "*Touché, mon vieux!*" To you, Sir, I offer my sincere thanks and congratulations for and on your able leader which deals quite effectively with our bone of contention. I neither withdraw nor apologise for my statement about catalogues, but let me say that my sympathies are entirely on the side of the nurseryman, among whom I am proud to count many friends and, I hope, no enemies. I quite understand and fully appreciate their difficulties, and my lance is couched, not at them, but at the two great societies, the R.H.S. and the N.R.S., whom I blame for laying the nurserymen open to the possibility of having inaccuracies in their catalogues.

Now, dealing with roses, as the leader has made quite clear, in Part B, Sections 3, 4 and 5, but particularly in Section 4, the indiscriminate hybridising and naming of hybrids (and of sports) and, may I add, the introduction of these to catalogues and the public, carried on by nurserymen and amateurs, have also given rise to new varieties, so-called, which are in many cases nothing more than variety differences, often not fixed, which revert to the type of the parent or one of them, but, having been tied to a new name, bear that name for ever and ever, because they have been christened so, and their owners, nurserymen or amateurs cannot bear to part with the new treasure. I am really sorry for Mr. Cook that he so sadly missed the point of my letter, and that he thinks I blame the nurseryman. I do not.

The N.R.S. in its "Catalogue of Ros[es]" has a list of roses too much alike which n[ot] not be shown in the same box as sepa[rate]

Digitized by Google

varieties. I assert that this list requires thorough overhauling, and some two or three hundred roses which have been shown in recent years should be carefully examined with a view to exclusion from or addition to this list. Moreover, I consider that a new list of decorative roses should also be prepared of the same nature and with the same proviso as to exhibition on the same stand. In both cases a yearly revision of these lists should also be undertaken. I am convinced that measures of this nature would do much to prevent incidents like the following examples :

In a local show I saw in a class for twelve blooms distinct varieties, two excellent blooms of Lord Charlemont in the same box, one correctly labelled, the other labelled "Victory."

Another case was that of an amateur who was showing in a class for six blooms of one variety. His variety of selection was Frau Karl Druschki, of which he had three blooms out of the six, two were examples of Louise Crette, and the sixth was a magnificent bloom of Candeur Lyonnaise. It was silver-medalled, and the box was awarded first prize in the class.

These examples afford illustrations of the truth of the recent leader, and of the urgent need for remedies at the hand of the N.R.S. The R.H.S., on the other hand, could with justice sweep the Augean stables of less intricate families, such as the primulas, campanulas, saxifrages, sedums. And, indeed, such a work would be well within its province. Is it not laid down within the objects of the Society ?

I hope Mr. Cook will tuck in his ruffled shirt within a tightened belt, and become in future one of the friends whom I have made among his brethren.—P. ARTHUR HENDLEY.

LILIUM AURATUM.

SIR,—The enclosed photograph is of Lilium auratum, or golden-rayed lily of Japan, as grown by me out of doors here, and represents what I think is a record. The plant

A WELL-FLOWERED SPECIMEN OF LILIUM AURATUM.

stood 6ft. 6ins. high and had twenty-seven flowers on one stem, all out at the same time. The bulbs were sent me by friends in Japan. I have grown these lilies for many years but have never seen one with anywhere near this number of blooms on one stem before. I am sure that this will prove of interest to the many readers of THE GARDEN.—G. DELL CLARKE, *Bournemouth*.

LABELS AND LABELLING.

SIR,—The reminder on the value of labels on page 692 is very opportune, as it comes at a time of the year when one may make amends, and so have the chance of avoiding disaster when there is little else to indicate the whereabouts of certain plants in the garden. I wonder how many, in the absence of a label of any sort, have thrust fork or spade into a border, only to realise, when too late, that some choice clump of lilies, or equally valued herbaceous plants like peonies, had been disturbed, if not ruined ? Autumn is a good season for renewing labels, while things are in one's memory and so avoid disaster. I care not what sort of a label it is, so long as it is visible and plainly indicates the plant. Herbaceous plants above everything else, ought to be clearly located as it is the easiest thing in the world, in a moment of forgetfulness to injure them when "straightening up at the back end." But there is another aspect of labelling although it may not be on a par with the tallying of plants, I refer to the naming of exhibits at shows. Towards the end of August I attended a provincial show at which some very creditable stuff was staged but, in my judgment, the exhibition from an educational point of view was shorn of its value as more than one half of the exhibits were unnamed. On referring to the schedule I found that the naming of exhibits was not stipulated. Surely a great omission, as I heard several visitors expressing disappointment at this, and were "guessing" at the sorts of potatoes shown. There were many plates of these staged, yet not one bore anything to indicate the variety.

Roses, too, and gladioli and apples left people in a bewildered state, as to "what was what." In framing schedules I would make it a condition that everything staged must be named. It is unfair to judges, and is disappointing to those who attend exhibitions to gain information.—W. LINDERS LEA.

SIR,—I am interested in your article on labels and labelling, as I use celluloid labels and have found them superior to any other kind. I usually number the labels and keep an index of numbers and names. In the case of plants given to me I have had your help for names and then labelled the plant, but usually I label the plants when I buy them. I find it quite impossible to remember all the names, and agree entirely with your article that labelling is necessary.—BURTON-ON-TRENT.

CAMPANULA CÆSPITOSA.

SIR,—I can well understand the difficulty that L. J. Rogers (page 688) has in procuring Campanula cæspitosa by name in catalogues. It was originally named C. cæspitosa by the botanist Scopoli. When first introduced to this country or about that time, it was figured by Curtis in the *Botanical Magazine* under the name of C. pumila. During the eighties of the last century it was the most popular small campanula in Britain, north and south, and was accompanied by C. pumila alba. Both of these were easy to recognise in the form of a patch on the rockery, for they formed a dense covering of a light green colour hiding the soil, the heart-shaped leaves rising on the stems to about half their height, which was 4ins. to 6ins. Now C. pusilla and its varieties are the most popular small campanulas in the country, and usually correctly named ; but occasionally labelled C. pumila, the synonym of C. cæspitosa. This bellflower creeps more widely than C. cæspitosa and its leaves do not cover the ground, but leave open spaces between the stems that arise from the creeping underground ones. C. cæspitosa is not extinct, for I see it occasionally under a wrong name, or no name at all. In old gardens it may be more common than it is generally supposed to be. I note that C. cæspitosa is catalogued by Messrs. Tucker and Sons, Oxford, and L. J. Rogers might find the right plant there. —J. F.

TRITOMA TUCKII.

SIR,—I enclose a photograph of Tritoma Tuckii, which may interest readers of THE GARDEN. I have not noticed three flowers on a stalk before, and I am sure many of the readers will find it a novelty. I am indebted to THE GARDEN for the help it has given me.—T. A. D., *Burton-on-Trent*.

A PECULIAR TRITOMA.

RHODODENDRON NOBLEANUM TYPE.

SIR,—I have often tried to cross this plant without success and have never seen a seed-pod on it, hand-fertilised or otherwise, so I considered it sterile. This year I see one plant here has set seed naturally. I shall be very interested to hear the experience of others as to whether they have noticed it seeding naturally or to any special pollen.—P. D. W., *Cornwall*.

DELPHINIUMS.

SIR,—I suppose that every named variety of delphinium has made a strong appeal to someone at some time or other, or it would never have been named. It is not given to any one person to know them all—certainly not all growing in different soils and situations—and even if it were there would still enter the factor of individual taste. Even so, too much can be made of individual taste, for there are many varieties of outstanding merit which appeal to the majority of delphinium enthusiasts. One has to live with plants really to know them, and, as one who has lived with delphiniums, I should like to supplement the list of varieties given at the end of the excellent article on page 643. It is a good list, better than one usually gets, but there are several important varieties left out. One of them is Blue Bird, second only, perhaps, to Millicent Blackmore in popularity. It is an intense deep blue of good form and medium size, and it is one of the earliest to bloom. Another very popular variety is Nora Ferguson, surely one of the best light delphiniums we have. This is closely followed by another gem among the lighter shades—Lovely—which personally I think even prettier than the last. In a small collection, however, both need not be included, as they are somewhat similar in character. Other excellent varieties not included in the list in question are Elsa, Ladye Fayre, Star of Langport, Lorenzo di Medici, Splendour and Corry—this last is excellent for so inexpensive a sort. The outstanding omission from the list in the Belladonna section is Persimmon, thought by many to be the best of its type. I should certainly have omitted Robert Cox from the list on page 644 ; it is somewhat mildew-resistant, but Pannonia is more so and is a much prettier variety.—THOMAS BONES, Jun., *Herts*.

SIMPLE GARDENING

CLEANING THE LEAVES OF PLANTS.

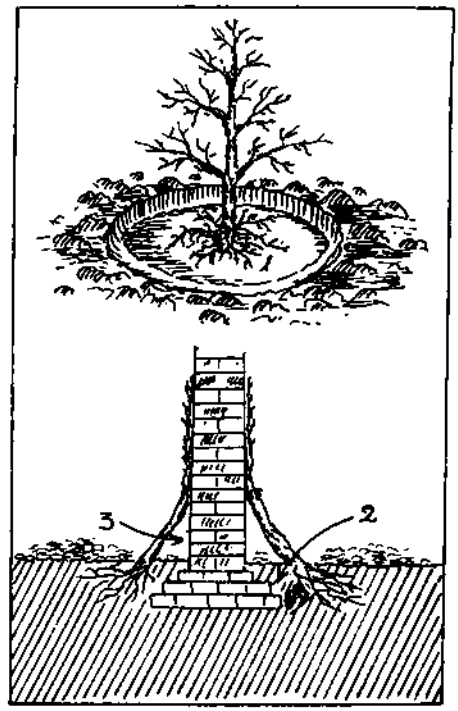
I AM now referring to the leaves of plants grown chiefly in windows, greenhouses and conservatories. Those plants that are infested with scale, mealy bug and white fly should be treated with insecticides sold by firms advertising in THE GARDEN, as home-made emulsions are not very effective applied against these pests. But red spider, black and green aphides can be dealt with in a very simple way. Furthermore, there are fine-leaved plants that become soiled through being subjected to the excreta from the aphides, and these leaves must be cleaned. Much foliage has matured now and will bear sponging and application of insecticides without injury—if the latter is carefully used—and better than during the growing period when the leaves are young. Place 2 oz. of soft soap in a quart of water and gently boil for ten minutes, then add a tablespoonful of sulphur and boil for ten minutes longer. Keep the mixture corked in a jar or bottle and use a wineglassful to a quart of rain-water for general sponging purposes. Always draw the sponge upwards on each leaf away from the stem and syringe with clean water after the sponging. Care should be taken to avoid injury to young buds, especially flower buds, to keep the liquid from them and confine the sponging to the leaves. If the sun is shining, shade the plants till the leaves are dry again, and prevent the emulsion reaching the soil in the pots.

THE TREATMENT OF HEAVY SOILS.

One of the most important of the items now claiming attention is that of digging or trenching heavy or retentive soils. If such ground is in a fit state, not waterlogged, the work of digging or trenching, if possible, should be carried on quickly, consistent with the doing of the work thoroughly. Later, when, perhaps, we have sleet or snow showers and more heavy rains, such digging or trenching will do more harm than good. If the newly dug soil is beaten down with rains, snow or sleet storms it becomes pasty and unkindly. The cultivator will find such soil, disturbed in the depth of winter, almost impossible to reduce to a powdery condition suitable for seeds in the spring. Only the top few inches will yield to the tools the lower soil being quite wet and mortar-like. This condition is bad for both seeds and young plants, and the trouble will remain throughout the summer months, newly turned lumps being too hard to break satisfactorily. So it is wiser to defer the digging of such soils till early in the spring if the work cannot be done, approximately, by the end of November. The subsoil should be well broken up but left below, and the top portion left in a lumpy state so that water will soak away quickly, air and frost follow and pulverise the whole to a considerable depth.

PLANTING FRUIT TREES.

This is very interesting work, because we see, in our mind's eye, the crops of handsome fruits that we expect to be available in due course and finer than any we have grown before. The soil should be well prepared before the trees are planted: it is directly to their benefit and to ours—especially in our own case—if the soil is freed of weeds. Allow ample



space for the trees to grow in; better be content with three if five would cause overcrowding. Bushes and pyramids of apples and pears on Paradise and quince stocks respectively should be planted 6ft. apart; plums and cherries 12ft. apart; currants, 5ft.; raspberries, in rows, 1ft.; loganberries, 10ft. These few examples will serve as a guide. Plant the same depth as when the trees were in the nursery; use fine soil round the roots, and do not unduly firm the covering soil at first, especially if it be rather moist. Drive in the stakes first, tie securely but in a way to permit of the tree settling down, and surface mulch. No. 1 shows the roots spread out; No. 2 shows how to plant near a wall to keep the roots clear of the foundation; and No. 3 shows the importance of leaving space between the stem and wall for the former to swell in in due time.

WATERING GREENHOUSE PLANTS.

Although there is more heat from hot-water pipes in the winter the soil in the flower-pots does not dry up as quickly as in the summer-time. In summer there is more evaporation and root-action is greater; more new leaves and stems grow, too. As there is less evaporation, less growth, both of root and branch in the winter, less water is required to maintain the plants in good health. If too much water is applied the plants become sickly, the leaves turn yellow and fall off. In the summer the spilling of water in the greenhouse or conservatory will not do harm—mostly it is beneficial; but not so in the depth of winter; then it chills the atmosphere, causing damping of the leaves and flowers, especially those of the zonal pelargoniums. Of course, in general, liquid manure and artificials should not be applied to plants during the winter months. Then there is the right time to water to be considered. I have found it best to use the watering-can between nine and ten o'clock in the forenoon.

RE POTTING ROSES.

Some varieties of roses grow and flower satisfactorily planted out in borders under glass. But there is not convenience for this in every structure, and the lover of early rose blooms resorts to pot culture. The planted out specimens do not require as much attention as those grown in pots. The latter should be re-potted or top-dressed every year, and the present is a suitable time for carrying out this work. Roses thrive best in a good stiff loam, but it must be mellowed by sufficient storing so that all grass roots in it are dead, otherwise trouble will follow the potting. The loam should be reduced to small lumps, preferably by hand, spread out on the floor or potting-bench, and to each bushel add a single handful of bone-meal and double the quantity of wood-ashes; mix the ingredients thoroughly. The larger pots should be clean and dry, also the crocks. When the plants are turned out of the pots carefully remove all loose soil found, without damaging the roots. Make sure that the drainage is good, then re-pot so that the old ball of soil is evenly surrounded by new compost. Make the latter firm with the potting stick and see that the top roots are nicely covered.

GEORGE GARNER.

MÈDOC and GUIENNE SÉCATEURS

AN ERROR CORRECTED

Mr. Jardine, in his Descriptive and Illustrated Price Lists, which have been distributed all over the world, upon the guarantee of his manufacturer's late deceased Agent, has continuously stated that the steel used in the blade and serpette of these sécateurs is the FINEST SHEFFIELD SHEAR STEEL. Upon test instigated by himself, it has been found that etching has shown no signs of shearing in the steel, and, therefore, this proves the incorrectness of these statements which Mr. Jardine most sincerely regrets. The steel in question is a fine quality Sheffield steel, but not shear steel, and with the French method of pickling is still the best steel put into sécateurs, as numbers of users all over the United Kingdom testify.

A VISIT TO CRAWLEY

A VERY pleasant afternoon was spent at the nursery of Messrs. J. Cheal and Sons, Limited, Crawley, a few days ago, despite the adverse weather conditions which attended the visit. This nursery has long been in the forefront of the horticultural trade with a high and well established reputation behind it. Under the present *régime* it has made marked progress, continuous extensions having been made until it has assumed large dimensions, to cope with increased trade. Not a square inch of the whole area is wasted, all available space being employed to the best advantage. What strikes one most is the exceedingly fine soil conditions which exist in that area. The fine results of these conditions are outwardly expressed by the remarkable growth and healthy appearance of all the many plants in the nursery. Everything seems to thrive, from conifers to dahlias. This fact reflects great credit on all who are responsible for the care and attention devoted to the plants. On entering the nursery the visitor is confronted with a veritable sea of all conceivable shades and tints of colour. Herein lies the fame of Messrs. Cheals. It is the trial ground for their dahlias. Singles, stars and collarettes are gathered together in one field, while another houses the large cactus-flowered varieties, along with the peony-flowered and decorative kinds, down to the miniature pompons. A collarette variety by the name of Amy Barillet probably has a great future in front of it. It is of a fine dark maroon colour with a dark eye. A very good contrast is obtained between the foliage and the flowers. The star dahlias, which are rapidly becoming popular since their introduction by Messrs. Cheals, were in the best condition, being wonderfully free flowering with the blooms borne well above the foliage on erect stems.

The varieties in the other classes are too numerous to mention by name, but all showed the results of careful cultivation and selection. It was noticeable that in the cactus-flowered section that the stems were becoming more stiff, holding and displaying the flowers well above the foliage. One had perforce to leave the dahlias behind and proceed to a very fine collection of trees, shrubs and fruit trees. Many good trees and shrubs, such as Prunus Pissardii nigra, were to be seen, all showing to the full the results of the very wet season we have experienced.

There was an excellent display of topiary work which generally holds a certain amount of interest for the visitor. The conifers were doing as well there as in their native habitat and one almost imagined when walking through that part that they were in a properly established forest nursery. The conditions and the general health of all the plants in the nursery deserve words of commendation, for without great trouble and labour these fine results are not readily attained.

HARDY BULBS FOR AMATEURS

A HAPPY inspiration surely prompted the compilation of this handy little volume ("Bulbs for Amateurs," by the Rev. Joseph Jacob. "Country Life," Ltd., 5s. net.); it fills a much felt want. So many of us desire to know something about the ordinary bulbs of the garden and how to grow them: which is the best blue hyacinth, what purple irises to grow, how deep to plant bulbs, when to take them up and the numerous questions that arise when one is beginning to grow bulbs in garden or woodland.

It is a compact little book, convenient in size, that one will need to have at one's elbow to turn to when points arise concerning the choice of bulbs and their proper treatment, what to grow and in what soil and situation to grow them.

It deals with the usual bulbs of the garden, giving cultural directions and offering advice in the selection of varieties, and instructions as to their growth and proper management.

It is written with the sympathetic knowledge of one who loves his bulbs and would help others to a fuller enjoyment than is usually experienced in the haphazard methods so frequently practised. Its intention is to attract the curious, awaken interest and stimulate the aspirations of all who would know more about the cultivation of their favourite flowers.

It is as a sign-post pointing the way the enthusiast should tread if he or she desires to enter the portals of floriculture and seek initiation into the esoteric cult of the hybridisers of iris, tulip or crocus or other of the numerous families of bulbs.

The author enumerates many hardy bulbs which he happily describes as being at "the gate" waiting to be beckoned into the garden; he tells of the hospitality they should receive and the quarters wherein they should be lodged.

If after having one's interest awakened in a flower one learns its habits and properties and seeks further knowledge and wishes to enjoy the serener pleasure of flower culture in raising seedlings of one's own and thus experiencing the joys of the unexpected, it is the purport of this book to deepen such interest and increase such desire. As an encouragement Mr. Jacob tells us some of the best varieties have been raised by beginners.

The road the florist wanders along is a pleasant path strewn with flowers all the way. "Hardy Bulbs for Amateurs" is a very readable book and well illustrated by photographs of groups of flowers in suitable situations; the frontispiece, "Daffodils in Grass," is a delight. C. W. N.

SHRUBS FOR AMATEURS

IN writing this little book ("Shrubs for Amateurs." "Country Life," Ltd., 5s. net.) Mr. Bean, Curator of the Royal Botanic Gardens, Kew, deserves the thanks of all those interested in shrubs, and epecially those who require advice in a concise form, in a volume of handy size on the selection and cultivation of shrubs.

The popularity of shrubs in our gardens has increased enormously during the last twenty years, and this is hardly a matter of surprise, when we consider their beauty of form and the floriferous character of many of the genera and species, both of the older as well as those of more recent introduction. The numbers of introductions during the last few years by collectors in the East as well as other parts of the globe have been so many that the task of selecting is sometimes a rather bewildering one to the maker of a garden. In "Shrubs for Amateurs," the author has endeavoured to put his life-long experience and unequalled knowledge at the service of the cultivator of shrubs in a concrete form to assist him in selecting and growing the plants he desires to the best advantage. The book is written in a clear and lucid style in language that may be easily followed by all, without the use of many botanical terms that to many might be confusing. Much information is given in the opening chapter on the cultivation of shrubs, with the best methods to adopt in improving a poor soil as well as the measures necessary to keep a suitable soil in a fertile state of cultivation. Lists of plants are given which not only contain the best of the older favourites but also many of those more recently brought under cultivation.

By a reference to these lists the intending planter can at a glance find those shrubs best qualified to suit the positions it is intended to plant, whether these positions have a sunny aspect, or a northern exposure. Lists will also be found for poor soils, and dry, sunny places. If the reader should wish to plant for coloured foliage effects, either by variegation, or autumn tints, good selections will be found suitable for this purpose. There is also a large list of shrubs of diminutive proportions suitable for the rock garden, both evergreen and deciduous. By a reference to other lists the time of flowering can be readily ascertained, and by a judicious selection the interest in the garden will be continuous for almost all the months of the year. In the chapter on propagation many useful hints are given on this interesting subject, and the experience of many years is concisely stated to enable the grower to perform this work of increasing his stock from seeds, cuttings, layers, or division, which the writer points out may be done in many instances without any very elaborate appliances. Good advice is also given in the chapter devoted to pruning, as well as arrangement, grouping and transplanting, which are all worth perusal and are instructive in these important branches of horticulture. Nearly one hundred pages are devoted to descriptions of shrubs. These are arranged in alphabetical order according to their genera. In this manner most of the plants of merit in our gardens are mentioned, and may easily be found under the heading of each genus, with their requirements regarding soil and situation, as well as the colours of their flowers and foliage and the sizes to which they may eventually be expected to attain.

Mr. Bean is to be congratulated in producing such a useful little book, which, though ostensibly written for the amateur, should be of considerable use to the professional gardener; indeed, it might well be in the hands of all who possess a garden, whether of the smallest villa type, to that of far more pretentious size and expectations. It is well illustrated with fifteen full page photographs of specimens isolated and in groups.—R. L. H.

OBITUARY.

MR. WILLIAM CHARLES BLAXILL.

WE regret to announce that Mr. William Charles Blaxill, for over fifty years in the service of Messrs. Sutton and Sons and for the past eleven years head of the firm's exhibition department, passed away at his residence in Tilehurst Road, Reading, on October 17th, aged sixty-seven.

Mr. Blaxhill joined the staff of the Royal Seed establishment in January, 1874. For the first few years he was in the invoice and ledger offices, but it was always manifest that his *forte* was in the direction of the outside rather than the inside work of the great seed business, and some few years ago he was appointed by Messrs. Sutton head of their exhibition department, where his skill and taste in the effective arrangements of the many wonderful exhibits he staged for the Reading firm were well known to visitors to the horticultural shows up and down the country.

EDITOR S TABLE.

MESSRS. BARR AND SONS have sent us a fine bunch of their excellent pink Michaelmas Daisy Barr's Pink, which received an award of merit in 1922. The colour is rose with the slightest touch of purple in it, but in no case could it be called a magenta. The shape of the flower is good and the habit graceful.

WE much regret that through an error Rose Vanity was mentioned in our issue of October 18, as having been raised by Messrs. A. J. and C. Allen. This fine rose actually originated in the nurseries of Mr. J. H. Pemberton —[ED.]

BORDER CARNATIONS

HOWEVER beautiful the new varieties a firm may send out (see article in this issue), there will be no satisfaction to the buyer unless the service be equally good. The following is an excerpt from a letter received on 17th October and is typical of the appreciations coming to us by every post at present :—

"The Carnations arrived safely and I am very pleased with them. I have bought from other growers this season, but your plants are the strongest, best rooted, best packed, best labelled, and what is more, the soil did not fall away from the roots when they were unpacked. I enclose a further order, and cheque to cover cost."

DESCRIPTIVE PRICE LIST ON APPLICATION.

APPLES & STILL MORE APPLES

THE GARDEN has always advocated the growth of more home fruit. So far it has been rather difficult to obtain definite statistics of the amount of fruit consumed in this country and grown outside of it. Here is some information which might interest our readers:

Messrs. Burnside and Co., a firm of Australian merchants, have been responsible for the display and sale of apples in the Australian pavilion at Wembley. Since the exhibition opened they have served over 1,000,000 customers by means of a staff of 120. Over 1,500 tons of apples have been sold. They have now ordered another 50,000 cases from Australia in order to cope with orders from visitors to the exhibition. These numbers are staggering. If we have to buy apples abroad, by all means let us buy them from the colonies; but why the necessity to buy fruit from overseas. Enough could be grown in the British Isles to satisfy home cousumption. There appears to be some hoodoo on English apples, and yet our readers might be interested to know that a well known fruit grower in Kent has built up a lucrative business in exporting English-grown apples to the Argentine, where they are in good demand.

They call this the greatest fruit country in the world, but the question of supply and demand presents some curious anomalies. Of course, the reason is fairly obvious: the commercial growers in the past have not troubled to grade apples and pears for the home market, nor have they bothered to pack them properly and so make them attractive. They are gradually waking up to the fact that proper grading and attractive packing help to sell fruit, but the buying public still has a great deal to learn, particularly that our fruit is the best in the world.

CERCIDIPHYLLUM JAPONICUM

WHILE visiting one of the great private arboretums noted for its autumn colouring I was lucky enough to see this plant at its best. Many readers of THE GARDEN will also remember the fine vases of it shown by Mr. Mark Fenwick at Vincent Square a week or two ago. In Japan it is often found over 100ft. in height, but the tallest tree in this country is about 40ft. The foliage is particularly neat in appearance, the leaves being heart-shaped, about 2ins. long and usually opposite. The value of the tree has been rather neglected by writers on trees and shrubs, for besides being graceful in habit at all times of the year, it colours fairly early in the year when most colours in the garden are dingy. There appear to be two distinct forms: one, which includes the earliest importations, turns almost a butter yellow, while the other, which may just be a sport, turns to a rich russet. I cannot express my opinion of this fine plant strongly enough, which is certainly one of the most valuable small trees that is in cultivation. It is obtainable from several nurserymen. Talking about different forms of a plant, there is a fine form of Rhus Cotinus, called atropurpurea, which has a purple tint to its foliage throughout the year. This is valuable, as Rhus Cotinus does not make a fine show of flower every year and in the north is rather a shy flowerer. This purplish form is an added attraction, and is obtainable in commerce.

SEA BUCKTHORN

THE orange berries of this seaside shrub have rarely been so plentiful as they are this year. Like the pernettya, it has male and female forms, and at least one male has to be planted to every six females in order to make it berry well. This lack of male plants is perhaps why the numerous bushes along the shore at North Berwick are such poor fruit bearers This plant is too well known to require description, but it is interesting to examine the small brownish star-like scales which cover the stems and branches. The fruit is so acrid that no bird will touch it until it is over-ripe and then only on occasion. In very cold weather magpies are known to frequent the bushes in search of food, but I know of no other bird with a digestion capable of assimilating such a bitter morsel. Although commonly known as a seaside plant, it will succeed equally well away from the sea, but it is perhaps a faddy subject with unknown likes and dislikes, it is, however, a most attractive plant and should be tried more often. Mr. Bean is particularly partial to this handsome shrub. He says of it: "Perhaps no other fruiting shrub is so attractive as this for so long a time." This is a fair judgment of its beauties, for the orange berries hang a long time and make a most pleasant contrast with the grey-green foliage. Where it finds itself at home, it sends up a plentiful supply of suckers. E. H. M. C.

SOME UNCOMMON SHRUBS

We are sometimes asked to give the names of shrubs which are not generally seen in the ordinary garden. This is a good sign, for change is often a good thing and a break away from ordinary shrubs makes the garden not only more interesting but also more attractive. In this article will be found short notes of several shrubs which are not well enough known and are worthy of being planted in every garden.

OF all the plants which Reginald Farrer introduced from China, Buddleia alternifolia has probably the greatest future before it. In fact, it is impossible to praise this invaluable plant too highly. It is a widely branched and extremely vigorous shrub, carrying masses of rich lilac blossom during June. This blossom is born on the previous year's growth, which makes it important to grow the plant in a sufficient area to allow it to expand. It is unlike most other buddleias in appearance, but its long arching branches, small foliage and delicately shaped flowers make it worthy of being grown in all gardens. It is perfectly hardy, will grow in any soil, and is exceedingly easily propagated from cuttings. It should not be grown in shade. With these obvious advantages B. alternifolia is a plant which will soon be seen in every garden.

Vaccinium parvifolium is another deciduous shrub which should be more often grown. It is the common red huckleberry of Western America. It grows to a height of 5ft. or 6ft., is slender of growth, with small foliage, which turns to a fine crimson in the autumn. The flowers are solitary in the leaf axils and are not particularly striking, but the fruit is scarlet, rather acid in flavour and excellent for jams or pies, being treated in the same way as cranberries. Although known for many years, for some reason or another this plant has not received sufficient attention in this country. It is quite hardy, can be grown either in the open or in moderate shade, but will not stand lime. A fairly moist situation with plenty of humus in the soil suits it best.

THE DEEP PINK BELLS OF ARCTOSTAPHYLOS MANZANITA, AN ATTRACTIVE EVERGREEN SHRUB FROM CALIFORNIA.

Arctostaphylos manzanita is an attractive evergreen shrub from California, where it becomes a small tree, although in this country it rarely exceeds 8ft. The leaves are heart-shaped and leathery. It flowers in April and the flowers have the advantage of lasting a long time. They are deep pink in colour and are borne in short terminal panicles. It does not fruit in this country. It is quite hardy as long as it is sheltered from the wind and will grow either as a wall plant or as a bush. It will strike easily from cuttings, but they must be taken off short and they are the better for a little bottom heat. Its stiff appearance and red branches are most attractive at all seasons of the year. It will not grow in lime, but any good loam satisfies it. There are two other members of this genus which are found wild in this country, A. alpina, the black bearberry found in the North of Scotland, and A. Uva-ursi, the red bearberry, which is fairly often seen in the wild state high up in the North of England and in Scotland.

Styrax Wilsoni.—Although this beautiful and distinct deciduous shrub is of comparatively recent introduction, having been brought by Wilson in 1908 to these shores from western China, it is one which has already made a wide appeal to all lovers of garden shrubs by reason of its striking beauty. Like the group to which it belongs, of which three or four species are in general cultivation in this country, it is a shrub which may assume a tree-like form, attaining from 6ft. to 10ft. in height. It is generally much branched and the young shoots are noticeable, being covered with a characteristic down. The green oval leaves are also covered with down when young. Its chief beauty, however, lies in the masses of pure white flowers which are produced during June. These are fairly large and along with the nodding habit on long stalks at the end of the lateral twigs they give an excellent effect. The shrub is remarkable for its early flowering as when it is only a few inches high and about three years old it produces many of these beautiful shining white flowers set off to advantage by the yellow staminal columns. Like the other species in the group it requires careful attention during its youth. It generally does best in a sheltered spot in the garden, being given a good sandy loam, to which has been added a small proportion of peat and leaf-mould. Once they become established they generally do well. This species is best raised from seed, although in the case of other species cuttings prove successful.

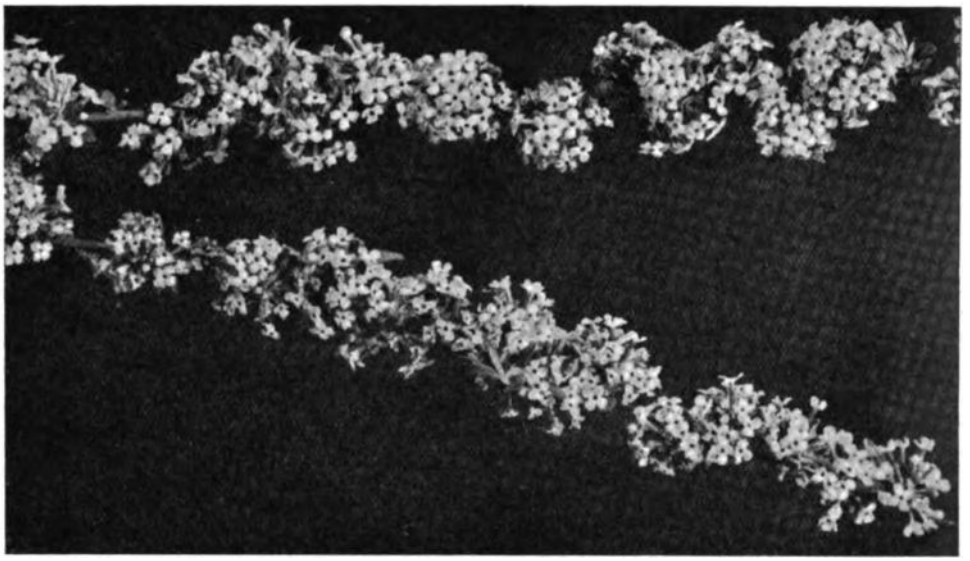
Osmanthus Delavayi is another shrub which has only been in cultivation in this country a comparatively short time, long enough, however, for its value to be recognised as a distinct acquisition to our already long list of flowering shrubs. It is a member of the same family as the lilac of our gardens and is also closely allied to the olive, having the same characteristic opposite stiff dark green leathery leaves. It is also an evergreen, which adds considerably to its value. In this country it reaches 5ft. to 6ft. in height with spreading and somewhat pendulous branches. The flowers are pure white and fragrant and are borne in axillary or terminal clusters. In that way it differs from other species in the genus. Like so many others of our newer shrubs it is an introduction from Yunnan and appears to be hardy in this country. It is slow-growing and seems to prefer a light loamy soil and, like styrax, a slightly sheltered position. With these requisites it thrives successfully and well repays the care and attention which should be devoted to it when young. It can be readily propagated by means of cuttings in July if these are put into a case with slight bottom heat. It is a handsome shrub with an almost holly appearance and is one which will certainly add an undoubted charm to the garden.

One of the commonest deciduous shrubs of the middle and south of the United States, which flourishes in the lowlands and on the hills, is the much admired flowering dog-wood, Cornus florida. In its native country it is of vigorous habit and grows from 10ft. to 20ft. in height. For many months in the year C. florida presents a most pleasing appearance, from springtime when it is covered with a profusion of white or rose coloured flowers, until the red tinged leaves and

Digitized by Google

quantities of red berries deck its branches in late autumn.

This mass of showy white blossom is really an involucre surrounding the small and insignificant flowers which are tightly packed together in a greenish yellow head, measuring ½in. across. The bracts are four in number, 2ins. long, white and somewhat heart-shaped, having a broad indented apex. They are formed in autumn, enclose the flower during winter, and expand gradually in spring. The dark green leaves are opposite, 3ins. to 6ins. long and 1½ins. to 3ins. wide, the underside of which is pale, glaucous and downy. The bracts of C. florida rubra are bright rosy red instead of white. C. florida is unharmed by the dry cold of America, but suffers considerably from the dampness of an English winter and the late spring frosts. In the warmer parts of England, planted in a situation where as far as possible it escapes these late frosts, the shrub thrives well, but rarely reaches a height greater than 10ft.



THE BEAUTIFUL LILAC AND ORANGE SPRAYS OF BUDDLEIA ALTERNIFOLIA.

Although it is nearly 200 years since C. florida was first introduced into Britain, it has never become generally cultivated. Such a beautiful shrub should not be overlooked.

Among the fifty species of viburnum which have been recorded from China is V. utile, a shrub of graceful habit and 4ft. to 5ft. in height. It was discovered near Ichang in 1880 and introduced into Britain by Wilson in 1901. It has proved to be quite hardy and to prefer limestone.

The long thin branches are covered with pale stellate down. The leaves are 1in. to 3ins. long, ½in. to 1in. wide, oblong in shape, leathery and glossy in texture above, white and prominently veined underneath. In May the minute white flowers are produced in a densely packed umbel about 3ins. across. Towards autumn attractive black berries which are dry and oblong, ornament the shrubs.

The feature of this viburnum is that the flowers are fertile, whereas in several species there are two distinct types of flowers, sterile and fertile, the sterile ones being larger and more showy, used to attract insects to the inflorescence.

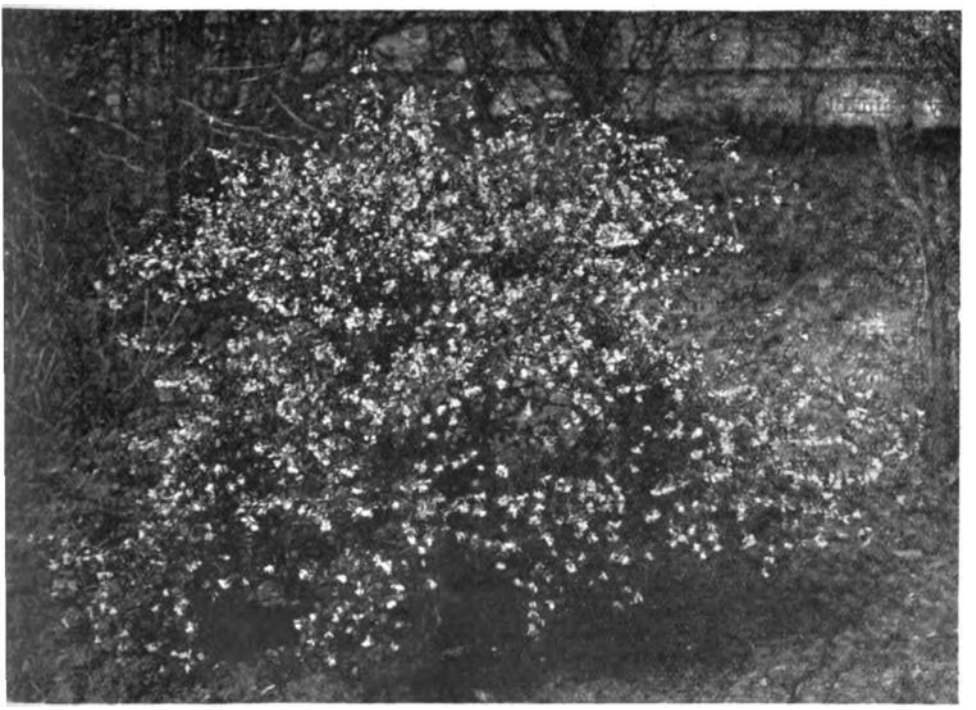
Planted in a border or at the edge of a shrubbery, V. utile is most valuable, being quite hardy, compact, and growing freely in any good loam. When it fruits in profusion it is one of the best of the viburnums in an autumn garden, but, unfortunately, it does not fruit freely every year.

Although Genista cinerea is one of the finest of its race and long known to a few gardens, it is still very uncommon. It seems to be equally rare in nurseries, for any efforts to obtain plants last season generally resulted in obtaining only poor specimens, evidently grown indoors, which would scarcely survive through the winter. Why G. cinerea should be out of favour one cannot guess. Lack of hardiness can scarcely be the explanation, since the Madeiran G. virgata, which is closely allied to it is absolutely reliable almost anywhere, and the former has done well at Kew for many years.

Of the many lowlier brooms suitable for the rock garden, the margins of heath slopes and the like, there are few early summer kinds to equal Genista tinctoria fl. pl. This is a quite dwarf, practically prostrate shrub which makes a large and dense leafy mat of bright green, just above which rise the short racemes of blossoms. These latter are a good, full yellow, richer than that of the type, and they are produced so abundantly that a well grown plant will be a blaze of gold. This accommodating little shrub will prosper in the driest and poorest soil, but it demands the fullest sun. In certain areas G. tinctoria fl. pl. comes into bloom just as that other valuable species, Cytisus decumbens, is going off.

Cytisus purpureus, with its varieties alba, incarnatus and others, is one of the most distinct of brooms when well grown, but too seldom does one get the pleasure of indulging in a vision of a really happy-looking specimen. It seems odd that this hardy European species should jib at life under conditions which are admirably suited to brooms generally. Mildew is frequently found to be one of its afflictions, and also slugs and snails. But these are secondary factors, since a really healthy shrub will rarely be attacked by such pests.

A distinct dwarf form of the yellow-flowered shrubby cinquefoil, Potentilla fruticosa, is well worth growing. This form was introduced by Farrer, and has distinctive value in its freedom of flowering from early summer to late autumn. This shrub produces especially charming effects in the rock garden if it is allowed to scramble over the stones.



OSMANTHUS DELAVAYI CLOTHED IN FRAGRANT WHITE BLOSSOM.

Digitized by Google

PROTECTING TENDER PLANTS DURING WINTER

MANY choice plants cultivated in various parts of the country are more or less half-hardy, and some timely and suitable protection makes all the difference to their coming safely through spells of frosty weather. Before dealing with protective methods and the material used, it will be well to consider a side of the question which is too often overlooked, but which in some ways is really more important—and that is the position and aspect in which tender plants are placed. Many cultivators with insufficient knowledge of this particular branch of horticulture imagine that tender plants should be placed in very sunny situations where they can get all the sunshine possible. This is, of course, a natural thing to do. But in practice it has proved to be wrong; for such plants, when frozen, if exposed too quickly to bright sunshine, which often follows a frosty night, usually suffer severely even if they are not killed outright. The damage is caused by their not being allowed time to thaw out gradually. The same plants if planted in a west, south-west or north exposure will probably be unharmed because they have time to thaw out gradually. Protection from the sun may be afforded by a wall, fences, belts of shrubs, or even individual trees and shrubs. This question of aspect is very important where woody plants are concerned. In dealing with tender bulbs or plants of a herbaceous character it is not so important, for they require all the possible sunshine in order to ripen them properly, and as they generally die down during the winter it is an easy matter to protect them with some dry material, such as a covering of ashes, evergreen branches or even glass lights. In using protecting material for tender plants we should regard it as a more or less necessary evil, and as far as possible no protecting material should be used until it is really necessary, and it should if possible be of such a character that it can be easily removed between spells of frosty weather. There is quite a wide choice of materials, but whatever is used should be as light as possible. It should also keep dry for the longest possible period and be of such a character that it allows a free circulation of air, as all material which lies close and wet and excludes air possibly does more harm than good. In some parts of the country it is necessary to protect roses, and it is an all too common practice to give them a heavy mulch of cold wet manure, which excludes air and in every way is unsuitable for the purpose. Dry strawy litter should be used; but possibly the best way is to draw several inches of soil up round the stem of the plant, or a handful of dry bracken may be twisted round the stem. In cold, exposed situations drying winds combined with frost often do much damage. In such positions sheltering hedges, fences or walls are of prime importance. Where such shelters do not exist much can be done by using wattled hurdles or hurdles thatched with various materials. They are very valuable for this purpose and make effective wind breaks, and may be used to enclose a piece of ground or shelter individual plants. They can also be placed over plants growing on low walls, leaning them up against the wall at a suitable angle; they can easily be secured against being blown down. Light frames covered with mats or canvas are very suitable for the same purpose. They can also be used to cover plants growing on walls that are exposed to bright sunshine early in the morning. By thus shading them they are allowed to thaw out more gradually. Loose mats and canvas sheets may also be used for placing over plants growing on walls, as well as on frame-works erected over tender plants in the open. Woody plants with bare, exposed stems are often susceptible to injury from frost. Such stems may be permanently protected for the winter by wrapping them round with haybands.

Shrubs with short, bare stems may be protected by placing a piece of wire netting round the plant and filling it in with dry leaves, bracken or some such material. Here a word of warning may be necessary, as field voles often find comfortable quarters here and gnaw the bark, frequently girdling the plants for a few inches above the ground line; thus, where this method of protection is used, it is well to examine the plants frequently. Heather and gorse are very efficient when used for protecting shrubs with short exposed stems. Both are light and dry and do not lie closely, thus allowing a free circulation of air. In addition to this, shrubs of a reasonable size in the open may be covered with a light framework which will support mats or canvas coverings when necessary, or evergreen branches may be used for the same purpose; the latter have the advantage of admitting light and air, and may be safely left on for longer periods than closer coverings. The reed mats so largely used on the Continent for protecting purposes are also very useful, as with some supporting framework they can be quickly placed round moderate-sized plants. One large mat will often cover a small shrub, wrapping it round in the shape of a cone.

In the West I have seen tender bamboos drawn together and matted up for the winter without them taking any injury. Tree ferns, which are grown in some parts of Cornwall, should have some dry material placed on the crowns and then thatched to prevent water lodging in the crowns. Tender palms may have their leaves drawn up and carefully tied together, afterwards covering them with mats or a thatch of reeds or straw.

Plants behave differently in their resistance to frost. Some that are tender while young seem to stand more frost as they get older. On the other hand, young plants often come through a spell of frost that destroys older plants. In woody plants the damage often occurs in the older woody stems, while the younger shoots are unharmed. The injury is nearly always fatal, as the bark is ruptured, and thus all woody portions require protection.

J. COUTTS.

BORDER CARNATIONS FOR AUTUMN PLANTING

IN my last notes on these popular flowers I gave the cultural details essential to success and also mentioned a few noteworthy novelties. In the following article I give some impressions of varieties, both new and old, which I have grown during the past season.

The following are a splendid half-dozen from Crawley Down:

MARY MURRAY.—This is the best yellow self I have grown. It is a vigorous grower and the flower stems are rigid and strong. The flowers are large, of fine form, and the colour is very rich.

MAISIE LOWE.—A beautiful white ground fancy, with large blooms of good form carried on strong stems. The white ground is lightly pencilled with old rose. It is an improved Mrs. P. W. Owen.

ENID LOWE.—This variety gave some exceptionally fine blooms of dainty colouring, midway between Kelso and Pasquin. The apricot ground is daintily barred with a distinct shade of rosy lavender. It has a fine texture and smooth petal.

IVAN LOWE.—A new colour break, this apricot ground fancy, which is rather heavily marked with old rose, is very striking. It is a strong grower with long, rigid flower stems, and the blooms are of perfect form.

KATHIE MOORE.—Though not as large as some of the foregoing varieties, this is a very dainty and prettily coloured fancy. It is a good grower and has a fine border habit. The colour is rose pink on a yellow ground.

LADY SHACKLETON.—This variety gave the finest individual blooms of any of the fancies that I grew. It is almost identical with Lieutenant Shackleton—yellowish rose ground, daintily spotted with pink—but, in spite of its size, it has a perfect calyx, and unlike Lieutenant Shackleton rarely bursts. I was able to gather good blooms of this variety in very wet periods. It is a strong grower and an easy doer. I recommend it for exhibition purposes.

I grew many of Mr. James Douglas' newer introductions, and the following are all worthy of a place in any collection:

MARGARET KEEP.—A very delicate blush-pink clove, which is very fine in dry, sunny weather. It is a strong grower, free flowering, and the flowers are always of perfect form with good calyces. In thundery weather I have noticed that this variety, like all the delicately tinted kinds, is the rendezvous of tiny black flies, which sometimes completely cover the blooms.

Digitized by Google

SCARLET CLOVE.—A heavily scented and brilliantly coloured self that rarely gives a faulty bloom. It is a fine grower, with long, stout flower stems, and it is free flowering.

KING OF CLOVES.—This is a huge flower of deep wine-crimson colouring. It is a very strong grower and the large, perfectly shaped blooms are carried on long, rigid stems. It is very strongly clove-scented.

CORALLINA.—I like the lovely colouring of this variety—glowing coral-pink—and it is very beautiful in artificial light. It is a good grower and the flowers are of fine form with non-splitting calyces.

PURPLE CLOVE.—A very fine purple self of strongest clove scent. It is a good grower, free flowering, and the well formed blooms are borne on long, stout stems.

STEERFORTH.—If I were confined to one dark fancy I should grow this. The white ground is beautifully and regularly marked with rich crimson-maroon and the flowers are large and of perfect symmetry. It has a good border habit and can be grown large enough for exhibition purposes.

ROSALIND.—Soft canary yellow with delicate pencillings of salmon pink make up the charming colour tints of Rosalind, and the flowers are well shaped, while the habit of the plant leaves nothing to be desired.

WHITE CLOVE.—Possibly the most fragrant of all the cloves, this variety makes a huge plant if left undisturbed for two seasons. It has a dwarf habit and is of very strong constitution.

SALMON CLOVE.—The lovely colouring of this beautiful salmon-pink variety and its fine form reminds one of the old favourite, Lady Hermione, but Salmon Clove is of larger proportions. It makes a fine specimen plant and I find it very free flowering. One of the loveliest of the self colours.

In a mental picture of my carnation border at its best I recall the following as being of outstanding merit :

As a dazzling scarlet self I know of no finer variety than GRENADIER. It retains its brilliance in all kinds of weather, but in a dry period it is positively brilliant. It has large, well shaped flowers and these are held erect on good stems.

GLOWWORM is a dwarfer grower, but possesses ideal qualities for border work. It has stiff stems and is very free flowering. This variety winters well in the north.

LOYALTY is a lovely orange-apricot of strong habit, bearing well shaped blooms on stout stems. This variety also winters well and makes a good second year plant.

SALMONEA is still one of the best salmon pinks. When at its best it is a beautiful colour and this variety is nearly always singled out by visitors as being a prime favourite. It is a good grower and very free flowering.

BOOKHAM SALMON is also a very fine salmon pink. It gives large flowers of perfect form and the calyx rarely splits. It has a strong constitution.

There are many very fine crimsons and maroons. The best that I grew this year was FRAGRANCE, a rich crimson-maroon, which is powerfully clove scented.

E. K. WAKEFORD is also a good variety of somewhat similar colouring. The flowers are always of good form and the calyx sound.

CENTURION is a great favourite of mine, a lovely yellow ground fancy, brightly marked with scarlet. Its flowers are always of good shape and size and the calyx is perfect. It has a strong habit and winters well.

THE GREY DOUGLAS is a colour that does not appeal to all, but its lavender is often very silvery looking, and if a few spikes of this variety are mixed with one of the apricot selfs the effect is more pleasing.

APOLLO is a daintily coloured fancy—white ground with clear, light markings of bright red and a picotee edge of the same colour.

Other varieties of merit are : Blush Clove, Bookham Clove (similar in colour to the old-fashioned clove, but of better constitution and form), Maroon Clove, Elaine and Prairie Belle (both good white selfs), Mrs. Hawksbee (white, lightly barred with bright rose), and Bookham Rose, a very bright rose-pink of distinct colouring.

A NEW RHODODENDRON

IN describing under the name Rhododendron Cooperi two specimens of an epiphytic Rhododendron gathered in Bhutan by Mr. R. E. Cooper in 1915 (Cooper Nos. 3959 and 4083), Sir I. B. Balfour writes: "Cooper obtained a third plant of this alliance in fruit only, the field ticket of which runs 'Parshong Timpu. Alt. 10,500ft. . . . No. 3506.' It has a strong resemblance to R. Cooperi, but there are slight differences in foliage that make me hesitate over identifying it with that species. It may be only R. camelliæflorum. We have seedlings raised from seed taken from Cooper's specimens and when they flower a decision of the point will be possible. If the plant is R. Cooperi the description of fruit which I have given will attach to the diagnosis of R. Cooperi." (Balfour, in "Notes of the Royal Botanic Garden, Edinburgh," Vol. X (1917), page 92.

A young plant of this Cooper number (3506) flowered in the Royal Botanic Garden, Edinburgh, for the first time in the beginning of June this year, and there is no doubt it is the same as Cooper's 3959. Two other plants growing under Cooper numbers have this year flowered for the first time also, and are so like the Cooper 3506 plant that in spite of minor differences of foliage and of time of flowering, I am forced to regard them as the same species. Both are growing under wrong numbers, *i.e.*, they do not match the herbarium specimens of the same numbers.

Growth this year has been vigorous, and has resulted in shoots 4ins. to 9ins. long, the lower parts of which carry small arrested scale-like leaves which give place abruptly to normal lanceolate or oblong-oblanceolate leaves 3ins. to 5ins. long and 1in. to 2ins. broad, fairly evenly spaced on the upper parts of the shoots. The small arrested leaves persist through the summer, and are then deciduous, but the normal leaves may persist four or five years. A feature of the young leaves is a conspicuous dusting of the upper surface with comparatively large yellow or white scales. These disappear as the leaves get older, and the upper surface of the leaves one year old is deep green, almost glossy and minutely rugulose with impressed reticulations. On the under side the leaves are densely scaly, at first grey-white or green-grey, later rust-coloured with a punctate appearance due to larger scattered scales of darker tint.

The flowers are not conspicuous and do not readily catch the eye from a distance. Apart from the fact that the flower colour is not a bright one, the flowers are few in a truss, often three, rarely as many as five, very shortly stalked, and congested in umbels that at first are surrounded by the more or less persistent bud-scales and bracts. Moreover, new shoots spring from just below the umbels and are usually well developed at the time the flowers open. On close examination the flowers are rather attractive. The corolla is a deep magenta red, rather less openly cup-like than R. camelliæflorum and is copiously dusted outside with large yellow or whitish scales which are much more conspicuous than the scales on the corolla of R. camelliæflorum. The corolla tube is wide and open and the five rounded lobes form an almost rotate corolla limb about 1in. to 1¼ins. across. The stamens, usually ten, exceed slightly in length the corolla tube, and their thick purple filaments have dense tufts of hairs which, in conjunction with the hairiness of the throat of the corolla, give a circular "eye" of white soft hairiness within the flower cup. This makes a pleasing contrast to the deep colour of the corolla lobes. Then, again, the anthers are large and of bright orange-brown. The short, thick style of a deep purple colour protrudes through the hairs and is curved as in R. camelliæflorum, so that the discoid stigma lies close to the corolla or is thrust between its lobes.

RHODODENDRON COOPERI, BALF. F.
(About two-thirds natural size.)

Two of the plants had the young leaves tinted a rich purple bronze, on the third they were light green. The bronze plants flowered earlier and had slightly smaller flowers than the other, which is a larger and altogether sturdier-looking plant with stouter branches and broader leaves less curved at the margins. The plants showed differences also in the time of making new growth and in the relationship of this to the time of flowering. The first plant to flower, a form with bronzed foliage (Cooper 3506) had young shoots as much as 6ins. long when the first flowers opened. The largest plant of the flowers of which I give a photograph, was three weeks later in flowering and the blooms were already open when the buds of the new growth were beginning to expand. These features may not be permanently characteristic of the individuals, but they suggest that we may be dealing with forms culturally somewhat different from one another.

R. Cooperi is certainly interesting botanically, but I do not think it will prove very attractive horticulturally, nor is it to be expected that it will be quite hardy. The Edinburgh plants flowered in open frames, but they were protected through the winter.

H. F. TAGG.

FRIENDS AND FOES OF THE GARDEN—II

BY CLIFFORD W. GREATOREX.

IT is a true saying that—

He who kills robin or wren
Is good for neither God nor men.

Assuredly, such a wanton one is doing injury to the gardener's interests, for Jenny Wren and Robin Redbreast are two of the most useful of all the birds that help to keep down the insects hosts. With Robin we shall be concerned presently.

The wren seems to be untiring in its quest for hidden prey. Its zeal is unflagging. Into the deep recesses of ivy, and the intricacies of hedgerows, and the labyrinths of undergrowth will Jenny go, intent only upon one object—the discovery of insects. She seeks insects in all their stages of development—as eggs, as larvæ, as pupæ and as imagines. The insect's egg that escapes her penetrating little eyes must be minute indeed! During most of the year, Jenny feeds on only small insects and kindred creatures, but, when these are scarce, as they are in the heart of winter, quite large chrysalids are devoured. I have seen her disposing eagerly of the chrysalids of white butterflies. The gardener has sound reason to be profoundly thankful to any bird that helps rid his domain of the cabbage butterflies. Jenny's winter-time activities save him many hours of wearisome caterpillar-hunting at a later date.

No less familiar is the robin, whose song is one of the sweetest of all the accompaniments of autumn. Robin is as useful as he is charming. He is by no means dependent upon our offerings of crumbs and scraps, but throughout the greater

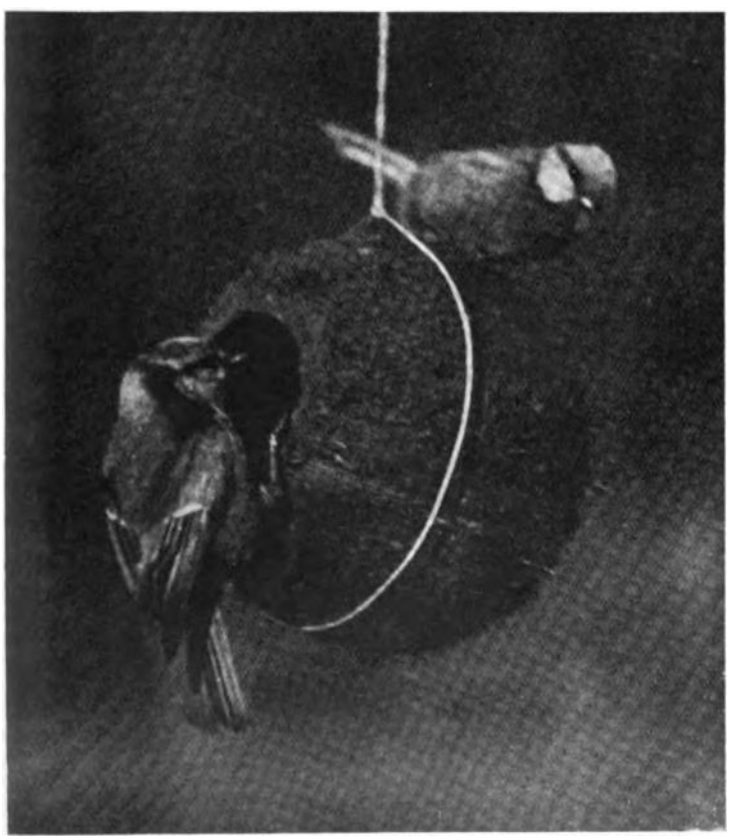
Digitized by Google

part of the year this active bird wages continual warfare against harmful insects. Often he will catch flies on the wing. Plump caterpillars are his especial delight, and I have heard him "clicking" away excitedly upon discovering a row of bushes infested with the larvæ of the gooseberry sawfly. During the time when there are young to be fed, robin's activities increase very considerably, and his services as a pest-destroyer become greater accordingly. In the chilly months of the year Robin does good work by capturing the winter moths, against whose ravages even the stickiest bands of bird lime are not always effectual. Sometimes he will hunt the fluttering males of this species until the darkness renders the pursuit impossible. There is no need to dilate more fully upon the extent of Robin's utility. He is well established not only in the favour of the gardener, but in the esteem and goodwill of mankind in general.

All the titmice are beneficial and they are as attractive in appearance as they are useful. Best known among them are the great tit and the blue tit. The great tit, by the way, is a pugnacious bird that, given the opportunity, will not hesitate to pick out the brains of a captive or injured member of its own kind.

Admittedly titmice are very fond of young buds, but as a rule the buds destroyed are already infected by insects. Charles Waterton would never allow the tits in his orchard to be interfered with, and the birds abounded there. Yet his fruit crops were always good, even when those of his neighbours, who would not tolerate the tits, were poor. Concerning the great utility of the blue tit, that distinguished authority, Dr. Coward, remarks: "No species destroys more coccids and aphids, the worst foes of many plants." These birds have been known to consume American blight. Great numbers of the caterpillars of leaf-miners are devoured, and even the sudden descent by silken threads cannot save them, for the titmice poise on vibrant wings and adroitly seize the hapless grubs. And, were the latter to remain in their shelters, they would be pulled out relentlessly by the keen-eyed little birds. I have seen both great tits and blue tits picking the larvæ of currant moths from the bushes with great assiduity.

The song thrush, the mistle thrush and the blackbird are species that render very great service by destroying slugs, snails, caterpillars, many kinds of beetles and various other



ALTHOUGH SOMETIMES MISCHIEVOUS, BLUE TITS ARE USEFUL IN THE GARDEN.

THE BLACKBIRD'S COIGN OF VANTAGE

insects, although they are partial to ripe fruit during a necessarily limited portion of the year.

Everyone has seen snail-stones; those stones on which the thrushes (both song thrush and mistle thrush) smash the shells of their molluscan victims. Judged by the abundant litter often surrounding these stones, the number of snails disposed of must be very great indeed. The berries most in favour among these handsome birds are those of ivy, yew, hawthorn and mistletoe.

As to the destruction of garden fruits, careful observations have proved that, in this respect, the blackbird is a greater offender than is either the mistle thrush or the song thrush. Pears, apples and raspberries are irresistible to the "golden-bill," but, before imposing sudden death upon him it is advisable to settle in one's own mind whether or not the good he does by destroying slugs and snails and so-forth is not greater than the injury he inflicts upon one's cherished fruit. A bird that is highly beneficial throughout, say, ten months of the year, but lapses into what seems to the gardener to be sheer thievery during the remaining two months, is hardly bad enough to be shot down as though he were a freebooter from the first day of the year to the last! It is better to take every possible measure for the protection of one's fruit without causing the blackbirds to pay the death penalty.

The starling is another bird that alternates long periods of good service to the gardener and the farmer with short intervals of mischievousness. Multitudinous are the insects devoured by this engaging and lively bird, and included among them are pests such as weevils, wireworms, many kinds of harmful flies, while slugs and caterpillars are consumed with noisy eagerness. I have seen a couple of starlings seize a huge black slug, hack it into pieces, striving meanwhile who could swallow the greater portion of the very frothy tit-bit!

When the pears are ripe, the starlings show their appreciation of these succulent fruits all too freely. But, the gardener is not always obliged to resort to the use of his gun. A stuffed hawk, placed in an exposed position, has been known to keep the starlings away from even the most tempting of heavily laden pear trees. Or, better still, a live hawk, borrowed from a falconer, or trained from the nest, and secured where the clamorous birds could not fail to see it, is a warning that not even the boldest of starlings would fail to heed!

Of late years, starlings have been rapidly on the increase, largely owing to the amount of protection which they enjoy, and also to the fact that they can move rapidly from place to place according to whether food is scarce or plentiful in a certain area. In winter, when the nights become colder, these birds congregate in large flocks which frequent marshy districts, and then in the day-time, they spread over the fields in search of their insect food.

HUNTING SEMPERVIVUMS in the CANARY ISLANDS

BY DR. R. LLOYD PRAEGER.

DR. PRAEGER VISITED THE CANARY ISLANDS TO ASSIST IN CLEARING UP THE CONFUSION WHICH REIGNS IN THIS GENUS.

THE distribution of the genus sempervivum (using the term in its wider sense) is peculiar and interesting. One half of the group (sempervivum proper) is spread across Europe from the Pyrenees to the Caucasus, reaching its maximum on the Alps, with one outlying species (S. atlanticum) on the Atlas mountains in Morocco. The other half, some sixty species, is centred in the Canary Islands and Madeira. These latter plants differ much from the European section and from each other, ranging from soft annual herbs to massive sub-shrubs forming bushes several feet high, and the tendency among modern botanists is to group them in four separate genera—Æonium, Aichryson, Greenovia and Petrophyes (Monanthes).

In European botanic gardens these Canarian plants are well represented, but as regards their nomenclature they are in a state of confusion equalled only by their Alpine cousins. By the kindness of many fellow-workers I amassed during the last two years a collection of some 350 plants from gardens situated anywhere from Scotland to Servia, and from Portugal to Finland. The names under which these plants arrived represented every known Canarian species, and included others as yet undreamed of in our philosophy. But the plants! Some twenty species could be identified, masquerading under more than twice as many appellations; but the balance included a welter of plants intermediate in character and often merging by degrees into one another, which proved impossible to name and rendered the identification of the good species the more difficult. These were evidently mainly garden hybrids of undetermined origin, and their presence confused the whole issue. It was plain that garden material alone offered but little help. Salvation lay not that way, and accordingly I arranged to spend three months on the islands, collecting and studying the group in its natural home. It may be said at once that one did not thus get away from the confusion which hung over the genus, for the records of the local distribution of the different species proved often erroneous or vague, and to a considerable extent one had to begin *de novo*.

However, we landed (my wife and I) with high hopes on Tenerife on March 6th, and I felt a thrill when, motoring to Orotava, I saw my first wild Canary sempervivums—big palm-like plants of Æonium urbicum on roadside walls, followed farther on by the branched tree-like Æ. holochrysum, and on rocks near Orotava the flat green discs of the remarkable Æ. tabulæforme, one of the most curious of the whole group, and the soft hairy leaves of Aichryson annuum (dichotomum). I may say at once that the subdivision of the Canary plants into four genera—Æonium, Aichryson, Greenovia and Petrophyes—seems, after study on the ground, to be well justified.

The Canary archipelago includes seven islands—"Tenerife and its Six Satellites"—three lying eastward of Tenerife and three westward. We proposed to explore all and, after a few days at Orotava to establish a kind of base camp, we took the inter-insular boat for Fuerteventura, 150 miles to the north-east. Fuerteventura is a large island sixty-three miles in length, and is the least fertile of the group on account of its very small rainfall, due to its position and its comparatively small elevation. In exploring it and the other outlying islands we had the advantage of the company of Dr Oscar Burchard of Orotava, whose knowledge of the country, the language and the plants was very valuable. Landing at Grand Tarajal, we struck southward for the mountainous peninsula of Handia, across mere desert, "desperate and done for," sometimes of black stone, sometimes of white sand, trekking on camels by day and sleeping under the stars at night. On the afternoon of the third day we reached the summit of the Pico de la Zarza (2,770ft.), the highest point of a lofty ridge which on the north-western side fronts the ocean in a magnificent fifteen-mile range of enormous cliffs. In contrast to the desert valleys behind, these cliffs have a luxuriant vegetation, due to condensation as the ocean winds strike them. Here we got Aichryson pachycaulon (?); this is its only known station, and it has apparently never been collected since Bolle discovered it in 1854. Petrophyes agriostaphys was here, too. Next day we got another of Bolle's endemics, A. Bethencourtianum, when crossing the pass which leads down to Cofete. This was all we succeeded in doing in Handia, though a couple more endemic sempervivums called aloud for re-discovery. The great difficulty of securing food, water and shelter (we "slept out" for a week) drove us northward again. We reached Monte de Cardon, a fine upstanding cliff-walled hill of 2,200ft., but it was too dry for sempervivums (which are by no means desert plants) and, abandoning our camels at Tuineje, we motored north to Oliva, where a slightly greater rainfall produces comparative fertility. Here we collected A. pulvinatum, which proved to be indistinguishable from the well known A. pygmæum, and also, but in a station open to suspicion of introduction, the fine Æ. balsamiferum. We left Fuerteventura after twelve days' work with only five species to our credit—no more than we had seen on the first half-day on Tenerife.

Photo Dr. Oscar Burchard.

ÆONIUM CANARIENSE IS WIDELY DISTRIBUTED OVER THE ISLAND GROUP.
Note the small white stick which measures ten centimetres.

Lanzarote, the most eastern of the islands, was explored next. Haria, our destination, was an oasis full of palm trees and crops. The town lies among high hills, which on the west drop into the ocean in a long line of magnificent 2,000ft. cliffs. This was our best ground, but its exploration was rendered difficult by a persistent gale of wind which made cliff-climbing a dangerous form of exercise. However, I crawled along ledge after ledge, and

Digitized by Google

had the satisfaction of finding Æ. balsamiferum unquestionably native, another Æonium not yet determined, A. pygmæum, P. agriostaphys and plenty of Sedum lancerottense, first found near here by the Rev. R. P. Murray, and still the only known Canarian stonecrop, except for the annual S. rubens. Inland cliffs and rocks yielded all these species again, except the first.

From Lanzarote we passed to Grand Canary and, motoring through the coastal sub-tropical desert zone, reached the hill region, where green fields, bushes and trees formed a welcome contrast to the barrenness of the eastern islands, and where for the first time we revelled in a rich sempervivum flora. The barranco on the edge of which our fonda at Valsequillo was built was full of Æ. Manriqueorum and one or two others not finally determined, the handsome Greenovia aurea, A. punctatum, A. annuum and P. brachycaulon. Tenteniguada, a few miles away, is a glorious place, with great gorges, cliffs and pinnacles vying in picturesqueness with the best pieces of the Alps, though the highest point is only some 6,000ft. Here we saw for the first time the beautiful Æ. cæspitosum, and also a very large yellow-flowered species which appears to be new. All these plants were seen repeatedly as we wandered westward along the hills by San Mateo to Firgas, a mule carrying our baggage. In the great Barranco de la Virgen the large downy-leaved Æ. virgineum came in in millions, to the exclusion of almost every other sempervivum. Cuesta de Silva, a glorious gorge down by the sea, proved a very garden of sempervivums of the species named above, and along with the splendid crater called Caldera de Bandama, it also yielded Murray's Æ. percarneum, a fine plant much flushed with red. We left Gran Canaria with regret.

We now turned our attention to Tenerife for a short period, and explored the north coast, past the great cliff ranges at San Juan de la Rambla, starred with innumerable Æ. canariense and Æ. tabulæforme, to Icod de los Vinos, which proved a good centre. Here the scarps formed véritable rock gardens decorated with the two last-mentioned species, bushes of Æ. holochrysum, hanging masses of P. agriostaphys and plump reddish clumps of the beautiful P. polyphyllum. We pushed on westward to the very perfect little volcano called Montañeta de Taco, whose slopes and crater have a fascinating desert vegetation. Here Æ. Haworthii is abundant, and we also secured the rare Æ. sedifolium, with small green and scarlet leaves.

Back in Orotava, we made an expedition on mules to the Roques de Guimar on the southern slope of the island, up through the cultivated zone to Agua Mansa, where Greenovia aurea starred the cliffs in thousands, through the Retama zone, over high screes almost devoid of vegetation, across the ridge at 6,500ft., and down into a vast savage crater. Here, in a gorge in the many-coloured crumbling volcanic rocks, we got Æ. strepsicladum, the remarkable Æ. Smithii and the rare Greenovia rupifraga.

Photo Dr. Oscar Burchard.

AICHRYSON PACHYCAULON GROWING IN ROCKY CLEFTS ON FUERTEVENTURA.

Photo Dr. Oscar Burchard.

ÆONIUM SEDIFOLIUM, ONE OF THE RAREST OF ALL SEMPERVIVUMS.

Anaga, the narrow eastern end of Tenerife, is composed of very old volcanic rocks, which have been carved into mountains and gorges fantastic in their ruggedness. Laguna forms a good strategic centre for the exploration of this region, which is of deep interest to the botanist, for from Laguna one easily reaches a bridle path which leads for miles at an elevation of about 3,000ft. along the backbone of the promontory, affording easy access to the pinnacled ridges and deep valleys which drop steeply down to right and left. We spent several delightful days in this region, securing the fine Æ. cuneatum, like a glaucous Æ. canariense with rosettes 1½ft. across, the thick-leaved Æ. Lindleyi, the very rare Greenovia gracilis, and a remarkable Petrophyes for which I have not yet discovered a name.

We landed on Palma on May 4th, with a feeling of regret that the vagaries of the inter-insular steamer service allowed us only seven days for the exploration of this lovely island. The time was spent in working up and down the east coast from Fuencaliente, at the southern end, to La Galga, and in the great barrancos behind Santa Cruz de Palma. The southern region consists mainly of lava flows, cinders and pine woods. Here the very local Æ. cruentum has its headquarters, growing often on the bare lava, where in summer it is burned to a leafless twiggy bush. With it was a Petrophyes still unnamed. The grand barrancos near Santa Cruz, whose precipitous wooded sides rise for up to 2,000ft. above the cañon-like stream-courses, were full of Æ. palmense (the Palma representative of Æ. canariense) and other more familiar species. Tramping northward from Santa Cruz, we had the good fortune to find a remarkable Æonium which is undoubtedly new—a massive plant, with thick, sticky leaves larger than a man's hand, a solid unbranched stem, and a large flat-topped inflorescence. Further on the pink-flowered Æ. Goochiæ became exceedingly common. Like many of the Canarian plants, its world-range is limited to portion of one island of the group. The Barranco de la Galga was searched for another endemic species, Aichryson parviflorum, recorded only from there. We were rewarded by an equally rare species, A. palmense, previously known only from a spot further north. Night overtook us entangled in a succession of great gorges crammed with sempervivums. We found refuge in a kind of cellar under a tiny shop, and next day rode back rejoicing to Santa Cruz.

We next raided the small island of Hierro. The principal town, Valverde, lies at 2,000ft., and the aspect there, though pleasantly green, is somewhat bleak. But it proved rich in the group which I was working. In a crater above the town and in neighbouring gorges the grand Æ. hierrense grew in profusion—a noble plant 2–4ft. high, with an unbranched stem terminating in a huge inflorescence, up to 2ft. long and 1½ft. across, of thousands of pink blossoms. With it were the tall yellow spires of Æ. canariense, and an interesting series of hybrids between these two. Another fine Æoniu

Digitized by Google

undescribed, was abundant also, especially in the lower regions—a rather symmetrically branched plant several feet in height which hybridised with both hierrense and canariense. Petrophyes muralis, another addition to our collection, grew on house walls just outside our bedroom window. We made a four-day excursion on mules to the western part of the island. At El Pinar Æ. cruentum grew in its only station outside the island of Palma. Also our new Valverde Æonium and several other species already collected elsewhere. Then through forests of stately Pinus canariensis and across the island to El Golfo. This is a fertile slope enclosed on three sides by a semi-circle of gigantic cliffs 3,000ft. in height, and on the fourth by the ocean. The cliffs are literally clothed with sempervivums, especially Æ. canariense and G. aurea. The endemic Æ. hierrense was here, too, hybridising as at Valverde with Æ. canariense.

Our last island, Gomera, to visitors perhaps the least known of the group, proved to be possibly the most beautiful and interesting to us. From San Sebastian, the capital, standing on a sandy bay, where we first stayed, an immense branching barranco leads inland to the wild forested interior. Here grew in abundance three species all of which are confined to Gomera—Æ. viscatum, Castello-Paivæ and (more locally) Saundersii, all very distinct and characteristic plants. Æ. canariense was abundant also in a peculiar form, probably deserving sub-specific rank, the leaves very narrow below and exceedingly broad above, disposed in a flat rosette resembling tabulæforme, the inflorescence very narrow. At the pass or Degollada leading across to Hermigua, where the vegetation was composed mainly of sempervivums, we got a new species, allied to Castello-Paivæ, but quite distinct. The neighbourhood of Hermigua, with its great cliff-walled valleys and lovely moist forests of laurus and erica, proved fascinating. Æ. viscatum and Æ. Castello-Paivæ were abundant. Perhaps it is the great abundance of the few species which occur which accounts for the finding on Hierro and Gomera of a number of natural hybrids, hitherto considered very rare in this genus. We got Æ. canariense × viscatum, canariense × Castello-Paivæ and Castello-Paivæ × viscatum, also a Petrophyes still undetermined. Thus Gomera, though quite a small island, added considerably to our collections.

We had now to hurry home, for a large quantity of living material had been amassed from the different islands—235 gatherings in all. Of these two (both Petrophyes) collected early in our tour died during our absence on the western islands. Of the remaining 233 all arrived alive in Ireland, owing largely to the kindness of Captain Pope of the Yeoward liner Alondra in placing at my disposal an empty stateroom. Here all the plants were spread out to the air and light, and without water they actually improved on the voyage.

In these notes I have "stuck to my text" and dealt merely with the collecting of the group at which I am working.

(Photographs by Dr. Oscar Burchard.)

SHOWS AND SCHEDULES

BY EDWIN BECKETT.

(Continued from page 734.)

FOR the second part of these notes we will briefly consider the shaping of schedules, for average societies, for three periods, viz., for a show say about the middle of April, for a show about the end of May, and for one early in September. The ideas set out can, of course, be modified to suit local conditions, as will undoubtedly be necessary, and it should be further borne in mind that the suggestions are made for the neighbourhood of London, therefore southern societies will realise that their conditions will permit earlier efforts up to as much as ten days, and the northern associations will be able to modify the dates for a period of up to a fortnight later. Before considering the suggestions in detail, it is well to state that, for a society that only runs one show each year, the ideal period is probably from the middle to the end of July, weather conditions being about the average, and therefore it would be well to aim for that time as far as possible.

MID-APRIL SHOW.—At this time of the year it would be well to understand the effort to be principally for the benefit of those who raise spring bulbous plants, and therefore it should be a spring flower show, the prime attraction of which will be daffodils, tulips and hyacinths, the chief classes being allotted to these.

Classes for daffodils could comprise, say, a collection of twelve distinct varieties, twelve (or six) stems to a vase. Similar collections of six distinct varieties, vase of twelve trumpet daffodils all one variety, twelve stems to form a vase, and other classes for the other types such as the Leedsii, the poeticus, the Barrii, etc. Other classes could be formed for hyacinths grown in pots, or fibre, and call for, say, a collection of six distinct varieties, or for a collection to occupy a certain table space, and then minor classes for colours. Other classes could be formed for tulips and early spring flowers, such as wallflowers, violets, polyanthus (an especially enticing class), and even for roses and carnations grown under glass, if there are growers who can fill the bill with these, but they should be omitted if the members of the society do not go in for glasshouses. Another fascinating group that would probably be well looked after by enthusiasts, are rock plants, and a class could be included for a table rockery, to cover a space not exceeding certain limits. In addition, form a class for twelve distinct rock or alpine plants grown in pots or pans, and a smaller class for six plants. Early-flowering herbaceous plants could well form a small class, say, for three vases of distinct kinds. Another good class could be formed for, say, six vases of cut material from early-flowering shrubs and trees. Table decoration classes should not be omitted, and those very charming classes of wild flowers and grasses, for children's competition should certainly be included. Finally, for the vegetable enthusiast, classes could be formed for rhubarb, asparagus, cabbage and broccoli, which would be the chief probabilities at such early period, and as the efforts of the members grew, so the classes could be extended annually for vegetables in order to entice them to attempt forcing under glass in heated pits and frames on hot beds.

THE END-MAY SHOW.—This could be a general effort period, and vegetables commence to take a more prominent position, so that a class for three distinct kinds of vegetables (or more if the cultural efforts are well established and of high level), with separate classes for early broad beans, leeks, onions (autumn sown), cauliflowers, etc., such as might be likely to be in season at this period in particular localities. Again, classes for small table rockeries, and cut flowering shrub and tree material, as also for the table decoration and wild flowers should be formed, and good classes for collection of perennial flowering subjects, as well as single vases of different kinds. Inducement to interest those who went in for stove and greenhouse plants should be added, and a class calling for an ornamental group of such plants formed, as well as classes for isolated plants, under different kinds, included, such as a class for the best three pots of begonias, qualifying this for tuberous-rooted varieties if desired, and even a separate class for other varieties. Incentive should also be given to growers by the formation of a class for early (forced) strawberries, calling for a dish of, say, twelve, eighteen or twenty-four fruits, and another class might even be formed for grape growers, for careful storage methods should permit quite a nice display of this attractive fruit.

EARLY SEPTEMBER EXHIBITION.—There need hardly be very much limitation to the effort for this period of the year and here I will tabulate classes to save space:

Plants in pots:

Three window plants, distinct kinds in pots, not to exceed 8ins.
Three fuchsias, distinct varieties. Pots as above.
Three geraniums, distinct varieties, etc.

Cut Flowers:

Twelve bunches (or six) hardy border flowers, not less than nine (or four) distinct kinds, excluding annuals, biennials, shrubs and trees.
Three bunches (or vases) ditto, ditto.
Six cut roses, in vase, with own foliage.
Three ditto.

Digitized by Google

Best arranged bowl of roses, any variety, with own foliage, no other foliage permitted.
Six cactus dahlias, not less than three distinct varieties.
Six dahlias in not less than three distinct varieties, excluding cactus.
Six vases of chrysanthemums, not less than three distinct varieties.
Three vases ditto, ditto.
Three vases of Michaelmas daisies, distinct varieties.
Classes for violas and show pansies, calling for say twelve and six distinct varieties.
Three vases of antirrhinums, distinct varieties.
Vase of gladiolus, not less than six spikes.

Fruit :

Collection of four distinct kinds.
Collection of apples. Six distinct varieties, six fruits of each.
Collection of pears. Six distinct varieties, six fruits of each.
Collection of plums. Three distinct varieties, six fruits of each.
Apples, dessert. Dish of six of any one variety.
Apples, culinary. Dish of six of any one variety.
Pears. Dish of six of any one variety.
Plums. Dish of nine of any one variety.
Damsons. Dish of twenty of any one variety.
Cherries. Dish of twenty of any one variety.
Figs. Dish of six of any one variety.
Red currants. Dish of twenty stalks, as grown, of any one variety.
Raspberries (autumn fruiting). Dish of twenty fruits.
Nuts, filberts or cobs. Dish of twenty of any one variety.

Vegetables :

Collection of six distinct kinds . Size of the dish to be in
Collection of four distinct kinds . accordance with the numbers set out below for single kinds.
Collection of salads. Four dishes each, comprising a distinct vegetable, used uncooked as a salad. Beet may be included, and mustard and cress to count as one kind.
Potatoes (two dishes). Nine round and nine kidney, one variety of each.
Potatoes. Nine round of any one variety.
Potatoes. Nine kidney of any one variety.
Six onions, winter sown, of any one variety (*i.e.*, sown under glass and planted out in spring.)
Six onions, spring sown, in bed, of any one variety.
Four beet of any one variety, long.
Four beet (round) of any one variety.
Six turnip of any one variety.
Six carrot of any one variety.
Four parsnips of any one variety.
Twenty-five pods of runner beans of any one variety.
Twenty-five pods of peas of any one variety.
Six leeks of any one variety.
Two vegetable marrows of any one variety.
Three cabbage of any one variety.
Two cabbage (red) of any one variety.
Three cauliflowers of any one variety.
Three celery of any one variety.
Six tomatoes of any one variety, red or yellow.
Twenty shallots of any one variety.
Twenty brussels sprouts of any one variety, to be shown off stem.

So much for the main sections, which can, of course, be modified to suit local conditions. To finish off the programme, classes can be formed for rock plant collection, table decoration, floral or this could be extended in scope to permit of decoration with fruit and floral work, to comprise a table set out for dessert. Other items could be a buttonhole class, classes for vases of flowers arranged for decorative effect, vases of wild flowers for children's competition, and one that should specially be added if well into September, is a class for a bowl of autumn foliage and berries arranged for effect. This latter class of decorative material is too frequently overlooked, and I should like to see more effort directed towards this, so that classes may appear in schedules calling for say a dozen vases of distinct kinds of autumn foliage or berries, as fine ornamental effect would thus be given to the showroom, and the beauty of these items for home use would then be more fully realised. In conjunction with this idea I would recommend to the schedule makers a class for a vase of rose hips, the fine effect of which would surprise their visitors to the show.

Just a final word, the foregoing is only intended to suggest a reasonable programme for a schedule, but, of course, the compilers will have to use discretion, according to their class of exhibitors, and not necessarily hold fast to the ideas set out, but utilise them to meet their own needs.

CORRESPONDENCE

GARDEN IN NEW ZEALAND.

SIR,—Your article on "The Purpose of Wisley," page 444, in suggesting a modification of educational methods there, remarks "but I happen to know the scarcity of matured gardeners, not only in this country but in the colonies . . ." You have certainly stated a fact as regards this Dominion. Yet it is not to be wondered at. The status of a gardener here is scarcely better than that of a labourer; in most places employing such he has to be a good deal of a "rouse about," as a man doing any odd jobs and rough work is often termed. Decent opportunities of employment for thoroughly trained gardeners are few and far between, and commercial horticulture gives better opportunities for such men, who are thus lost to the profession. A few juniors—very few—become apprentices to the nursery trade, and then, mostly, sooner or later get on to some other and better line from a paying point of view. I am concerned here in the horticultural trade, and know only too well that remuneration is not in keeping with knowledge and responsibility, but an enthusiasm keeps me to it. However, this is somewhat by the way.—A. H. SHRUBSHAW, *N.Z.*

EUCOMIS PUNCTATA.

SIR,—I showed Mr. Canning-Wright's article on "South African Bulbs" to a friend of mine, who lived in South Africa for many years. He says the Eucomis punctata is quite familiar to him, but when he saw it it was *blue* in colour and grew in profusion in the garden of the late Mr. Cecil Rhodes.

Can any of your readers tell me if it is possible to procure *blue* Eucomis punctata bulbs in England? If so, they would be even more attractive than those described by Mr. Canning-Wright.—VICTORIA SLADE.

FURCRÆA LONGÆVA.

SIR,—Your readers may be interested in the enclosed photograph of a Furcræa longæva in flower in the open. The plant is situated in the grounds here on a grass bank with a south aspect a quarter of a mile from the sea. It was grown from seed brought from the Scilly Islands by a former tenant nineteen years ago. Last May, for the first time, it showed signs of activity and in two months had thrown up a flower spike more than 14ft. high. The effect of the innumerable white blossoms on drooping green stems was very pleasing.—BEATRICE MILDMAY, *Holbeton, Plymouth.*

A BEAUTIFUL MEXICAN FURCRÆA.

FUCHSIAS.

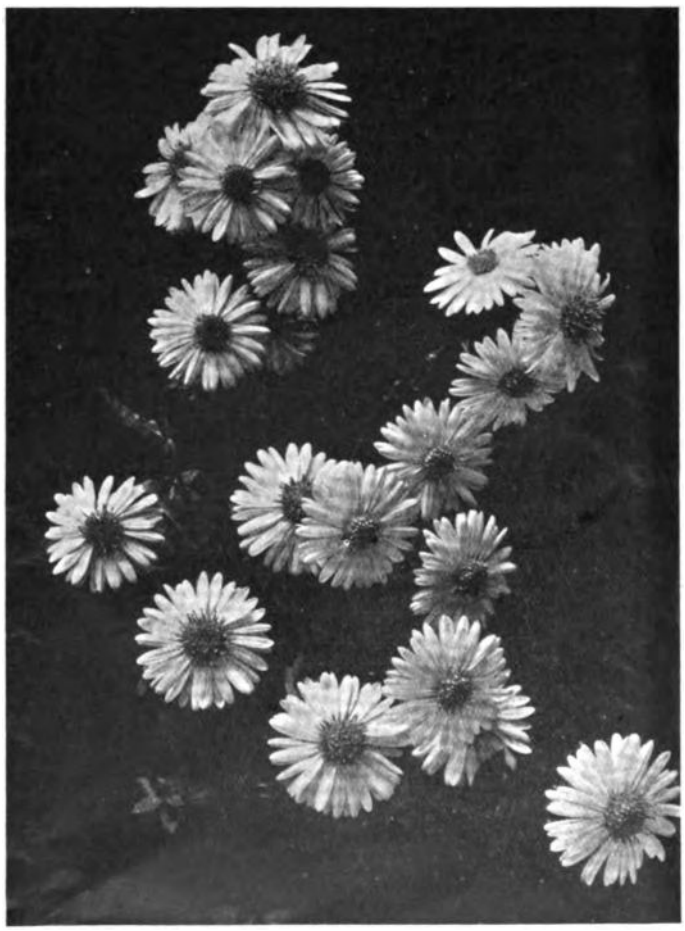
SIR,—Mr. Coutts in his very excellent article on fuchsias mentions the plant that came into the possession of Mr. Lee, the Hammersmith florist. This was a plant of Fuchsia fulgens brought from Mexico, but it was not the first fuchsia to be received here, for, according to the *Botanical Magazine*, Fuchsia coccinea had been growing in the Stove at Kew since 1788, and F. lycioides arrived from Chili in 1796. About twenty years later quite a number of fuchsias came to this country from Mexico and Chili—microphylla, gracilis, virgata, macrostemma and one from New Zealand, excorticata. Fuchsis corymbiflora was stated to be raised by the late Mr. Standish of Bagshot, and Dr. Lindley observed that it cast all other fuchsias into the shade, but in a book on the Peruvian flora this variety is described as magnificent, growing to a height of 6ft. and laden with flowers, making it appear a native of Peru. It is a beautiful flower, the long tube of clear rose, the much reflexed sepals deep rose, with corolla of brilliant carmine. Fuchsia fulgens used to be grown extensively for bedding. I remember seeing many years ago at the Crystal Palace a huge

Digitized by Google

bed of these plants covered in bloom and making a very beautiful display. Riccartoni is a grand hardy plant. Three years ago my specimen was 9ft. high and 9ft. through, with myriads of its pretty scarlet and purple flowers, but the severe winter cut it to the ground, though it had escaped injury for nearly twenty years, being in a sheltered spot. It is now about 7ft. in height and has flowered well. In an old florists' book published in 1844 there is a list of ninety-six named sorts and a capital coloured plate of a variety with the queer name of Money-pennyi with long, slender tube of rosy red, sepals same colour, with deep red corolla. Some of the very old favourites still continue to be grown, notably Rose of Castile and Mme. Cornelissen.—J. P., *Cheltenham.*

ASTER CLIMAX AS GROWN BY A READER.

SIR,—I hope the enclosed photograph of Michaelmas Daisy "Climax" grown as advised by the Rev. J. Jacob, will interest your readers. The picture is of two horizontal sprays from single stem plants of an average height of 6ft. and covered in blossom. The plants are really a glorious sight during these autumn days. I was much interested in the illustration "Nail-Galls on Lime."—C. LACEY, *Wimbledon.*



TWO FINE FLOWERING SPRAYS OF ASTER CLIMAX.

CATALOGUE DESCRIPTIONS.

SIR,—I agree to a certain extent with your correspondent as to the failings of nurserymen's catalogues as set out by "E. H. M. C." in the issue of October 25th. A, B, C, D are necessary in case of new plants. E seems to me unnecessary except in case of some plant which "ramps" badly, *e.g.*, eryngium, epilobium or montbretia. In these cases a word of warning would not be amiss. F.—Desirable, but not absolutely necessary. G.—Until a universal colour chart is used there would appear to be no hope of accurate description. To this list I would add H.—Height of flower. At present a few catalogues give this, but even this small and select band are divided as to whether the height of the plant or height of flower should be given. The height is chiefly important in the rock garden, and it is just there that the catalogues fail us. It is useless describing plants as "dwarf." A dwarf in one rock garden is a giant in another. The maximum height should be given. I have never yet found a catalogue giving the height of dwarf conifers for rock gardens, hence I have never yet bought a dwarf Pinus sylvestris, as nowhere can I find its maximum height, and it would go to my heart to have to root up a flourishing tree solely because it had grown too tall. Some catalogues give cultural notes for each species. This appears to me sufficient unless one variety differs greatly from its relations. If it does, the fact can be stated. One catalogue has a code on the inside of the cover to meet the needs of each plant. Thus A, Sun; B, Shade; C, Dry situation; D, Moist situation; E, Likes lime; F, Dislikes lime; G, H, I. etc.; and after the name of the plant there appears the letters B, D, K, P, S, and so on according to its requirements. In case of doubt as to treatment of plant it is only necessary to turn to the code. This is cumbersome, but useful. If nurserymen complain that a little more description would add to the cost of the printing, they might economise by omitting the "Choice collection, our selection." Does anyone buy these collections? One of the joys of gardening is the selecting. On a winter's evening it is a delightful occupation to go through a catalogue marking the plants one would order if space, and purse, allowed. No "Collections, our selection" for me. Again, would a full description take very much more room if condensed. For example, "Viburnum fragrans.—Chinese deciduous shrub. Hardy. Handsome foliage. Quick grower, 12ft. or more, 6ft. diam, Jan.–Mar., numbers tubular flowers (? ins.), shell pink or white, fragrant. Moist loam. No pruning. Flowers stand 10° frost. Does not flower freely till fourth year." You will notice I have omitted "good habit," as this phrase has always been meaningless to me. Also "likes lime," as a note at beginning of catalogue can state that all plants therein can stand lime unless the contrary is stated. The same can be done with "hardy." But on the whole catalogues are not so bad. I could give a list of some half a dozen which need but very little modification. The size of the actual flower would be a useful guide sometimes instead of "large flower." The height of perennials would be the average height in a normal year. Delphiniums are not always 8ft. tall nor hollyhocks 17½ft. Let us hope this year was exceptional, it made staking such a problem. In conclusion, I *do* agree with "E. H. M. C." that where prices are approximately equal the nurseryman with the most descriptive and fullest catalogue will get the order. I do not think that he always realises that in almost every case his catalogue is in competition with five or six others before the order is given, and that the customer will not bother to write asking for details.—HUMPHREY SWANN, *Wimbledon.*

SIR,—"E. H. M. C.'s" article on catalogues is most interesting, and I think from the purchaser's point of view the specimen suggested is excellent. But—and a very large but—the nurseryman says, and very naturally, to print twelve lines on each plant is too costly in space and time. The catalogue would become a volume. Taken on the whole the average catalogue gives height, hardiness—which again is very difficult to vouch for—colour, and very often aspect is included. It seems to me asking too much to have the whole history of the plant given, as well as price, etc. Garden books abound nowadays, both cheap and dear, and if you are interested in your garden you must have some to refer to. What I find catalogues fail in is telling you that what they describe as a quick-growing trailer is really the most poisonous weed to get into your rock garden. I once put in Coronilla varia, and in a year it had choked every plant near and come out yards away from where it started, and there are many others equally dangerous.—N. S. C., *Godstone.*

THE NEW ZEALAND INSTITUTE OF HORTICULTURE.

[It may interest many readers of THE GARDEN to learn of the rapid progress that horticulture is making in this far flung outpost of the Empire. Great strides have been made during the last few years largely owing to the efforts of a few enthusiasts and also to the backing and impetus given by the New Zealand Government.—ED.]

SIR.—On August 5th the second annual meeting of the Dominion Council of the New Zealand Institute of Horticulture was held in Wellington, with Mr. J. A. Campbell, President, in the Chair, and a large number of delegates from all parts of the Dominion, including many of the leading horticulturists and some prominent scientific men, were present Dr. L. Cockayne, F.R.S., was elected Dominion President and also Hon. Botanist; Mr. George A. Green, Dominion Secretary; and Mr. H. Baillie, Hon. Secretary of the Executive. The meeting opened with an address from the Hon. W. H. Nosworthy, Minister of Agriculture, who congratulated the Council on the fact that the Institute was fairly launched and expressed his belief that it would be of great benefit to the Dominion. Many important matters were discussed, including education in horticulture from the primary school to the University, plant quarantine, revision of nomenclature for all classes of plants grown in New Zealand, affiliation of horticultural societies and public bodies, certification of plants, bud selection and publication of bulletins—the *New Zealand Fruitgrower* being made the official organ of the Institute. The Government has made a grant of £150; members are being enrolled from all parts of New Zealand, district councils have been set up in the chief centres, so now all the machinery is in place for making the Institute a national undertaking which must have a most beneficial effect on the horticultural development of New Zealand.—L. C.

NOTES FROM CONTRIBUTORS

WAYSIDE FLOWERS OF GREECE.

HERE in this corner of Greece I have as yet seen no show of flowers so splendid as the crimson peonies on Kossovo battlefield, of which I wrote some time ago. (July 5, page 473.) But the wild hollyhocks have been a splendid sight. Where the forest has been burnt they have come up like the foxgloves in woods at home: tall sheaves of them 6ft. to 8ft. high, with big, mallow-pink flowers not regularly spaced in close order like those in the photograph of Hollyhock Palling Belle, but sprinkled. There is a colour that pink sunbonnets go to when they have been much washed, blue-shadowed in an evening light. That is the colour of these hollyhocks: pale violet rose shining against the greenish blue of windless evening sky. Readers of Mr. Stephen Graham may remember his picture of yellow hollyhocks growing like this by the northern shore of the Black Sea. Those, I suppose, were Althæa ficifolia, while this Greek one was A. rosea, a parent of the garden forms.

A correspondent in this column, writing the other day in praise of the series of flower colours called magenta, was asking for a hollyhock of suitable colour. Would the species do? If so, I shall be pleased to send seed to her or to anyone else who cares to try it. The seed has at least the merit of coming straight from the wild source, where the plants are unweakened by the rust of gardens. If you only want the massive columns of a Palling Belle, do not bother about this wilding. But in a wildish place, or where Lavatera Olbia grows with Salvia nemorosa and silver artemisias, it may be worth trying.

Another fine sight has been Vitex Agnus-castus. As it grows here, in great bushes of lavender blue or pink-flushed white, it looks very unlike the plant one knows neatly trained on walls at home (*e.g.*, at Kew). It thrives in the sandy alluvial soil of the river bed, making clouds of colour 8ft. or 10ft. high and 4yds. or 5yds. through. In its wild state the plant is extremely variable, some bushes having short spikes, others long plumes reminding one of buddleia, some a strong blue, deeper in tone, I should say, than Ceanothus Gloire de Versailles, others in the equivocal grey-blue that is so beautiful in Ceanothus thyrsiflorus griseus, and others again in white with rosy buds. I kept thinking as I walked through the groves of them how well they would carry the trails of clematis. Just as Ceanothus Gloire de Versailles is an ideal companion for the bluer clematises, such as Perle d'Azur and Jackmanni, so would the bluer types of vitex be. The paler vitex should carry, say, Jackmanni superba or Gipsy Queen or Lady Betty Balfour, and the rosy white should be the foil for Ville de Lyon or Kermesina or that splendid Crimson King.

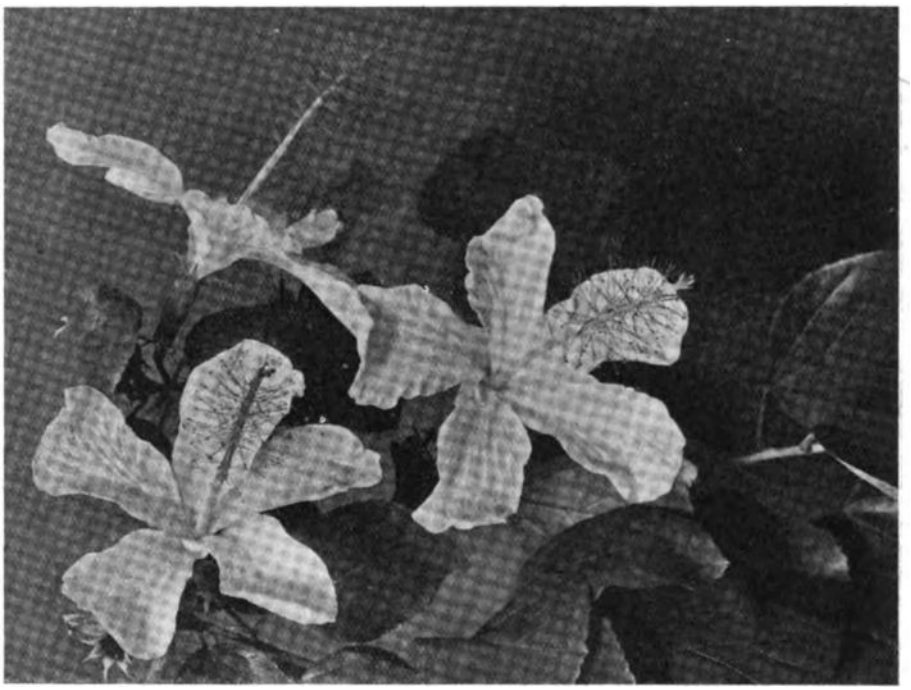
To be able to grow oleander really well out of doors is one of the chief opportunities of gardening in a climate rather hotter in summer than ours. Here the wild pink sort bursts out of cliff faces or spreads on the river shingles and among the olives by the roadside, and it seems equally at home and in place in a garden mixed up in a forest of self-sown hollyhocks or in a tub on a Venetian balcony. (Would anyone care for wild seed of this?) Here are a few of the characteristic summer flowers of the neighbourhood: Cistuses (pink and white), Clematis Flammula, Spartium junceum, myrtle in great beauty and profusion, Erica arborea and E. stricta (?), Arbutus Unedo and Andrachne (?), white rose (sempervirens?), acanthus, the dreadful crimson-spotted arum that reeks of carrion, and the magenta gladiolus. In winter there are the cyclamens. Even now one can occasionally see their huge bulbs sticking out of a weathered bank like knobs of wood, and in their flowering-time they must be almost as lovely a sight as the Anemone blanda. The common eryngium (tripartitum, or one like it) that fringes every road makes a haze of perfectly related blue against the straw yellows of burnt fields, and one begins playing again the game of finding the perfect complement to eryngium blue. In a border with E. Oliverianum and planum and tripartitum (to go no further) there are inexhaustible opportunities. Try, for instance putting a montbretia of middle orange yellow tone, such as George Davison, with E. Oliverianum, or Alstrœmeria aurantiaca major, or Lilium pseudo-tigrinum, or mulleins and pale yellow potentilla. The violet Eryngium Violetta is also delightful to play about with. Try it near Sparks' dark purple aconite and Thalictum dipterocarpum.

Besides the wayside eryngium there is an intense vivid blue one that makes low rounded bushes on the flats near the sea, far the bluest eryngium I ever saw. And there is an intensely blue echinops, dwarfer than humilis and perhaps even bluer. These blue flowers leap to one's eye in this sunlit country, especially where the fields are all burnt tawny or yellow. Not that sunlight is the best light for all of them. The vitex never shows up properly till the light is getting low or shadow falls on it, and the same is true of the bluer rhododendrons, such as Augustinii and hippophæoides and of many magenta flowers too, such as the magenta phloxes.

I have seen some welcome rock plants here: Campanula lanata flattened out on shady cliffs holding up big Canterbury bells in a luminous campanula blue; another smaller campanula in similar places with flowers rather like those of a C. garganica: a pinguicula that is gregarious growing in hundreds close together on wet, mossy rocks and having large conspicuous pale flowers. And, lastly, I will mention the caper flower. Have you ever seen the capers on the Acropolis? Long grey-green trails of leaves beautifully graduated in size and buds that flatten till they burst open into great white St. John's worts, or eucryphias, with violet anthers. On the Acropolis they trail about among fallen chunks of the honey-coloured marble, and sometimes, looking down from the ramparts of an Italian hill town, one can see a caper hanging out of the wall below. That is why boiled mutton brings to mind the Tuscan plain and on the Acropolis one remembers the boiled mutton. —A PAINTER.

HIBISCUS WAIMEÆ.

THIS hibiscus, which received an award of merit at the R.H.S. meeting on September 9th, is without doubt one of the most beautiful species of the genus. It is a native of the Hawaiian Islands, where it forms a small tree up to 25ft. high. The plant was obtained for Kew from a Californian nurseryman under the name of H. Arnottianus, and it first flowered in the Mexican House in 1913. Planted in a border of this house the plant is now about 12ft. high, and on account of its free-blooming disposition and the remarkable size of the flowers it is much admired by visitors during August and September. The large white flowers, from 6ins. to 8ins. in diameter, with the conspicuous reddish coloured staminal column over 6ins. long, are most attractive. When not in flower the plant is very ornamental with its large, sub-orbicular evergreen leaves. H. Waimeæ is quite suitable for the warm greenhouse, and although it thrives best when planted in a border, it may be successfully cultivated in a large pot. It requires similar treatment to the well known H. rosa-sinensis, the group to which it belongs.—T. W. T.



THE LARGE WHITE FLOWERS OF THE HAWAIIAN HIBISCUS WAIMEÆ.

FORTHCOMING EVENTS.

November 11.—Brighton, Hove and Sussex Horticultural Society's Exhibition (three days).

November 13.—The Sheffield Chrysanthemum Society's Annual Show (three days).

SIMPLE GARDENING

PLANTING ARABIS, AUBRIETIAS, AND DAISIES.

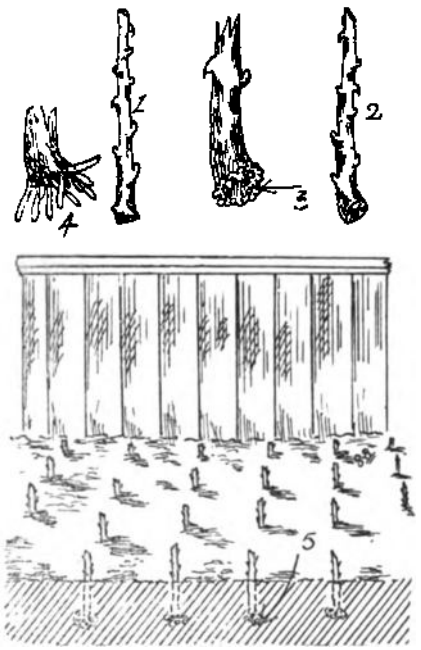
OLD plants are never as satisfactory as young ones, and the latter, if well treated, bear wonderfully fine individual flowers. Usually, too, these and similar kinds of plants are grown in a very poor soil which has the effect of spoiling the foliage as well as the blooms. Rows of the double-flowered arabis have borne spikes of flowers resembling from a short distance those of hyacinths. Of course, to obtain these lovely flowers the plants should be properly cared for early in the season—directly the flowering stage is passed. We have, now, to deal with the planting of the specimens in the borders where they are to flower. Both the arabis and aubrietia will succeed in a medium light loam; indeed, I have grown them in almost pure sand. They thrive, too, in a rather heavy loam if planted carefully when the soil is rather dry. The daisies like a stiff loam better than a very light or sandy one. In the former, organic manures are not required, and this is a great advantage to town and suburban cultivators. Where the soil is really very light or sandy add rotted manure freely, and always take the precaution to keep the centre of the plant free from soil, as it retards growth. The daisies are suitable as a groundwork, as edgings or bordering plants; but the others are most attractive when seen in clumps, especially the aubrietia clustering and nestling gracefully among other rock plants.

HEDGES.

A well kept garden hedge is like a suitable frame to a charming picture; it is attractive and adds to the beautiful features that a nicely appointed garden contains. Three times every year the hedges need attention, mainly to keep them free from rank weeds and straggling shoots. The principal times are May (for evergreen plants), midsummer, September and late in October. However carefully done in September, some straggling shoots will grow after the cutting then. These shoots should be dealt with now whether they are on evergreen or deciduous plants. This is also a suitable date for soil cleaning under hedges. In doing this work, however, refrain from unduly cutting off basal shoots, as it would entirely spoil the general appearance of the fence. The sides should be full and shapely right down to the soil, giving a pyramidal form to the hedge and not that of a balloon. Rank and tap-rooted weeds get established in the soil around the roots of young hedge plants, and when this occurs through want of timely attention it is a difficult task to remove them. All young hedges should be carefully examined during this month for such weeds, which if found, should be taken up with tap-roots intact in order to save future trouble. This is also a suitable time to apply a surface mulch of half-rotted manure to hedges that are not as vigorous as they should be.

PROPAGATING ROSES FROM CUTTINGS.

The rose-lover possesses a single plant or, maybe, two or three; the variety is a favourite and he wishes to add to the number. This he may do by taking a few cuttings and inserting them in a cool border—one facing north, north-west or north-east. The most suitable wood is that made during the current year with a "heel," a small portion of old wood attached. But well ripened shoots may be cut off just below a joint, inserted and they root freely. Such is shown at No. 1. No. 2 represents a cutting with a "heel" of older wood attached. No. 3 shows how new roots begin to form—the swellings are termed a callus. Then real roots grow as



shown at No. 4. The cuttings should be about 7ins. long; 4ins. being inserted in the shallow trench at a distance of 6ins. apart. Sand freely scattered in the trench so that the base of each cutting may rest upon it, as shown at No. 5, encourages the early formation of roots and preserves the cuttings from decay at the base. After frosts, when the soil has dried, it should be made firm again by treading.

STORING GLADIOLI CORMS, TUBERS OF BEGONIAS AND ACHIMENES.

Towards the end of this month gladioli corms may be lifted from heavy soils and stored. In light ground they may be left a fortnight later. If the flower-stems were left uncut or others were so cut as to leave plenty of stem and leaves, so much the better. Do not pull up the corms forcibly, but insert the garden fork and gently but firmly raise both soil and corm. Then place the latter with tops and any small quantity of soil adhering to the roots in boxes about 7ins. deep, taking care not to overcrowd them and keep them so for several weeks in a cool, airy, dry shed. In due course the tops and soil can be removed, leaving the corms nicely browned, firm and in good condition for storing in paper bags, which may be kept in drawers or suspended from nails in a dry store-room. The names of the varieties should be written on the bags. The tubers of begonias should be left in the pots or boxes till the leaf-stems naturally fall away, then remove the soil without bruising the skin of the tuber and pack them rather closely together on a thin layer of coconut fibre in a shallow box, filling up the spaces with the same material or dry leaf-soil. These will keep safely in a warm greenhouse. Achimenes are much better retained in their own dry soil in the pots till next spring.

CLIMBING PLANTS IN THE GREENHOUSE.

These plants, when well looked after, always adorn a greenhouse if they are suitable for the structure. Now, by suitable specimens I mean those that will appear to be a part of the house, namely, pillar plants for low and roof plants for lofty houses. If the roof climbers were trained in a low structure they would dwarf it and their natural beauty would be lost. A few pillar plants, neatly trained, would look well in a low greenhouse and would also be suitable for a high one. Borders near back walls in lean-to houses are frequently cold and bad for the roots of plants. Large pots are much more suitable. Front borders are not detrimental. Very sound drainage should be provided in every case and pillars painted before the branches are trained on them to avoid unnecessary disturbance of the plants for several years. The best compost for general use is one made up of very fibrous loam two-thirds, half-rotted leaf-soil one-third, and to each bushel of the combined parts a 6in. potful each of coarse sand and old lime rubble. Feeding can always be attended to afterwards. The following are a few charming climbers or suitable pillar plants. Bougainvillea speciosa, Clematis indivisa lobata, Clianthus puniceus, Cobæa scandens, Ficus repens, heliotrope, Jasminum grandiflorum, Passiflora Constance Elliott, Plumbago, Solanum jasminoides, tacsonias and tropæolums.

MUSHROOM BEDS.

Hundreds of amateur gardeners make the attempt to grow mushrooms and fail because they neglect to attend to minor details connected with their cultivation. If it is the first attempt this should be made in the autumn, or even in mid-winter, rather than in the summer-time, because it is easier to manage the beds correctly in cold than hot weather, providing sheds and other necessary materials are available. A very suitable position, also, is one under the stage in a greenhouse. Beds formed and spawned now will bear mushrooms in February and March.

GEORGE GARNER.

Digitized by Google

GARDENING OF THE MONTH

FLOWER GARDEN.

ANTIRRHINUMS.—Sow on light soil in frames and plant out in spring.

BORDER CARNATIONS.—Pot remaining layers which have not been planted out and stand in frames for the winter.

BULBS.—Plant the remainder as soon as possible. Prepare ground well, add wood ashes and bone-meal and a little sand at the base of bulb, and plant fairly deeply. Make flat-bottomed holes.

CALCEOLARIAS AND PERENNIAL LOBELIA.—Lift, put roots in light leaf-soil, and store in a frost-proof house. Keep soil slightly damp.

EARLY CHRYSANTHEMUMS.—Lift and store roots in a cold frame.

HERBACEOUS BORDERS.—Finish the planting and reconstruction at once. Divide and re-arrange large clumps of perennials. Do not disturb anchusa, delphiniums, lupins or tritomas. Double dig the borders, giving a liberal supply of manure and a good dressing of lime. Basic slag at the rate of 4 oz. per square yard may also be added. Keep tidy and tie up remaining plants.

LILY OF THE VALLEY.—Plant crowns in well prepared beds of good loam and leaf-soil. Make beds in partial shade facing west.

PROTECTION.—Place bracken or ashes over the roots of pyrethrums, scabious and gaillardias. Cover helleborus with lights supported on boards.

ROSES.—Chief planting time. Double dig ground and allow to settle. Manure well, but do not allow manure to come in contact with roots. Add basic slag at the rate of 6 oz. per square yard. Plant firmly. Prune, cut out old wood and tie up climbers and ramblers.

SPRING BEDDING.—Finish planting out at once.

STORE begonias, cannas, dahlias, gladioli and Hyacinthus candicans. Lift and place in a frost-proof shed.

FRAMES.—Ventilate carefully all cuttings. Stir soil frequently; prevent damping, and pick off decayed leaves. Examine rock plants in pots plunged in ashes.

VEGETABLES.

ASPARAGUS.—Cut down grass to within 6ins. of the ground. Clean beds and top-dress with well decayed farm manure.

BROCCOLI.—Protect by taking out a spadeful of soil on the north side of plants, bend the heads to face north, and place removed soil over the stems.

BROAD BEANS.—Sow early dwarf or long-pod varieties on a warm south border.

CELERY.—Complete final earthing up. Draw soil carefully round the head until only the tips of the leaves are visible.

ENDIVE.—Lift some plants carefully and replant in a cold frame. Cover with dry leaves for blanching. Ventilate only on sunny days.

PARSNIPS.—Lift and store these if obliged, but they are best left in the ground.

PEAS.—Sow round-seeded varieties fairly thickly on a warm border.

SEAKALE.—Clean beds. Lightly fork in from 3lb. to 4lb. of kainit per 30 sq. yds. Place 9in. pots over each crown, cover the whole area with leaves, with a little manure on top.

ROOT CROPS.—Store beet, carrots, celeriac and salsafy in a frost-proof shed. Sprinkle sand between each layer.

GENERAL.—Trench ground where root crops have been grown ready for onions, cauliflower and early broccoli next year. Add well decayed manure at the rate of a cartload per 4 or 5 sq. rods. Double dig other vacant land, giving a smaller dressing of manure and basic slag at the rate of 7lb. per sq. rod. Give all land a dressing of quicklime, using 3 bushels per sq. rod. Apply gas-lime to ground infected with pests, such as cabbage gall weevil, club-root, etc., letting it remain on the surface until spring.

HARDY FRUIT.

PLANTING.—Hardy fruit, including bush fruit, should be planted as soon as possible. Prepare ground well and allow to settle. Give a dressing of lime for stone fruit. On heavy soils plant on a slight mound. Cut away bruised portions of the roots, using an upward cut. Do not plant deeply; spread out roots, press soil in between, avoiding "air pockets." Stake securely. In cold districts protect with a light covering of litter.

PRUNING.—Can be done any time from now onwards. Cut out old fruiting wood and lay in young wood of peaches, nectarines and Morello cherries, and nail up again to the walls. Cut old fruiting wood from raspberries and loganberries, and tie the current year's wood to the wires.

PROPAGATION.—Insert cuttings of gooseberries and currants.

PESTS AND DISEASES.—Burn black currants infected with big bud; do not plant in the same position for several years. Remove top 3ins. of soil under gooseberry bushes attacked by sawfly and burn the soil. Cut out parts infected with canker and dress wounds with gas tar.

CLEARING.—Clear off weeds round bushes and trees after pruning, and lightly fork in between.

ROOT PRUNING.—Trees which have made excessive growth and are unfruitful need root pruning. Lift young trees, cut back the tap roots and replant. Root prune others where they stand by taking out a trench 3–5ft. away from the base of the tree and digging down to the roots. Cut away roots penetrating the soil perpendicularly, and fill in the trench with fresh compost.

INSIDE FLOWERS.

ANNUALS.—Pot on in sandy compost for flowering in spring. Guard against damping. Stake well and keep the temperature 45°–50° at night.

ARUMS.—Will stand considerable forcing if necessary. Give plenty of moisture if temperature is high. Give frequent doses of liquid manure, soot water or Clay's fertiliser.

BEGONIAS.—Stake carefully, keep temperature 55°–60° at night.

BULBS.—Bring in Roman hyacinths and Paper White narcissus in batches from the "plunging ground." Do not expose fully to light for the first few days.

CALCEOLARIAS AND CINERARIAS.—Pot on into 5in. pots. Cool conditions are necessary. Never allow cold draughts to blow on cinerarias or let them become "pot-bound."

CARNATIONS.—Ventilate freely, always keep a crack of air on. Syringe occasionally to keep down red spider. Maintain a night temperature of 55°.

CHRYSANTHEMUMS.—Give a free circulation of warm dry air to prevent damping of blooms. Insert cuttings in sand, using basal growths only.

LILIUMS.—Keep L. longiflorum growing well and in a temperature of 45° at night. Fumigate regularly for aphis.

PRIMULAS.—As they come into flower keep atmosphere dry; only water when necessary and maintain a temperature of 45°–50° at night.

SHRUBS.—Wash cool-house with insecticide; bring in pot shrubs from outside. Keep azalea and camellia roots moist to prevent bud-dropping in spring.

ZONAL PELARGONIUMS.—Pot autumn-struck cuttings into 4in. pots. Give spring-struck cuttings a drier atmosphere as they come into flower. Ventilate well and keep the temperature 50°–55° at night.

SHRUBS AND TREES.

PLANTING.—With few exceptions, plant now.

PRUNING.—Cut back shrubs which flower on the young wood made during the current summer. These include Ceanothus azureus C. Gloire de Versailles, spiræa, Buddleia variabilis, Hydrangea paniculata, Jasminum officinale, etc. Cut back straggling growths of Buddleia globosa, berberis, choisya, rhododendrons, etc. Nail long growths of climbers to the walls.

HEDGES.—Plant holly, yew, hornbeam, Rosa rugosa, Penzance briars, Cupressus Lawsoniana, etc. Trim conifer hedges.

TRANSPLANTING.—Remove shrubs and trees more than three years old with a ball of soil attached. Transfer intact by wrapping round with sacking. Preserve all fibrous roots, especially of evergreens.

GENERAL WORK.

LAWNS.—Finish patching and re-turfing. Drain wet lawns, treat with worm-killer if necessary. Rake with an iron rake, apply lawn sand to help to destroy fibrous-rooted weeds and moss. Top-dress and feed lawns.

WALKS.—Roll and apply weed-killer.

LEAVES.—Collect, tread firmly and scatter slaked lime between each layer. Store wood ashes in a dry shed.

ROCK GARDEN.

Generally clear up and tidy for the winter. Pick off dead leaves and flower spikes. Stir the surface of the soil.

TOP-DRESS.—Give a top-dressing according to the requirements of the plants. Use a gritty compost made from finely crushed limestone except for "lime-haters," *e.g.*, Campanula alpestris, Achillea ageratifolia, erica, gentiana, silene, etc. Give more grit to some plants, *e.g.*, androsaces; and daphne, lithospermum, etc., a peaty compost.

PROTECTION.—Lodge a piece of glass over some plants, especially those with hairy leaves and those which suffer by remaining wet in the centre.

INSIDE FRUITS AND VEGETABLES.

FIGS.—Prune, wash trees and houses with Gishurst's compound. Remove top few inches of soil, top-dress with good loam and little bone-meal. Ventilate freely.

NECTARINES AND PEACHES.—Treat as for figs, taking care not to rub off the buds when washing. Do not allow the borders to become dry, otherwise the buds will drop in spring.

VINES.—Examine and pick off decaying berries from branches of late vines. Cut soon and store in bottles, then ventilate freely. Prune mid-season vines. Scrape off bark and wash with Gishurst's compound. Clean the houses. Paint with methylated spirit any parts infected by mealy bug. Keep vines on the dry side. Extend or re-make borders if necessary.

CUCUMBERS.—Keep temperature 65°–70° at night. Syringe lightly. Top-dress mounds when roots appear, and keep atmosphere humid.

RHUBARB AND ASPARAGUS.—Lift and force roots in boxes under the staging.

BOOK REVIEWS

A COMPANION volume to Mr. Dykes' recent publication on "Garden Irises" has just come to hand in the form of "A Handbook of Crocus and Colchicum for Gardeners," by E. A. Bowles (Martin, Hopkinson and Co., Limited, London, 12s. 6d). The genus crocus is one which has grown enormously of late, and it has been well-nigh impossible to all save specialists in the flower to acquire an up-to-date and working knowledge of the many species and varieties which go to make the crocus one of the most interesting of our time-honoured flowers. This work, by one of the acknowledged authorities on the genus, comes at an opportune time, serving a most useful purpose by presenting in an interesting fashion a great mass of valuable historical, topographical and cultural information. After an extremely useful glossary of botanical terms, which all gardeners should find helpful, the author goes straight ahead to discuss the merits of the crocus as a garden flower. Many helpful hints are given to obtain the best results, and these are all the more valuable as they are the combined results of some thirty years' experience with the plant. The second chapter is a most instructive one, and therein the writer proves himself to be a botanist of no mean repute. The characters of the flower are singled out individually and dealt with at length in an extremely lucid manner. At the end of this chapter is a most interesting paragraph on the probable origin and distribution of the genus. From well reasoned argument he arrives at a "Southern or possibly North African origin and Romulea as a probable ancestor." The next ten chapters are devoted to descriptions of the various groups and the species comprising them. Each species is clearly and precisely described, peculiarities and any other outstanding characters noted. For example, when dealing with the Saffron crocus an exceedingly interesting *résumé* of the drug is given, which brings relief to the reader who has been wandering through descriptions of species. The specific descriptions are everything they should be, giving authorities, collector's name, region where found, colour and references to literature. A useful bibliography of the crocus completes that section of the book extending from 1597 to 1886. The last six, or more correctly five, chapters are given over to colchicum, wherein the author points out the clear distinctions which exist between the two closely related genera. This genus is treated on the same lines as those dealing with crocus, and the last chapter appears to be a helpful inclusion dealing with two plants which are frequently confused with colchicums, viz., bulbocodium and merendera. An index of undoubted assistance brings a most delightful book to a close. The illustrations throughout are admirable, and show every care in execution.

To the practical gardener and the botanist alike this volume should prove of the greatest interest and assistance. It contains a great amount of information which is treated in a lucid and captivating yet instructive style. The undoubted value of personal experience is worth much in such a practical manual, as it ensures that the reader will not readily find himself in the many pitfalls which entrapped the author in his cultivation of these two genera. The book is excellently printed throughout and is one which shows every care in compilation and proof reading. G. C. T.

THE newcomer to the gardening world is rather apt, these days, to be overwhelmed by the sea of literature which awaits him after embarking on his course, and, unfortunately, he is all too often wrecked in the sweeping and surging tide of information which confronts him in the various manuals on this subject. Such is to be deprecated, and the need of some simple, almost what one might term home-made, gardening recipes has long been felt. Such are to be found in the present little book, aptly called "A Real A.B.C. of Gardening," by A. J. Macself (Thornton Butterworth, Limited, London, W.C.2., price 6s.). As the author remarks in his preface, he begins at the starting point, catering for the "fresher" page by page. The manual gains much in value by being divided up into four parts—the first dealing with general or elementary principles, the second with planting and seed sowing, the third with seasonal work, while the fourth concerns itself with various phases of gardening work, such as manures, propagation, etc.

Many useful, timely hints and suggestions are given throughout its pages which should prove invaluable to the uninitiated. Tables listing hardy perennials for town gardens, shady situations, etc., vegetables for sowing, garden herbs, bulbs and tubers, are to be found and these, giving information in a concise and easily understood manner, are to be recommended. Mr. Macself's style is simple, lucid, yet decidedly instructive throughout the book, which can be recommended to the amateur as a useful and handy guide in his wanderings in the dark in a world where many unforeseen difficulties are apt to crop up, making one almost despair of success at times. It does not aim at being a comprehensive volume on the subject, but, as its title implies, is merely an introduction or A.B.C.

DURING the last twenty to twenty-five years our cousins across the "herring-pond" have imbibed deeply of all the available gardening knowledge in this country, and it is indeed interesting now to witness the first fruits of that knowledge in the shape of the book which lies before us, "Adventures in my Garden and Rock Garden," by Louise Beebe Wilder (Doubleday, Page and Co., New York, 5 dols.). The title is one which gives little idea as to the contents of the volume, as, after all, how many of us do have adventures in our gardens—unless it be one of a kind so different from those of our schooldays. A garden is surely not a place wherein one goes to seek adventure, but rather should it be looked upon as a sanctuary or haven. Be that as it may, one has all the greater joy in perusing its pages to discover these so-called adventures—the raising of a representative collection of American plants, and a comparison of the results obtained in the garden with those of the plants in their native habitat, a most interesting and engrossing occupation, no one will deny, and one which never fails to bring out new points of great cultural value. Plant associations in a garden hold much the same regard for the amateur as plant ecology does for the scientist, and if one has a knowledge of the latter it serves as a valuable guide to the former. In the author's garden one recognises plants from all the four corners of the globe, and they all appear to enjoy the association of their newly found neighbours. One claim of the author which calls for special mention is the fact that continuous bloom for eleven months out of twelve has been obtained. Again, the book abounds in personal experiences with many plants, which in itself is a valuable guide to growers in the States. For the more serious-minded, useful tables of shrubs and annuals for the rock garden are to be found in the two concluding chapters, while an exceedingly helpful appendix extending over ninety-two pages contains personal notes and observations taken over a period of some fifteen years in two gardens "differing considerably as to soil, climate and altitude." A good point mentioned is that all plants in the list are obtainable from nurserymen in America. The appendix shows every care in compilation and is well worthy of attention. Another appendix, giving plants for special purposes, should also prove of great assistance to a beginner who wishes success to attend his efforts and who is in quest of some desired effect. Chapters on soil, bulbs, seeds and landscape effects should prove as helpful to "the old hand" as to the amateur. A complete index brings one to the end of this interesting and useful manual. It is written in a captivating though somewhat American style, but the book loses nothing in lucid and clear expression. It is excellently printed, and illustrated by means of half-tone blocks. It is a book which an amateur, whatever his speciality, would find both interesting and instructive, although, unfortunately, it is not within the reach of everyone.

THE SWEET PEA AND ITS CULTIVATION, by W. J. Unwin, Histon, Cambridge. 1924. and Supplement, 1925.

THIS is an exceedingly useful little booklet on the sweet pea by Mr. W. J. Unwin, whom no doubt many of our readers have heard on the wireless in his sweet pea talks. In it the author has written interesting chapters on historical notes, cultivation for exhibition, culture for ordinary purposes, diseases and pests, and notes on varieties. It can be well recommended as a concise and informative little booklet.

PUBLICATION RECEIVED.

"The Bungalow Book," by Charles E. White, jun. Published by The Macmillan Company, New York. Price $2.25.

CATALOGUES RECEIVED.

Morse Brothers, Melton, Woodbridge, Suffolk.—Roses.

E. P. Dixon and Sons, Limited, Seed Merchants, Hull.—Fruit Trees, Roses, Herbaceous Plants.

Blackmore and Langdon, Bath.—Begonias, Delphiniums, Gloxinias.

D. and W. Croll, 63, Commercial Street, Dundee.—Bulbs.

Lowe and Gibson, Crawley Down, Sussex.—Border Carnations and Bearded Irises.

A. and W. Perry, Hardy Plant Nurseries, Enfield.—Comprehensive list of hardy plants, including alpines, ferns, rare shrubs, etc.

Reginald Winder (formerly Winder and Thomson), Lingwood Lodge, near Norwich.—Roses, Shrubs, Garden Planning, etc.

R. W. Proctor and Sons, Ashgate Road Nurseries, Chesterfield.—Roses, Bulbs and Sundries.

W. J. Unwin, F.R.H.S., Histon, Cambs.—Sweet Peas, Bulbs and Roses.

Laxton Brothers, Bedford.—Fruit Trees and Small Fruits, with many Novelties.

Thomas Rivers and Son, Limited, Sawbridgeworth.—Fruit Trees, Roses, Shrubs and Hardy Perennials.

FOREIGN.

F. Delaunay, Angers.—Trees and Shrubs and Fruit Trees.

Messrs. Rivoire and Sons, 16, Rue d'Algerie, Lyon, France.—Flower and Vegetable Seeds.

SPECIAL AUTUMN OFFER

50 Spanish Iris, in lovely colours, given free with every order of 20/-, 100 with £2 orders, etc.

A FEW CHOICE SHRUBS FOR EARLY PLANTING.

Rhododendrons (named), all colours, 3/- and 3/6 each. 5,000 **Clematis**, Jackmanii, Woking Belle, Gipsy Queen, Montana (white and pink), Duchess of Edinburgh, 2/6 each, 24/- doz. **Lavender** (Old English) and Cotton Lavender, 6d. and 9d. each (fine for edging). **Flowering Cherry** (Bush), 3/6 and 4/-. **Bush Lilac**, red or white, 9d. each. **Buddleia Variabilis** 3/6 each. **Yellow Broom**, 3/6 each (large plants, 3-4 ft.). **Veronica**, 6d. and 9d. each. **Euonymus**, golden and green, 6d. and 9d. **Snowberry**, 6d. each, 4/6 doz. **Southernwood**, 6d. **Ribes** (flowering Currant), 9d. and 1/-. **Golden Elder**, 6d. and 9d. **Hydrangea Paniculata**, 1/- each. **Scarlet Willow**, 6d. **Honeysuckle** (Scented variety), 2/-. **Wisteria**, (Mauve), 2/6 each. **Prunus Triloba**, lovely pink early-flowering shrub, 3/6. **Cotoneaster** 1/-. **Bamboos**, 1/-, fine clumps. **Genista** (Broom), fine colours, named varieties, 2/-. **Mountain Ash** (young standards), 1/- each. **Magnolia**, 4-5 ft., a few specimens only, 7/6.

Bulb Collections to suit all buyers. *All guaranteed first-class quality.*

25	**Large Hyacinths** for bowls or glasses, named colours	5/6
25	**Bedding Hyacinths**, 5 colours	3/6
100	**Early Tulips**, 5 colours	7/-
100	**Double Tulips**, 5 varieties	7/6
100	**Darwin Tulips**	7/6
100	**Mixed Bulbs** (Daffodils, Hyacinths, Tulips, Snowdrops, Crocus, etc.)	4/6
100	**Scented Daffodils** and Narcissus (10 favourite varieties, named)	8/6

All Carriage Paid.
Thousands of others to offer—Send for List.

20,000 SPLENDID ENGLISH FRUIT TREES

Standards, fine tall specimens, 6/6 and 7/6 each.
Apples, Pears, Plums, Cherries (Bush and Cordon) 2 to 3 years at 2/6 and 3/- each; 3 to 4 years, 3/6 and 4/- each.
Splendid specimens, 5 years, at 5/6 each.
Special Cordon Pears, 2 to 3 years.
Fertility.—These trees, standing 3 to 4ft. high, have now 20-30 Pears on every specimen. You must grow these. Order early as stock is limited.
Apples.—Cox's Orange, Bramley's, Worcester Pearmain, Lane's Prince Albert, Stirling Castle, Warner's King, Ellison's Orange, King Pippin, James Grieve, etc.
Pears.—A splendid lot. William's, Fertility, Buerre Superfine, Jargonelle, Clapp's Favourite, Marie Louise, Pitmaston Duchess.
Plums.—Victoria, Belle de Louvain, Pond's Seedling Greengage, etc. All fine trees.
Cherries.—Gov. Wood, White Heart, Black Heart, Elton's Early, Biggareau, etc.
Red and Black Currants.—3/6, 4/6 and 6/- doz.
Raspberries, 1/6 doz. **Strawberries**, 5/- 100.
Loganberries, 9d., 1/- and 1/6 each.
Hallshamberries, 4/6 and 6/- doz.
Rhubarb.—Daw's Early, Ruby, Champagne, 9d. and 6d. per root.

SPECIAL OFFER ENGLISH STANDARD ROSES

For early orders only 2/6 each.
Daily Mail, Sunburst, Rayon d'Or, C. Testout, Killarney, Ophelia, G. Dickson, McArthur, Edu Meyer, Radiance, Red Star, Capt. Haywood, Lady Ashtown, Jules Grolez, Progres, J. Laing, Prince de Bulgarie, Ravary, etc., etc. All fine strong trees, and have now a good show of bloom.
Bulbs carriage paid.
Bush Roses, same varieties, 10/6 doz.

Hedge Plants.—Evergreen Privet, 3ft., £2 per 100; 1½ to 2ft., 35/- per 100; 12ins., 20/- per 100. Common Privet, 2 to 3ft., 17/6 per 100. Quick, 1½ to 2ft., 20/- per 100.
Vines.—Black Hambro, 3/6 and 4/6 each.
Walnuts.—2/6 each.
Filbert and Kentish Cob Nuts.—2/6 each.

PERENNIAL PLANTS FOR EARLY PLANTING

Wallflowers, red, golden, crimson, yellow, 4 vars., 2/6 per 100, carriage paid. Fine Bushes, transplanted, 1/- per doz. **Pansies**, Giant French, 9d. per doz. **Violas**, 2/- per doz., mauve, yellow, purple. 3 **Hollyhocks**, 6d. 2 **Anchusas**, 6d. 4 **Arabis**, double white, 6d. 2 **Lupins**, 6d. 3 **Polyanthus**, 6d. 6 **Forget-me-Not**, 6d. 2 **Oeum** Mrs. Bradshaw, 6d. 4 **Sweet Williams**, 6d. **Pampas Grass**, large clumps, 1/- and 1/6 each. **Pinks**, Mrs. Sinkins and Her Majesty, 2/- doz. **Iceland Poppies**, 1/- doz. **Carnations**, mixed, 2/- doz. **Christmas Roses**, 1/- and 1/6 each. **Lovely Phlox**, named, all colours, 12 for 7/6. **Iris Germanica**, 2/6 doz. **Iris Kaempferi**, 5/6 doz.

HERBS

Sage, 6d. and 9d. **Thyme**, 6 for 6d. **Mint**, 6 for 6d.
Passion Flowers.—Blue and white, 1/6 each.
Lovely Pyrethrum.—Queen Mary, J. Kelway and Cerise Pink, 5/- doz.
Montbretia, 5/- 100. **Spanish Iris**, 5/- 100.
Tree Carnations.—Perpetual flowering, named, blooms, 2-3 ins. across. Splendid for potting up for cool greenhouse, will bloom continuously from Nov. to June, 1/- each, 10/6 doz.
Rock Plants, in about 12 varieties, 2/6 doz., named.
50 Cabbage Plants 6d. **50 Onions** 6d.

Please give Name and Address (Post and Rail).

All Trees and Plants sent as soon as ready. *Kindly add extra carriage for Trees and Plants.* *All orders over 20/- carriage paid.*

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Gilia coronopifolia (J. P.).—It is not safe to trust this plant outdoors during the winter, although it will often stand in warm dry soils. In common with many Californian plants of this class, damp during the winter months often proves fatal. Your plants should be quite safe in an unheated greenhouse. They should be given a light sunny position, and are best kept on the dry side, giving them no more water at the root than is necessary to keep them from suffering. The foliage should also be kept dry.

THE GREENHOUSE.

Unheated Vinery (C. B., Tetbury).—Do not be tempted to install stoves, lamps or heaters of any "makeshift" description; such contrivances, instead of providing an efficient remedy for the present evil, will bring in their train further and probably greater troubles. Predisposing causes of mildew are stagnant moisture, cutting draughts and erratic ventilation. If there is a bed of old, sour soil in the greenhouse, or even an earth path that becomes soddened with moisture, it will be an immense benefit to remove several inches in depth of the soil, and replace with coarse clinkers, stones or brick rubble, finishing off with ashes. See that walls, rafters, stages and doors are well cleaned, using hot water, carbolic soft-soap and a stiff scrubbing-brush, especially where there happens to be any green slime or other discoloration. Limewash brickwork after scrubbing. Next scrub the branches of the vines with a hot solution of Gishurst Compound—directions for preparing this are supplied with each package, obtainable from seed merchants, etc. The foregoing general cleaning should be carried out in full now, as the spores of mildew will be dormant about the vines and the house through winter. With a clean start, the vines may be kept healthy and clean next season by keeping the house well ventilated, but exercising care to prevent cutting draughts. Do not be impatient to hasten the vines into activity too early by keeping the house too close. Use ordinary flowers of sulphur freely, distributing with a powder bellows, dusting rods and foliage as well as stages and pathways. Dry sulphur is the deadly enemy of mildew. Encourage healthy growth of the vines by applying a good fertiliser to the borders, and your vines should fully recover their cropping powers. Half the trouble with unheated vineries is caused through endeavours to secure high temperature by keeping the house tightly closed, the result being violent changes from high day temperature to low night temperature.

MISCELLANEOUS.

Treating a Sloping Bank (M. T.).—The bindweed referred to is, no doubt, convolvulus, and its roots should be taken from the soil before any other plants are established there or it would soon become troublesome again. The deep digging necessary to remove these fleshy roots would be beneficial for the following plants, namely: Crocus, narcissi, crown imperials, snowdrops, Scilla sibirica, Anemone japonica, columbine, spiræas, violas, dielytras, saxifragas, doronicums, delphiniums, primroses and campanulas. The roots of privet rob other plants and it would be advisable to take out a trench between the hedge and the border and to keep the privet roots in bounds.

British Florists' Federation. — The British Florists' Federation's Market Floral Committee met in Messrs. Monro's salerooms on Monday, October 20th, at noon. Mr. W. E. Wallace presided and Mr. R. Miller, a florist from Neutra was present as a visitor. The Committee granted a provisional first-class certificate to Chrysanthemum Gloriosa, shown by Mr. H. Shoesmith, Woodbridge Nursery, Guildford. This is a reflexed Japanese variety of good size and pretty, rich, golden-bronze colouring. One of the plants shown carried no fewer than thirteen good blooms on long stems.

Perennial Asters. — The R.H.S. will carry out a trial of perennial asters in its gardens at Wisley during the coming year. Raisers are invited to send three plants of each new variety introduced since the last trial in 1919-20, to reach The Director, R.H.S. Gardens, Wisley, Ripley, Surrey, on or before November 30th, 1924. The necessary entry forms may be obtained on application to him.

Importation of Bulbs into the Isles of Scilly.—The importation of bulbs into the Isles of Scilly has been restricted since January 1st last by the Bulb Diseases (Isles of Scilly) Order of 1923, which requires every consignment of daffodil or narcissus bulbs landed in the Isles to be accompanied by a certificate that they have been examined and found free from disease, or a declaration that they have been submitted to the hot-water treatment. At the request of the growers in the Islands the Ministry has issued an amending Order—The Bulb Diseases (Isles of Scilly) Order of 1924—which came into operation on October 1st. Under this Order, the landing of daffodil and narcissus bulbs in the Scilly Isles may be licensed by an Inspector of the Ministry, on condition that the bulbs are sent direct to the Bulb Treating Station which has been established at St. Mary's by the Agricultural Committee of the Isles of Scilly, and there submitted to the hot-water treatment before being handed over to the actual consignee.

National Sweet Pea Society. — The management of the National Sweet Pea Society has cause for self-congratulation. At the annual general meeting on October 21st, the report and balance sheet showed that an immense improvement had been effected in the condition of the Society during the past year. Twelve months ago, through a variety of causes, there was a serious deficit on the year's working and the prospects did not appear to be at all rosy. But by dint of careful management the deficit has been transformed to a "surplus of over £12," and this, in view of the fact that the valuation of show plants had been marked down considerably, is a good augury for the future. The membership showed a proportionately large increase and, we learn, is the greatest during the present decade. That this enviable condition of improved finance and increased membership was caused largely by the untiring work of the Secretary, was evidently fully realised by the members who unanimously re-elected Mr. A. C. Bartlett to that responsible post. The new President is Mr. Edward Sherwood, while Mr. H. A. Perkin is to be Chairman of Committee and Mr. J. M. Bridgeford continues to be Hon. Treasurer. Considerable interest centred in the proposed alterations to several of the rules which govern the Floral Committee, but when it was fully realised that the Society's annual trials of new sweet peas are as secret as the parliamentary ballot the proposals were thrown out. But we feel that good has come of them inasmuch as they led to an amendment of a rule which provides that the Floral Committee shall be composed equally of amateur and trade experts, with the addition of an amateur as chairman. The trials of novelty sweet peas are again to be grown at the Syon House Gardens, Brentford, and next year's show is to be held at the R.H.S. Hall, Vincent Square, London, on July 16th and 17th.

International Spring Flower Show, Haarlem, 1925.—On July 1st, the site for the show was placed at the disposal of the organising committee. An office building, specially designed and executed for the purpose, was ready for use on the same day. The elaborate ground work has nearly been completed, and the planting of the bulbs was commenced during the first days of September. The exhibits for the open-air show are so numerous that the grounds will be entirely occupied with them. The great hall for the indoor shows will be completed in January. In front of this building a French regular garden is being laid out, in which enormous masses of crocuses, hyacinths, early and late tulips will flower in succession. In the surrounding grounds there will be a large garden in Old Dutch style, containing a selection of the best and newest varieties of bulbs, planted by the members of the Dutch Bulb Exporters' Association. Almost all the local branches of the Dutch Bulb Growers' Society are sending collective exhibits of their members, all forming very important collections of groups. All the known varieties of narcissi will be shown in the garden planted by the Society of Daffodil Growers. Aalsmeer, Boskoop and Naarden will show their best products for spring gardening. The show will be open from March 13th until May 21st, and excursions from various countries are already in preparation now. It is expected that a special steamer will sail from America for tourists to the Holland flower show and bulb fields next year, and, of course, numerous Easter trips will be organised from England, as the flowering period of the hyacinths will probably coincide with Easter time.

THE following awards have been made to dahlias by the Council of the Royal Horticultural Society, after trial at Wisley.

AWARDS OF MERIT.

Single.—Little Jennie and Nanno, sent by Messrs. W. Treseder, Cardiff. *Peony.*—The Rose, sent by Messrs. Velthuys, Holland. *Small-flowered Peony.*—Rosie, Charmer, Norah Bell and Gwynne, sent by Messrs. J. Burrell, Cambridge; Rosie Supreme, sent by Messrs. Jarman and Co., Chard; Sweet, sent by Mr. A. J. Cobb, Reading *Decorative.*—Polar Bear, sent by Mr. E. Beckett, Elstree; Emblem, sent by Messrs. J. Burrell. *Small-flowered Decorative.*—Carine and Thursa, sent by Messrs. J. Burrell. *Camellia.*—Nelly, sent by Mr. H. Carlee, Holland. *Star.*—Haslemere Star and Hindhead Star, sent by Messrs. J. Cheal, Crawley; Reading Star, sent by Mr. A. J. Cobb. *Cactus.*—Joyce Goddard, sent by Messrs. Jarman and Co; Mrs. Forester Paton, sent by Messrs. J. Cheal.

HIGHLY COMMENDED.

Collarette.—Mrs. M. Perry, sent by Messrs. W. Treseder. *Small-flowered Peony.*—Nuffield Priory and Vimy, sent by Messrs. J. Cheal.

THE dates for the examinations in horticulture conducted by the Royal Horticultural Society in 1925 will be as follows:

Written Examinations.—General Examination (Seniors and Juniors), Wednesday, March 25th. School Teachers' Examination (Preliminary and Honours), Saturday, April 4th. National Diploma, May 9th.

Practical Examinations. — Teachers' Honours, Friday, June 19th, and possibly also Thursday, June 18th. National Diploma, Preliminary, June 23rd and 24th; Final June 25th and 26th.

The attention of candidates is drawn to the fact that entries for the Diploma Examination must be received before January 1st, 1925. Copies of the syllabus and entry forms may be obtained by sending a stamped addressed envelope to the Secretary, Royal Horticultural Society, Vincent Square, S.W.1.

SUPPLY and DEMAND

I HAVE mentioned before the question of supply and demand as regards plants. Usually the supply of a plant keeps fairly level with the demand, but occasionally a considerable lapse of time has to take place before the supply can equal the demand when the demand is of sudden growth, or the plant is difficult to propagate. A typical case of the latter is Acer griseum, which was introduced by Wilson in 1901 from Central China through Messrs. Veitch of Chelsea. Now, for some reason or another Messrs. Veitch rarely produced quantities of their new trees and shrubs. They certainly did not produce more than a dozen or two seedlings of A. griseum. Sometimes people are lucky who gamble on the ultimate value of a new plant; they are now reaping the benefit in the case of A. griseum, for they have shapely young trees of what is probably the finest of all the maples. It is handsome in the summer, turns a fine colour in the autumn, and has an added advantage in that its bark peels in large flakes, showing the new orange-coloured bark underneath; this is a habit common enough in birches, but rare in maples. As time went on the beauties of this plant became recognised and a demand started, but there was no supply. This acer will not allow itself to be propagated and only in the past year or two has it begun to set fertile seed. Seedlings may possibly be in commerce in 1926, after a delay of twenty-five years. And yet we cannot blame anyone for this delay. It is an extreme instance.

One more example: many years ago Messrs. Cunningham and Fraser introduced a fine yellow-flowered rhododendron, perhaps a species, possibly a hybrid, called Cunningham's Sulphur. At the time it gained a moderate degree of popularity, and then for some unknown reason the demand stopped, and shortly after the supply also languished. Towards the end of the war Sir Isaac Bayley Balfour suddenly realised that this treasure was threatened with extinction. The raisers did not possess a single plant. Owing to Sir Isaac's foresight Cunningham's Sulphur has been saved and is again in commerce; but what an escape. This affects the question of supply and demand from a different angle. Why this sudden stoppage in demand?

I have come to the conclusion that gardeners are little different from all other consumers. Let them get a habit and they will stick to it—for a time. But every now and again their memory has to be prodded, otherwise they forget. This prodding may be accomplished by propaganda by a band of enthusiasts, by constant reference to a plant in books or in the horticultural press, or by advertisement. The first two methods are perhaps obvious, but many consumers do not realise the value of an advertisement. Its primary importance is not always that it is a direct incentive to buy at the time of issue; it is useful in that it reminds people that such an article exists. There is the well known case of a universal household commodity which stopped advertising for the sole reason that the owners considered the article to be so well known that any further advertisement was a waste of money. The sales in the first year dropped to such an extent that the result was nearly disastrous. The advertisement in this case was a reminder pure and simple.

It is just the same with nurserymen and their wares. They advertise not entirely with the intention of making an immediate sale, but also to remind gardeners of their existence and of the existence of particular plants. Customers' memories are sometimes weak. In the same way THE GARDEN is constantly reminding readers of the existence of plants which are worthy, whether old or new. Although we pride ourselves that the more perspicacious of our readers use the paper as a work of reference, yet we realise that some make use of it week by week in order to jog their memories. We try to be eclectic and make the paper useful for every kind of garden lover.

This question of supply and demand may perhaps explain the reason why it is a necessity of occasion to mention plants which are difficult to obtain, for we are sometimes blamed for writing about rare plants. Unless a plant is asked for by the public, there is no incentive for a nurseryman to keep a large stock of it, and so a plant, however worthy, may suddenly fall into oblivion. It is only by bringing such plants to the notice of our readers that a demand is created, with a corresponding increase in supply. However well intentioned a nurseryman may be, he has to work for his living, and to produce numbers of a plant for which there is little or no demand may prove a disastrous speculation. This article may appear to bring the commercial instinct into gardening, but even hobbies may be the better for a slight admixture of economics.

A CONTINENTAL BOTANIC GARDEN

BY GEORG BROCHNER.

SWEDEN has for centuries been to the fore in the matter of botanical research, including the creation of gardens specially intended to facilitate such studies. As much as three hundred years before the time of Linnæus, between 1620 and 1630, Bishop Johannes Rudbeckius laid the foundation of what is no doubt the oldest botanic garden in the country, the Viridarium Gymnasii at Västeras, which is still in existence; and his famous son, on his own initiative and at his own expense, in the year 1655 formed the Hortus Botanicus in Upsala. The great Axel Oxenstjerna on a visit to this ancient centre for learning had already, in the year 1637, urged the laying out of a botanic garden in connection with the university in this town and the study of medicine. Although Gothenburg, which has always been a rich and generous city, enabled several of the disciples of Linnæus to undertake costly explorations in distant lands, none of these in return gave the impetus to the formation of a botanic garden in the town, which, strangely enough, allowed itself to be left behind in this field by other Swedish towns.

A GENERAL VIEW OF THE BEDS. WITH THE STATUE OF LINNÆUS IN THE BACKGROUND.

THE SMALL POND IN THE GARDEN IN A TYPICAL NATURAL SETTING.

It is only ten years since a munificent donation by a Gothenburg citizen enabled the town to realise a long-cherished wish, and the new botanic gardens were opened last year in the presence of a distinguished gathering, which was unanimous in its praises.

The site is admirable, one might well say unique, and covers an area of about 900 acres. This allows room for everything, also for preserving portions of this picturesque spot in its primeval beauty. The gardens boast rare natural advantages, hills—one might say small mountains—streams, clefts, moorland, groves, vistas of wide and great beauty, and Professor Carl Skottsberg, who almost from the very beginning of the work in connection with the gardens has been the *primus motor*, will see that no one molests or interferes with all these charms.

In spite of all this, the place chosen has its drawbacks. The soil, for instance, is by no means genial, in some places almost forbidding, but admirable headway has already been made in the direction of improvement and the gardens are still in their infancy. Professor Skottsberg has, luckily, been given a free hand, not being trammelled by the considerations which, with one exception, prevail at all the botanic gardens in Sweden, Denmark, Finland and Norway, which are university institutions and thus have to fulfil a distinct mission. Professor Skottsberg, who is a widely travelled man, at once realised that as regards the Gothenburg Botanic Garden other views should be adopted. It might become more of a popular institution in which all classes could find delight—an object lesson in geographical botany without too stringent scientific limitation and, last but not least, æsthetic considerations must not be neglected. With this programme in the able hands of Professor Skottsberg, and the alluring natural conditions, the new gardens will assuredly before long have gained a world-wide and well deserved fame.

The flora of many parts of the world has already had its own particular domain allotted. Close to the western boundary we find a portion of America, while Eastern Asia has a central position, with Siberia sloping down to the west, the Orient more to the east, and so on. The many undulations of the ground afford a variety of natural conditions which are being turned to excellent account.

All who love alpine plants—and who does not?—will pilgrimage to this ideal enclave where they will no doubt also find some of Sweden's own sweet herbs, Arctic or otherwise. The Swedish flora boasts many treasures; to mention one, the daintily scented Linnæa borealis, of which flaxen-haired little maidens offer the stranger modest bouquets and on which Linnæus himself set such store that he planted it in his coat of arms. A tribute has already been paid to this great representative Swede in these gardens in the shape of the statue which will be seen in one of the illustrations.

Digitized by Google

A typical Swedish manor house was found in the grounds. This has now become the residence of the Professor, and on both sides of it a formal garden has been formed, in harmony with the building and old traditions.

Other botanic gardens, no doubt, possess bigger and more ambitious glass-houses than the one at Gothenburg is ever likely to have, but it can safely challenge any of its fellows, in Europe at least, to equal it in the singular beauty of its *landscape*, with narrow winding pathways, steep ascents, steps and streams and ponds, nooks with seats, many a point of vantage from where one views the width and grandeur of the west Swedish country. Vegetation is strangely prolific in parts of Sweden, reminding one of what may be met with in much more southerly latitudes. Trees, too, are often possessed of a rare, impressive beauty, and in the Gothenburg Botanic Gardens. There are some magnificent oak trees, which shelter and cluster round a small but very attractive pavilion, designed by Professor Wahlman.

CORNUS SUECICA GROWING IN THE WILD STATE IN THE PARK.

Much, however, is still in its infancy, but there is plenty of scope and Professor Skottsberg is rich in initiative. No special section has, as yet, been set aside for American alpine plants, but the formation of a second alpinum is already on the tapis. The "rock gardens" (although the term is rather a misnomer) are meant to be very exclusive; they are reserved for real alpine vegetation and are barred to less genuine alpines, albeit attractive and decorative plants which are gladly admitted to many a rock garden of distinction. A stream on its way creates favourable conditions for various species until it reaches the sub-alpine meadows. I wonder if any botanic garden has ever been located under surroundings richer in beauty and taken in hand with a fuller conception of its possibilities than the one of Sweden's great west coast city.

INTERESTING TULIPS

MR. JACOB SHOWS THAT MODERN COUNTERPARTS EXIST OF MANY OF THE OLD FAVOURITES OF THE SEVENTEENTH CENTURY.

IF we make a garden of interest it is very necessary that the owner thereof should have a tongue wherewith to speak to visitors on behalf of its occupants. Flowers only have the power of telling us that they are beautiful and that they are sweet scented. In the days when the doctrine of signatures was in vogue, it was gravely argued that plants even had the power of suggesting their utility for medicinal purposes. But however that may be, it is certain that they are dumb, with a doubly portcullissed tongue, as far as being able to give one single positive hint themselves to account for their presence in the surroundings in which they find themselves. No doubt anyone who visited Tradescant's Ark was already prepared to see objects gathered together primarily for their interest, and with sufficient knowledge might have understood their presence. Just so certain gardens of modern times have become famous for the interest of their occupants rather than for their beauty or extent. Such an one was Edge Hall, Cheshire, in the days of the Rev. Charles Wolley-Dod: a garden of difficult plants living in health. But interest is many sided. There is, for example, the interest of history and the interest of novelty. Some tulips of which I am about to write demand admission because the superscription on their tickets is "Historical," whereas on others it is "Novelty."

I have often met people who have never heard of the tulip mania in Holland in the years 1635 to 1637. They naturally will have no wish to know what kind of tulips were then current coin among the dealers. On the other hand, let us suppose they know a little about it, they are surely curious enough to want to know what they were like. They are seldom seen anywhere nowadays. The old order has changed in more ways than one. We have Rembrandts or broken Darwins, and we have broken old English and May-flowering tulips, but the striped flowers of the mania time were none of these. They were all, or practically all, early or midseason bloomers. This induction from Parkinson and Ray is more than confirmed by van Kampen in the "Dutch Florist" (1764), where it is distinctly stated that it was "the spring tulips, which blow at the same time with the hyacinths, which were formerly in so great reputation that the florists placed their highest ambition in the possession of them." Semper Augustus, Gouda and Viceroy are now no more, but passable reproductions or reminders are to be found in Roi Pepin and Admiral Reyniers for Semper Augustus and Gouda as rectified "roses," and in Globe de Rigaut for Viceroy, which seems to have been a pale bybloemen. There are a fair number of early-flowering rectified tulips still to be found in catalogues. A bed of these would be most interesting. "These, friends, are not the actual tulips that were in existence during the mania, but they are of the same type, etc."

As a little collection I would suggest Admiral Reyniers, Roi Pepin, Globe de Rigaut, Grootmeester van Malta, Comte de Vergennes, Silver Standard, Silver Bride of Haarlem, Royal Standard, Golden Bride of Haarlem and Duc de Berlin. I am not sure if all these can still be had. Most of them can. A bed made up of some of them would be a centre of interest to all who are *historically* inclined.

The second group to which I would call readers' attention, and of which a bed might be made, is, as far as I can make out, a group within a group. Side by side with the striped and blotched varieties in pre-mania times there existed a class distinguished by their petals being of a self colour, each with a well defined edge all round it of another colour. One part was called the "Duc" class, and if we grow the early Duc, which in Carter's catalogue is called "Scarlet and Gold: red with yellow edge," we would have in our gardens practically one of the same edged varieties that Jean Franeau pictured in "Le Jardin d'Hyver" in 1616. There are several of these edgers featured and described there. The most uncommon of all was a white with a well defined black edge round each petal. A friend of the author's told him he had seen such an one in Brussels in 1615, and, quite in accord with the fashion, described it as "un chef d'œuvre de Flore." Our author goes in ecstasies over it. "Nonpareille beauté," "Miracle des Fleurons," he calls it. Whether such a flower ever sa

Digitized by Google

the light of day or not, it is very certain that at this early date there were numerous varieties of rich red-purple shades edged with white or a pale yellow. These were sufficiently distinct to form a class by themselves. They seem to be what Parkinson describes as "Princes," and are the same as those we now call "Lacs," as, for example, Lac van Rhijn. There seems to be very little doubt of this variety being in existence before 1635. If so, it is one of the oldest of all our tulips. To create a spot of deep historical interest, fill a small bed with Lac van Rhijn, Mrs. Elwes, Eleonora and La Remarquable, you will then have samples of one of the most popular types among the earliest cultivators of the tulip. How or when the term "Lac" originated I do not know. Among the books to which I have access the earliest use of the word is to be found in the "Flora Ceres and Pomona" of Rea in 1665.

From the very old I pass to the very new. Some of the wholesale houses of Holland offered this year an entirely new race under the name of Mendel tulips, but I cannot find them in any of the English retail lists that so far have come my way, I therefore conclude dealers want to try them themselves before they offer them to the public. They are the result of crossing Duc van Thol tulips with Darwins, and are said to "present many new and uncommon colours and are valuable for early forcing." They have been raised by the firm of E. H. Krelage and Son. I am giving these new-comers a trial both under glass and in the open. To me they are veritable pigs in a poke. I never heard of them until last spring, and although I have now handled the bulbs I will have to wait until 1925 to see them in flower. I very much wonder what is in the lap of the gods, or, to be very matter of fact, in the pots in my greenhouse and in the beds in my garden. I have purposely refrained from trying to make readers' mouths water over Mendels. All I know about them is what "they say," and, like wise old John Mandeville, the globe trotter of St. Albans, I do not commit myself too far on mere hearsay evidence. I only say they will be a most interesting "wait and see" for me. Now for a few mouth-waterers. They can all be had from one source or another if you are prepared to pay the price. Most of them are recent introductions, and every one may be said to be given away if what is asked be compared to what Gouda, Viceroy and Semper Augustus sold for in the years when Holland went mad. Arethusa, an ideal deep yellow Cottage, the *it* of the type; Orange Perfection, a beautiful rose Darwin steeped in a bath of orange; Zwanenburg, the new white Darwin with black pollen; Marksman, a fine scarlet Cottage variety, very bright; The President, pure orange, rather dwarf; Fantasy, a "parrot" sport from Clara Bull, very charming; Canary Queen, which flowers at the same time as White Swan, a very beautiful pale yellow with lemon edge; Prince Albert, a gem for the lover of "browns"; Goudvink (syn. Goldfinch), another brown gem, but whereas Prince Albert is a long flower, this has big coffee-cup sized blooms; Carrara, a white cottage, not such a graceful plant as Zwanenburg, but some people may prefer it as it has yellow pollen; Zomerschoon, one of the loveliest of tulips, a relic of the distant past if it be identical with the mania-time one with the same name. I only doubt it because of its late time of blooming, but it may have been an exception. Soft salmon rose markings on the very palest of primrose ground. General de Wet (syn. de Wet), the beautiful orange red sport from Prince of Austria; Charm (Dobbies'), a blue-blooded old English tulip which seems inclined to remain a self, pure white base and shaded rose petals. All these are out of the way and for many will have the interest of novelty.

JOSEPH JACOB.

FRIENDS AND FOES OF THE GARDEN—III

BY CLIFFORD W. GREATOREX.

ONE of the most beautiful of all our common birds is the greenfinch, known in some localities as the green linnet. So familiar is it that few people realise its loveliness of coloration. A cock greenfinch in his summer dress seems more like a denizen of the tropics than an inhabitant of our own temperate land. Bright yellow, green, greenish yellow, black and dusky grey are included in the colouring of this bird.

Though often associating in small parties, greenfinches are heard more frequently than they are seen. The long-drawn call-note of the greenfinch—rendered by one naturalist "dwee"—is distinctive. Unfortunately, this bird has rather a bad name. Gardeners do not like it—not without reason. In the spring it nips off the buds of the trees. This, however, is the only charge that can be brought against it. And, be it remembered, on the other hand, we ought to consider that greenfinches devour great numbers of insects, especially when there are young to be fed—a statement applying to all finches. In winter they consume the seeds of many harmful weeds, such as charlock and spurry. The greenfinch often nests in orchards and in large gardens, and when it does so its value as an insect—and weed—destroyer should be set against its harmfulness as a spoiler of buds.

The pretty chaffinch is useful in the garden, and deserves protection. Truly, it is a seed-eater, but chiefly in autumn and in winter, and then it visits the stubble fields and stack-yards. However, the farmer has no reason to object to the chaffinch's visitations, for it is taking only the waste grain which, unless removed, is all too likely to attract rats and mice. The main diet of this bird throughout spring and summer consists of insects. Aphides are sought for and eagerly devoured, and there are very few small moths whose larvæ are secure against the attentions of the sprightly, bright-eyed "spink."

A very striking bird is the hawfinch. However, the gardener's maxim is—of necessity—"Handsome is as handsome does." Therefore, the hawfinch is regarded as an enemy. Its attractive appearance does not atone for its destructiveness. This bird has an annoying habit of inflicting injury upon the peas and leaving the gardener in doubt as to the origin of the offence. It is wondrously skilled in the art of keeping out of sight. It has learnt the wisdom of visiting the garden when mankind is sleeping. Early in the morning, sometimes with the first glimmer of dawn, this bird takes heavy toll of the choicest peas, splitting the pods expertly from end to end and extracting the contents as cleanly as though the work had been done by human hands. Fruit, too, is consumed; the hawfinch's great beak can crack the hardest plum or cherry stone with ease. He who would outwit this bird must sacrifice his rest. Even then, should he manage to arrive on the scene in time, the chances are that

THE BULLFINCH, HANDSOME BUT DESTRUCTIVE IN THE GARDEN.

Digitized by Google

his intended victims evade him! Indeed, so wary are hawfinches that one writer remarks: "It is possible to get within gunshot of these birds only by the use of a decoy, or by imitating the birds' call-notes, which are not unlike those of the robin." And, unless the early morning expedition be successful, nothing further can be done that day. For, when the world in general awakens, the hawfinches retire into the depths of the woods, or, in orchards, conceal themselves high up among the dense foliage of the trees.

A friend of mine has just made a suggestion for the protection of peas from the hawfinches' disastrous attentions. It may or may not be practicable. I offer it for what it is worth. These cunning robbers might be scared away were a very loud-toned alarm clock placed between the rows, and set so that it would go off just about dawn. Better still would be a specially constructed alarm that would continue to ring for, say, an hour. But, of course, the birds would get used to it after a time, and would continue their depredations just as if the alarm-clock were not there.

THE SHORT-EARED AND LONG-EARED OWLS.—EXPERT IN RAT CATCHING.

Another very beautiful bird that ranks among the foes of the garden is the bullfinch. This is a regrettable fact, because the bullfinch is a truly handsome creature. But, alas! it has been seen, time and time again, in the very act of destroying the fruit-buds—and these buds are by no means always infected by insects. Even the most devoted lovers of birds are obliged to admit this failing on the part of the bullfinch. The bird will perch on a branch, nip off every bud within its reach, and then deliberately move to a fresh place and act in the same manner there. The buds of currants and gooseberries also are destroyed. These offences are serious, but, during the greater part of the year, the bullfinch's food consists of weed seeds. The man who can devise some means whereby the buds are safeguarded against the attacks of bullfinches without the necessity of destroying the birds themselves will have performed a valuable service to both the gardener and the naturalist.

It would be rather difficult to find a very good word to say on behalf of the house-sparrow, save that, when there are young to be catered for—a state of things occurring three or four times every year—it destroys large numbers of insect pests. Unfortunately, however, the very plentifulness of this bird renders it a nuisance. It has been obliged to develop catholic tastes. In spring sparrows attack crocuses and primroses, not to mention other valued garden flowers. As soon as the gardener plants the seedling peas, "the little brown birds" set about bringing his labours to naught. Yet, they include aphides and saw-fly larvæ, together with the seeds of various weeds, in their dietary. In moderate numbers sparrows would not be so troublesome, but their numbers are not moderate, and they take too great a share of the products of the garden.

One of the most valuable, and at the same time one of the most retiring, of all the gardener's feathered friends is the barn owl. This fascinating bird spends the daytime sleeping—and snoring!—in a hollow tree, in a cavity in an ivied wall, or in some suitable nook in barn or outhouse. Not until the shadows lengthen does it appear, and then—woe betide the mouse or the rat, the vole or the mole that happens to catch its ever-watchful eye! There is not even time for a scuffle. A sudden descent—absolutely noiseless—a grip of needle-pointed talons, and the owl has secured its victim. All the owls are of great use, and in rural areas the garden is sometimes visited by the brown owl and the long-eared owl. The latter is a keen hunter of sparrows, which it seizes while they slumber among the ivy. And not even the largest and fiercest of rats can resist the lightning attack of any one of these expert hunters.

WINDOW-BOXES

FLOWER-LOVERS who are gardenless because fate obliges them to live in towns or cities can satisfy their longing in this direction by window-boxes. Not the hackneyed ones with geraniums, calceolarias, marguerites and lobelias, but boxes which, like gardens, express the individuality of the owner, being arranged according to his fancy and planted with his favourite flowers. The boxes should be begun in October or November and filled with good loam mixed with leaf-mould and a little rotted manure. Wallflowers, Brompton stocks and intermediate antirrhinums (stocky, sturdy plants) are planted, together with bulbs of all kinds—daffodils, narcissi and all tulips save Darwins (which blossom too late and whose flower-stalks are too long). In the front of the boxes crocuses of every hue may be planted, or golden ones only mixed with gentian blue Siberian scillas, or grape hyacinths. Should the winter be mild, the wallflowers and stocks will blossom before it is over. For window-boxes in the shade, Victoria forget-me-nots and the mossy saxifrages should form an edging. The latter are a lovely green during the winter, and are smothered with pink, red, yellow and white flowers in the spring. Towards the end of May the soil is renewed and the boxes planted for the summer. Those in the shade with ten-week stocks, asters, in all the lovely new shades, and fuchsias. Mimulus, canary creepers or petunias, which hang down and cover the boxes, make showy edgings. Annuals of all sorts can be used in other boxes. Clarkias, marigolds, snapdragons, larkspurs and the like, heliotrope and the stock-scented summer wallflower (Cheiranthus Allionii) with its orange blossoms make a charming contrast planted in the same box. The wallflower should be kept constantly picked.

For bedroom window-boxes sweet-scented plants should be used, such as mignonette and night-scented stock. Each box should have a small plant of lemon-scented verbena, and Cupid sweet peas form a fragrant edging. Trailing lobelias and campanulas are planted to hang down and cover the sides. Another scheme is to fill the window-boxes with pompon or polyantha rose bushes, having a different variety for each box. These are most effective if used with any of the edging or hanging plants already mentioned. A little fresh soil should be added occasionally. VICTORIA SLADE.

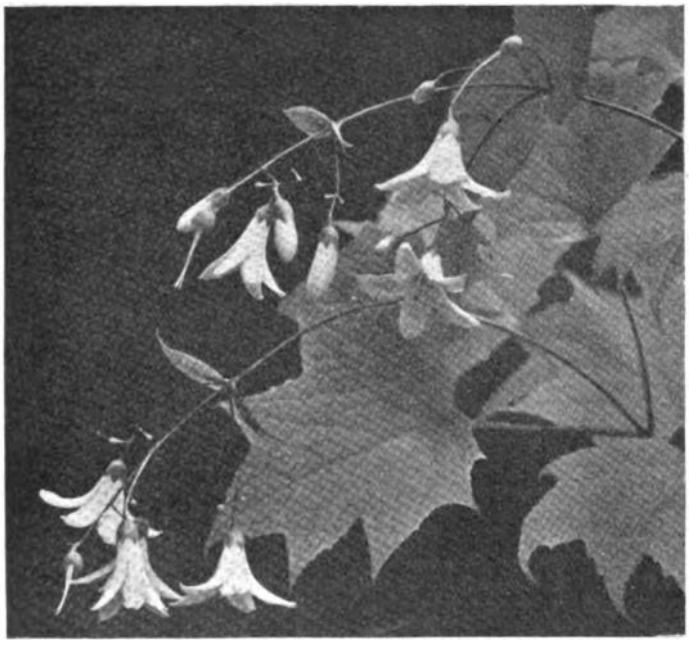
NEW AND RARE PLANTS

KIRENGESHOMA PALMATA.—This plant, with the curious name, is a Japanese herbaceous perennial of great interest and of no small garden value. It seems to be still very rare in Britain, as well as in the gardens of the Continent. I believe that it was advertised years ago in Dutch catalogues. I was quite surprised at its singular beauty when I saw the plant in flower in the Botanic Garden at Nymphenburg, near Munich. This garden, by the way, is the most interesting and best kept of the numerous botanic gardens in Germany. It has an extremely fine rock garden, and close to it there is a long, shady walk with borders of ferns and other shade-loving plants. Here stands a fine specimen, with its handsome dark foliage, of the Kirengeshoma, forming a broad clump, and in autumn almost covered with graceful, nodding, loosely-flowered inflorescences. The plant is sometimes called a sub-shrub, but I do not think that even its rootstock becomes woody. It is a striking representative of the saxifragaceous family. The shape of the flowers and of the leaves may be seen in the accompanying illustration. The flowers appear rather late in the season and seem to last for several weeks. Their colour is a pale, somewhat waxy yellow. Large inflorescences bear from twelve to over twenty flowers. The whole plant reaches a height of about 2ft. to 2ft. 6ins. It is a plant of the Japanese woods, and it likes a shady place under deciduous trees such as beeches or oaks. I do not know if the fruit ripens freely. To propagate it it seems necessary to divide strong plants which, of course, is a slow operation. Kirengeshoma is a very valuable shade plant because the number of herbaceous perennials of its size and beauty that grow in a rather deep shade is not large. Large groups of it in a wild garden along a shady walk would be unusually effective

SALVIA GLOBOSA.—Many years ago the Dendrological Garden at Prubonice, near Prague, received seeds of an interesting species of the genus salvia from the well known plant collector, Walter Siehe, at Mersina, Asia Minor. This salvia has been distributed under the name S. globosa or S. verbascifolia var. globosa. I am not sure whether this latter identification is a correct one. The true verbascifolia comes from the Caucasus where I collected seeds myself in 1909. S. globosa, the plant from the Cilician Taurus is very showy when in flower. The illustration represents a good specimen. During the first year the plant only forms big rosettes of handsome leaves, but in the second season there spring up the large panicles of almost whitish or creamy flowers. During the month of August such well developed plants are lovely. Together with certain verbascums and other tall summer-flowering plants they form striking features in the wild garden. They prefer a rather dry and sunny position with a deep, well drained soil. In their native country they grow on sunny hill slopes, and like some of the majestic verbascums, they occasionally cover whole mountain sides. It is a pity that the plant is not a perennial, but it can easily be raised from seed.

CAMILLO SCHNEIDER.



A VALUABLE SHADE PLANT, KIRENGESHOMA PALMATA.

LARGE HANDSOME ROSETTES OF SALVIA GLOBOSA.

NATIONAL CHRYSANTHEMUM SOCIETY'S SHOW

THE great popularity of the chrysanthemum was never more evident than on November 6th last, the first day of the annual show of the National Chrysanthemum Society, when the Royal Horticultural Hall, Vincent Square, London, was most uncomfortably crowded for several hours with lovers of the flower who endeavoured to view the exhibits. Although the dozen selected varieties from the forty novelties which were placed before the Floral Committee received their full mead of attention it was interesting to note the difference between the chrysanthemum and the rose enthusiasts. At the shows of the summer flower it is the new varieties that are the main attraction, but with the autumn flower the large competitive classes receive first attention and notes are taken of the varieties which make the widest appeal, and we feel certain that many who visited the show did not trouble to look for the new varieties at all. There should be a moral somewhere in this, but it does not seem to be self-evident.

So far as the exhibitors are concerned the most popular chrysanthemums to-day are the enormous exhibition Japanese and the large-flowered singles. The classes for these types were practically all well filled and there were very few of the small singles, anemone-flowered, incurved or pompons. While there is an undoubted demand on the part of a considerable number of exhibitors for opportunities of showing their monster blooms on boards, yet the large exhibition blooms were much more attractive when shown in vases. In nearly every case the exhibition blooms have outgrown the space allowed by the boards so that they are too crowded to be seen properly.

The classes for large Japanese blooms in vases provided an opportunity for selecting the best varieties. Louisa Pockett was placed first among the whites, but we preferred the greater purity of Queen Mary, which is also an immense bloom. The yellow class was very disappointing in that the chief prizes were awarded to Mr. R. C. Pulling of unlovely greenish tinge, though the blooms were perfect as regards size and shape

Digitized by Google

and freshness. William Rigby, also of great size, is of far better colour, as also is the slightly paler Princess Mary, while Shirley Golden, which has narrow florets, is more graceful than either. Majestic, of delightful golden amber colour, and Mrs. George Morris, intense crimson, could scarcely be improved upon. Mrs. John Balmer has long curly florets of bright India red with golden reverse. F. Spring Watts, chestnut and gold, and Mrs. B. Carpenter, rosy mauve, were excellent.

Of the many large singles we selected Sandown Brilliance, crimson; Mollie Godfrey, bright mauve; Mensa and Nora, white; Pridle and Phyllis Cooper, yellow; Absolute, crimson bronze; Lady Astor, velvety crimson; Pink Beauty and Coronet, golden buff. In the competitive classes there were no really good small singles, but Messrs. Cragg, Harrison and Cragg showed delightful vases of this elegant type. Flavia, bronzy yellow; Ceddie Mason, crimson; Orlando, yellow; Portia, reddish bronze, and Clytie, were very charming examples. This collection, which was most delightfully arranged also included the best selection of the useful "Market Japanese" varieties. Aldyth, bright rich crimson; Isolde, pale lemon yellow; Felix, bright chestnut red; Jean Pattison, coppery bronze; A. Brooker, incurving red, showing golden reverse; Blanche du Poitou, one of the finest whites of recent introduction, and Sorcerer, bright bronze with golden tips, are valuable sorts.

The large trade groups of chrysanthemums were a great feature of the show. These showed every care and attention in their arrangement, the individuality of the blooms being shown to advantage. Mr. H. J. Jones was awarded a large gold medal and the Clay gold medal for a magnificent collection. Messrs. Keith Luxford and Co. received a large gold medal, and gold medals were awarded to Messrs. W. Wells and Co., and to Messrs. Cragg, Harrison and Cragg, for their splendid exhibits.

One of the outstanding exhibits was that of four very large pot plants of the brilliant Mrs. R. Luxford, shown by Mrs. Douglas Joy, Marylands, Bartley, Hants. On one of the plants there were no fewer than eighty-eight blooms, all of good useful size.

NEW CHRYSANTHEMUMS

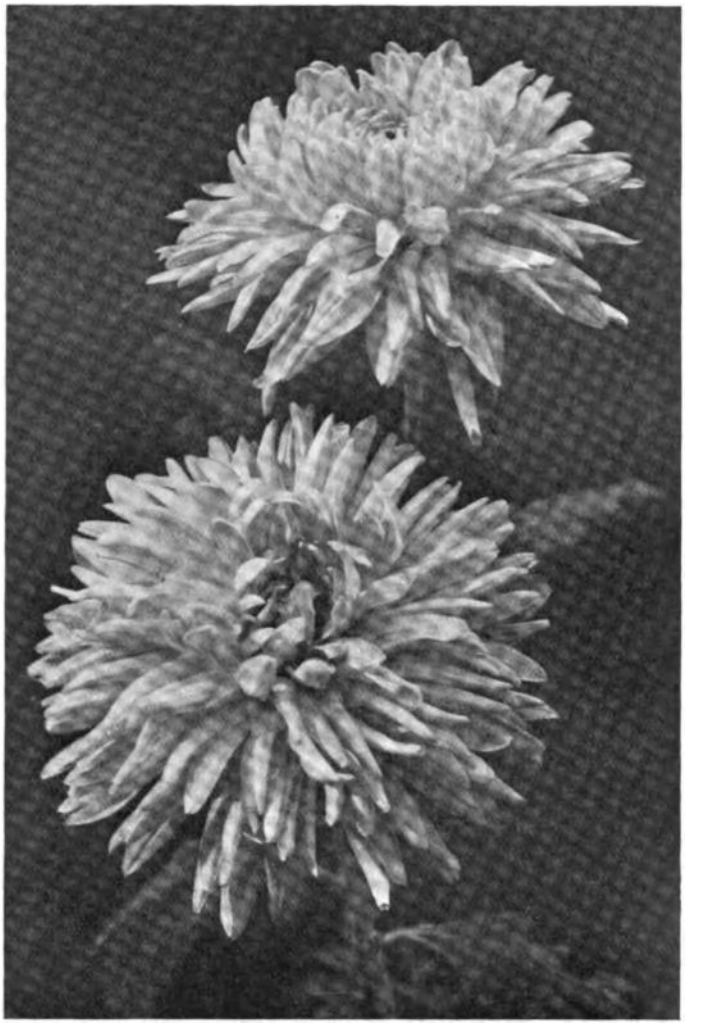
ANNETTE.—This is a large, well formed single of deep yellow which is heavily stippled with bright chestnut on the outer parts of the florets, giving a delightful effect. First-class certificate. Shown by Messrs. Cragg, Harrison and Cragg.

ENNISMORE. — An exhibition Japanese variety of elegant shape and pleasant light chestnut colouring. It is a welcome addition to its class of bloom. First-class certificate. Shown by Mr. William Scutt.

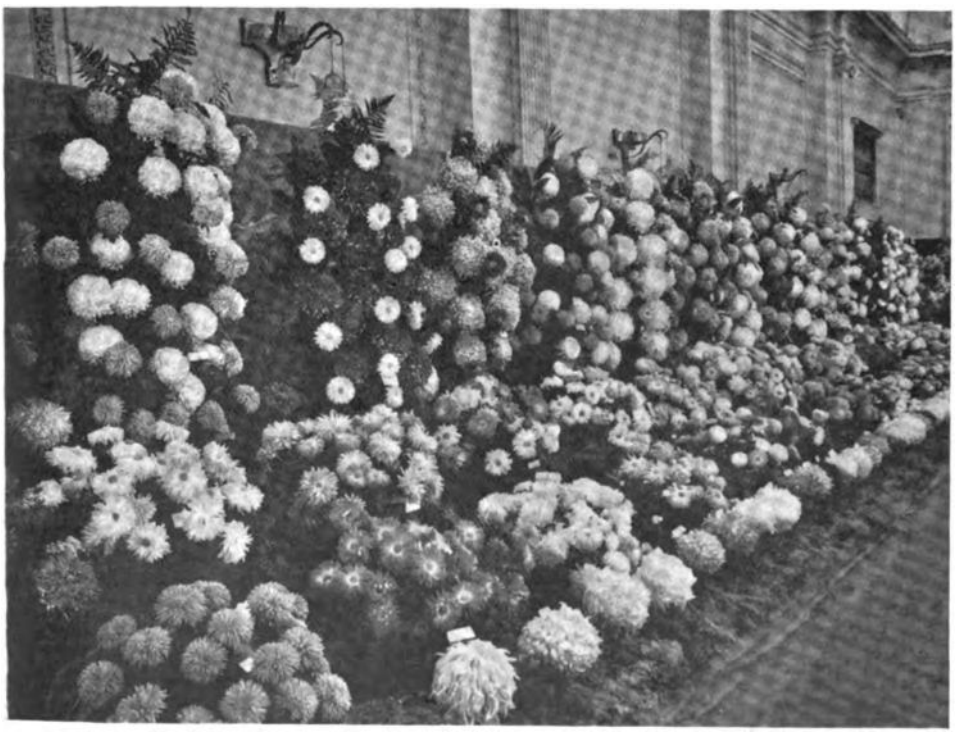
HARMONY.—A Japanese variety of the size most valued for market purposes. It is of glowing terra-cotta colouring and has a light gold reverse. First-class certificate. Shown by Mr. H. Shoesmith.

HON. EDITH SMITH.—This very large single chrysanthemum does not bear close inspection, as it is of poor type. The broad, loosely set florets are heavily flushed and lined with mauve. First-class certificate. Shown by Mr. W. Turner.

J. SYMONDS. — A large exhibition Japanese variety of great depth of bloom. The broad florets are of pale canary yellow colour. First-class certificate. Shown by Messrs. Keith Luxford tnd Co.



HARMONY, AN EXCELLENT VARIETY FOR MARKET PURPOSES



THE MAGNIFICENT COLLECTION OF BLOOMS STAGED BY MR. H. J. JONES.

MR. T. SLACK.—An exceedingly handsome large Japanese variety of the best exhibition type. The long broad florets twist and the golden reverse alternates with the bright reddish chestnut surface colour. First-class certificate. Shown by Messrs. Keith Luxford and Co.

MR. W. PETTY.—An exhibition Japanese bloom of large size and rosy bronze colouring. First-class certificate. Shown by Mr. Baxter

NAN LUXFORD.—This is a rather more than medium sized incurving Japanese bloom of considerable substance and delightful silvery mauve colouring. First-class certificate. Shown by Messrs. Keith Luxford and Co.

SPARKLER.—A perfectly formed single variety of nearly Mensa size and glowing ruby crimson colour with a narrow golden zone. Card of commendation. Shown by Mr. J. Barrell.

STIRLING STENT.—An exhibition Japanese variety of washy mauve colour, which has only large size to recommend it. First-class certificate. Shown by Mr. Baxter.

SUNBURST.—A well formed, medium sized Japanese bloom of fawn colour or terra-cotta shaded with salmon. First-class certificate. Shown by Mr. H. Shoesmith.

THOMAS POCKETT.—A very large exhibition Japanese variety. The long, broad florets curl and recurve. The general colour is pale mauve with a silvery reverse, but the centres of the blooms are of brighter tint. This variety has been named after the famous raiser and grower of Chrysanthemums in Australia. First-class certificate. Shown by Messrs. Keith Luxford and Co.

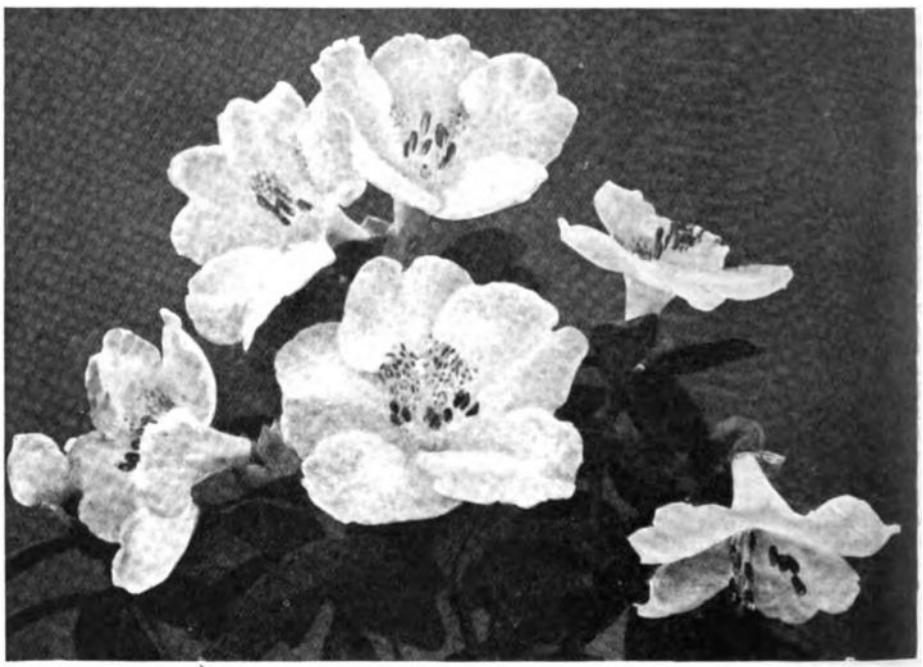
A RHODODENDRON HOUSE

BY E. H. M. COX.

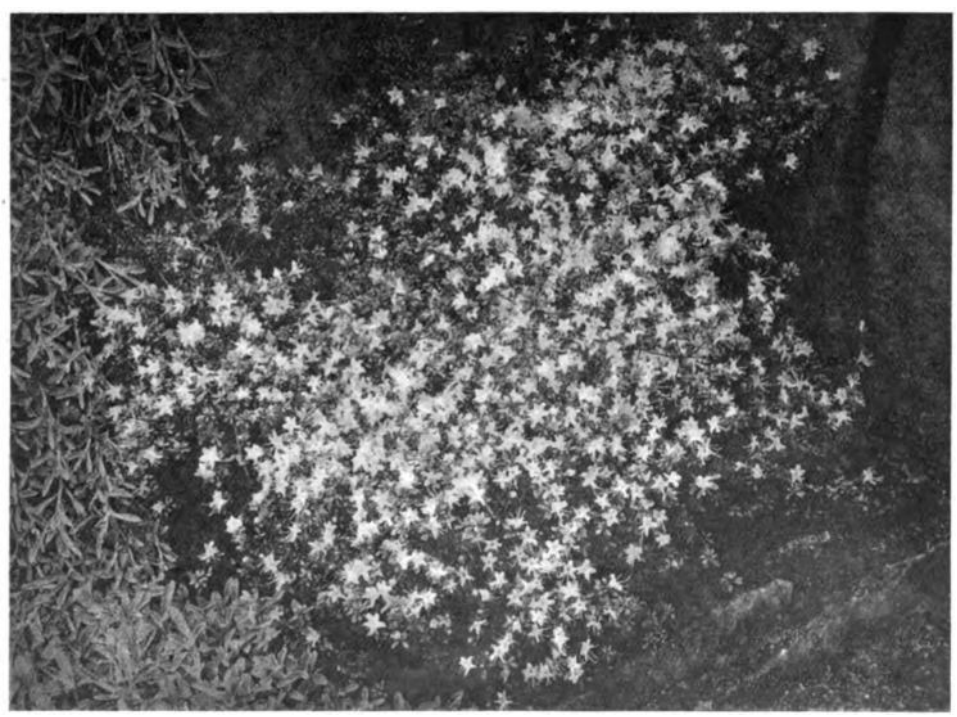
AT the present time, with the large influx of rhododendrons into this country—no article on rhododendrons ever seems to begin without some excuse as to their numbers—several species have arrived on the scene which are, perhaps, of doubtful hardiness; they break too early in the spring and are in consequence frost-bitten; in short, there are a number of rhododendrons which would be the better for living indoors. Let me qualify this statement by saying that these are in addition to R. javanicum and its allies and hybrids, which are really tropical and not only require to be grown indoors but in a damp atmosphere at a temperature approaching that of a stove-house.

This article would never be written but for the fact that many people have glasshouses, originally built for palms or vines, which, owing to the cost of coal and labour, have been given up, sometimes prematurely. All that is required for rhododendrons is a sound house, which is either vacant or of little use to its owner; aspect does not matter, neither does heat. Size is also not of the greatest importance, because sufficient rhododendrons of small stature can be grown to make even a small house attractive.

The first thing to do is to remove all staging and to prepare the ground in the same way as for rhododendrons outside.



R. MOUPINENSE, AN EARLY FLOWERER, AND SO USEFUL IN A RHODODENDRON HOUSE.



A MASS OF DELICATE BLOSSOM, R. SERPYLLIFOLIUM.

Particular care, however, must be taken over the question of drainage, and about 3ft. to 4ft. below the surface a thick layer of clinkers, stones, brick or broken crocks should be laid, while the actual soil is probably best prepared with half peat litter, a quarter light loam, and the other quarter made up of coarse sand and leaf-mould. I said above that all staging should be removed, but where some is already in use, one side or even a portion of one side will make a good bed of suitable size. It is, perhaps, as well to explain why a bed is necessary: the reason is that many rhododendrons are exceedingly difficult to grow in pots. When the roof of a greenhouse slopes at a sharp angle and there is little room for plants of any height, rocks can be made use of and a position made for alpine rhododendrons something approaching an indoor rock garden.

With the exception of that of R. moupinense, the photographs which illustrate this article were all taken either in the rhododendron or the alpine houses of the Royal Botanic Garden at Edinburgh, and they show how freely rhododendrons flower under glass in what are really ideal conditions. The only conditions necessary for their success are that the soil should be cultivated and fed in the same way as is done outside, that the plants should be watered and that they should have sufficient air. Watering is best done with a hose, and all the soil, including the path, should receive its fair share. In this way the air is kept moist. During the growing season watering should be done once a day, preferably in the early morning or evening, while from July to the end of January three times a week is sufficient. If the house is exposed to full sun, it should be shaded from May to August.

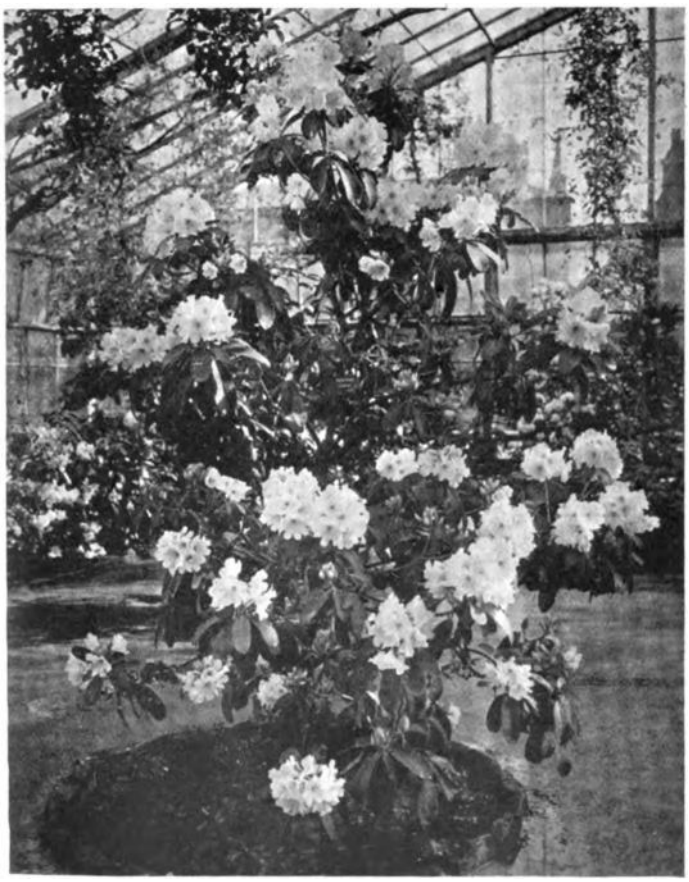
The kind and numbers of rhododendrons to plant depend upon the size of the house. Perhaps it would be better to describe the small ones first. Although the true dwarfs, coming from a high altitude, are of their nature perfectly hardy, yet they can all be grown to advantage in a cold-house. R. calostrotum, with its large rose-coloured flowers; R. myrtilloides, with mahogany-coloured bells; RR. intricatum, impeditum, scintillans and so on, are all charming little plants for this purpose, although the last three will probably have to be kept within bounds by use of the knife.

Digitized by Google

Slightly larger in size we have R. moupinense, which, although hardy, is such an early flowerer that the flower buds are usually cut outside by the frost. It is a bush which grows to 2½ft., the flowers are large and white with red spots. In this same class I would put R. spectabile (F 888), which is not over hardy except in the extreme west, R. floccigerum and R. hæmatodes, all with blood-red to crimson flowers. R. bullatum, which caused such a sensation when shown last year—it is large-flowered, white, and deliciously clove-scented, and has the added advantage of flowering at a small stage. In addition, azaleas like R. rhombicum, R. Vaseyi and all the Japanese Kurumes are of the greatest importance for decorating a cold house. Two of these azaleas are illustrated, a form of the Japanese R. Kæmpferi called Hinomayo, and R. serpyllifolium. They give masses of flower and never grow out of hand. And, of course, the old favourite of the cool house, R. ciliicalyx and its hybrids, must be included.

Big rhododendrons are more difficult to cope with, as plants which bulk large in diameter are useless in a house, unless it be of large size, and can receive the plant comfortably. R. discolor, as shown in our illustration, is certainly one of the best. The one shown is about 7ft. in height and yet is a shapely plant, and not particularly wide. Another useful plant is R. Hodgsoni, which outside is often of a muddy magenta in colour; in the house the colour seems to improve vastly in tone. Although this rhododendron is on the large size, yet it can be kept within bounds. In a large house R. barbatum should certainly be grown. It may grow to 8–10ft., but its brilliant crimson flowers are extremely handsome, and outside it is often cut, as it flowers early. But large-growing rhododendrons inside require individual treatment according to the amount of space available. It is, of course, for the smaller growers that a house is most suitable.

Naturally, other plants would be grown along with rhododendrons. Alpines of various kinds, among them the more difficult primulas, would be scattered among the alpine rhododendrons, while shrubs like Pieris formosa, that beautiful white-belled ericaceous plant which is inclined to be soft, and Camellia reticulata will thank you for the same treatment.



A MAGNIFICENT PLANT OF R. DISCOLOR IN THE RHODODENDRON HOUSE AT THE ROYAL BOTANIC GARDEN, EDINBURGH.

THE FORMS OF R. KÆMPFERI ARE PARTICULARLY AMENABLE TO TREATMENT IN A COLD HOUSE.

Then lilies can be grown in the beds and will give their share of attractiveness when the rhododendrons are past.

The cool house is only in its infancy, but it is of never failing interest, and the improvements that can be made from year to year are unending. To those who have an old house at their disposal such a scheme as I have roughly sketched is well worth a trial.

THE INVENTORY OF A GARDEN

THIS property is sold, and, while the appraiser goes round the house with his notebook, I take the garden's inventory in my heart. The antirrhinums (a flower I do not really love) form a yellow-orange-red " batik " shawl, stretched under a grey-wall—the effect of an antique shawl, for there are ugly rents in the *ensemble*, owing to the moles.

The peaches on the wall, owing to the sunless summer, are hard and spotted, so as I am going away I have let honeysuckle and Bignonia radicans cluster over the tree. The bignonia riots in France, but in England I rarely see it, even on a south wall. Below this welter is a lavender retreat where I have put a stone bench. Out of this lavender there waves gracefully Salvia azurea grandiflora.

The hollyhock leaves are ugly with rust and the French gardener forgets to burn them, undoubtedly intent on the 7ft. high stems on which double flowers, crimson and pink, bloom. I raised these from Vert's seeds.

Whatever I may feel about lavender and hollyhocks, it is upon one patch of September border that I shed a farewell tear. It has rained and rained since July, but this particular patch has grown inexpressibly lovely, and one hates to part with loveliness. An uncommon pinky mauve star bush of Michaelmas daisies is the *leitmotiv*—I wish I knew its name: it came from Blackmore and Langdon. Out of a fringe of catmint it rises, and is flanked with huge hybrid pentstemons of most joyful shades, in which rose and violet and blue somehow hold the field. There is a cunning mingling of delphiniums second blooming and several Reckitt's blue spikes of delicate Salvia patens, asking for a word before one swings on to a definite tract of floriferous Plumbago Larpentæ or Ceratostigma Willmottiæ, of pale rose phlox, and to the most unexpected pale yellow bush, as large as the largest tree lupin, of Œnothera Lamarckiana and the giant evening primrose. I describe badly the emotion of this autumn showing but not even *les roses remontant* will make my farewell so poignant as this array.

MILLICENT DUCHESS OF SUTHERLAND.

DIGGING

THE SUCCESS OF THE CROP LARGELY DEPENDS ON THE PREPARATION OF THE SOIL; AND TO OBTAIN THE BEST RESULTS DIGGING SHOULD BE DONE IN THE AUTUMN.

WITH the approach of winter, all who possess a garden will be considering digging operations. Such work should be commenced as early as possible so that full benefit may be gained from the weather. The action of "weathering" on the soil is very important, and one of the chief objects of digging should be to expose the maximum amount of the soil's surface to that action. It therefore follows that loose open digging should be aimed at, thus providing for free aeration of the soil and better drainage, and, furthermore, enabling the frost to penetrate deeper. In addition to these actions improving the tilth of the soil, and rendering it easier to break down in the spring, the frost and birds will destroy many pests which may be present. Digging should not be undertaken when the ground is frozen or covered with snow, but is best done when the soil is more or less dry; light or gravelly soils can be dug when it is not advisable to work on wet, clay soils.

The bulk of digging will be necessary in the kitchen garden, and it is best to plan beforehand the position each crop is to occupy the following season and cultivate the soil accordingly, *e.g.*, root-crops and greens require deep cultivation, either double digging or trenching, while potatoes may be grown successfully on single digging.

The plot to be dug should be definitely marked out. This is best done by stretching a garden line on either side of the plot and notching out with a spade. Where box or other live edging borders the plot the notched out line should be at least 6ins. from it.

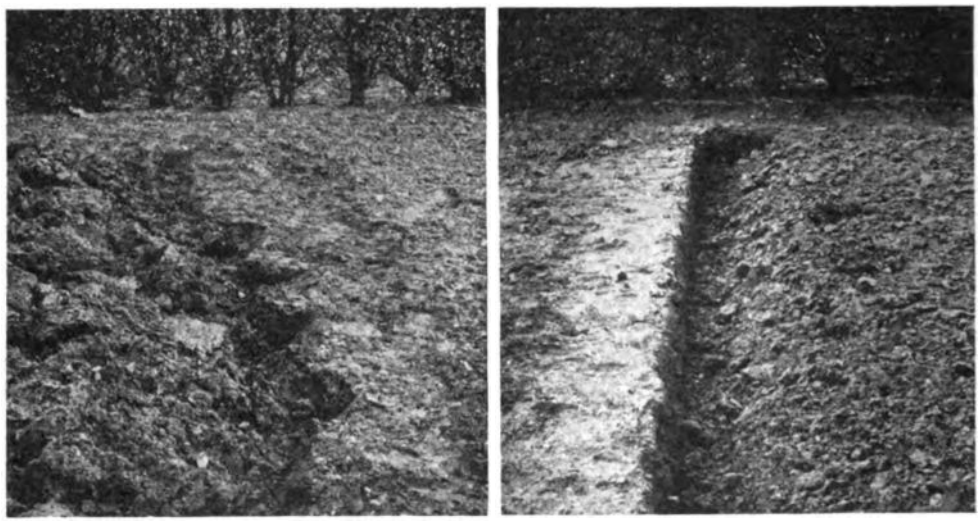
For single digging, before taking out the opening trench remove all weeds from the surface, take out a trench 9ins. wide and to the full depth of the spade, and also clean out loose soil from the bottom, and remove this to the place where it is intended to finish, a space having been previously cleaned for this purpose. Clean the surface width of the next trench into the bottom of the first, thus ensuring that any weeds present are properly buried. (Weeds near the seeding stage are best removed, as burying them will not prevent the seeds germinating at some future date.) Commencing at one end, it is best to cut the breadth of each successive spit by a sharp "jab" with the spade at right angles to the trench; the spade is then inserted almost vertically (as in illustration) to the full depth of the blade and the spit turned completely over, thus exposing to the air the soil that was previously beneath. Work across the plot in this way, maintaining a uniform depth and width, and to give the work a neat appearance the first and last spits of each trench should be turned inwards to the plot. It is in this also that the notching out of the plot beforehand proves an advantage.

It is a common mistake to lift too much on the spade. A spit of about 6ins. is sufficient on any soil. A uniform spit, in addition to maintaining an even trench, ensures that the whole of the soil is disturbed to the full depth of the spade: it is also important in maintaining a level surface, which is so essential when the time comes for breaking down in the spring.

It sometimes occurs that the soil taken from the first trench is inadequate to fill the last, but this should not happen if a good level has been maintained throughout.

For crops which require deep cultivation double digging is, perhaps, the best method especially where the subsoil is of a heavy nature. Too often one sees a wet, cold subsoil brought to the surface by trenching, and the surface spit which contains the substances for growth, is buried and very soon loses its valuable constituents. In dealing with a soil of this nature double digging should always be practised.

In double digging, prepare the plot in the same way as for single digging. The opening trench should be 2ft. wide and one spade deep and the bottom of the trench dug or forked over, thus breaking up the subsoil without bringing it to the surface. Mark out the next trench, taking care that it is the same



THE RESULTS OF INCORRECT AND CORRECT METHODS OF DIGGING OVER LAND.

THE WRONG WAY.

THE RIGHT WAY.

Digitized by Google

width as the first, and then place the surface spit on top of the subsoil in the first trench; and treat each successive trench in a similar manner.

In order that a heavy subsoil may be broken up and become in a fit condition for bringing to the surface, farmyard manure or other decayed material should be worked in. Here I should like to point out that at no time should garden refuse be burned—except when diseased—for if this is collected and rotted it provides the best material for digging into a heavy subsoil, while farmyard manure may be spread between the subsoil and the surface spit.

After a heavy soil has been worked to a depth of two spades for a number of years trenching may be practised, as by such time the two spits have become almost equal in fertility. Such a condition is found in many old gardens, where the soil is of a light workable nature to at least the depth of 2ft.

The rougher a very heavy soil is turned over the better. The best method to accomplish this is to set it up in parallel ridges and thus expose a greater surface to the weather.

Sometimes a soil becomes "sick" to almost any crop, and when this occurs it is best to trench, and afterwards apply a good dusting of lime to the surface and allow it to remain until breaking down in the spring. Many of our gardens are deficient in lime, and this should be added, as it improves the fertility and tilth of the soil and neutralises acid conditions.

A mistake often noticed in practice is that of removing too many stones from the garden. Stones help to keep the ground open and porous, therefore within limits allow them to remain.

It is well to remember that the spade is the most important tool in the garden, and so should be taken good care of and at no time put away without being cleaned and rubbed over with an oily rag. The advantages of a polished, well kept spade are, perhaps, only known to those who use it constantly.

In the foregoing remarks I have tried to convey the importance of good digging and seasonable preparation of the soil, and a few of the advantages obtained from such. All cultivators should make a careful study of their soil and its proper treatment, for it is only by so doing that the best results can be obtained.

F. P. KNIGHT.

R. H. S. FORTNIGHTLY SHOW

DURING the last few horticultural shows one cannot have failed to have been impressed and struck by the standard of excellence reached by the numerous exhibitors despite the adverse weather conditions. But at long last these conditions have had their due effect in the distinct falling off of exhibitors at Vincent Square on Tuesday, 4th inst., on the occasion of the fortnightly show of the R.H.S. Many of the exhibits which were staged also showed clearly the rigours and vagaries of our British climate. No doubt, the National Chrysanthemum Society's Show on Thursday and Friday (of which a report will be found in this issue), accounted to some extent for the small number of exhibits and for the general lack of interest displayed. It is unfortunate when two shows come together in the one week, as the first one is always apt to suffer through preparations being made for the second. Nevertheless, one could not but be interested in a few of the exhibits on Tuesday last.

The commercial grower is now awakening to the increasing demand for shrubs, by placing all the latest varieties and species on show, allowing the public to gain a true impression of the plants. On Tuesday the most noteworthy collection of shrubs was that of Messrs. John Waterer, Sons and Crisp. It is well known how great an interest this firm has shown in the past in the raising of shrubs and trees, especially rhododendrons and also choice conifers. Their stand, however, included neither, the outstanding plant being the holly—present in numerous species and varieties. Innovations were plentiful, which, naturally, added a decided interest to the exhibit. One of the new arrivals from China was there in Ilex Pernyii, a very handsome evergreen of compact habit. The tinting in the leaves was noticeable, changing from a pale to a very dark green, the leaves being about 1½ins. long. The brilliant red berries are borne below the leaves and are thus hidden from sight. It is rather a difficult species to fruit really well, but when it does so it is a decided acquisition to the autumn shrubbery border. Another distinct and rare Chinese holly was I. Fargesi, with long, narrow, opaque foliage, giving the plant a decidedly graceful appearance. Many fine standard hollies, such as Waterer's Golden Queen, Silver Queen, etc., were on view. Several of these are particularly handsome trees. One worthy of notice was the yellow-berried variety, carrying masses of yellow berries. Many others were present with tinted leaves, variegated leaves, etc., and they all contributed to make the stand a pleasing one from the onlookers' point of view. Interspersed among the hollies were well fruited specimens of Skimmia japonica, which gives such charming effects in the rock garden. As an edging to the exhibit Veronica Hectori was utilised—the most whip-cord like of all the New Zealand veronicas.

The firm of Dobbie and Co. have long been famed throughout this country and abroad for the high quality of their potatoes, and the excellent results which the firm attain in the raising of good crops from their own Scotch seed were manifest on Tuesday, 4th inst., by the splendid exhibit on view. Nowadays the potato is open to so many diseases, both insect and fungoid, that the constitution of certain varieties becomes much weakened, so that after a run of a few years in cultivation a certain variety becomes exhausted and dies out. For seed purposes infected stocks are of no use whatever, giving a very poor yield. The reason, no doubt, why Messrs. Dobbies' meet with such phenomenal success in raising seed is because of the position of their trial grounds. Climatic and topographical conditions are such as to reduce disease to a minimum and the stocks supplied are as healthy and robust as possible. Non-immune varieties are being largely experimented with these days and already a few varieties have been found which, as well as being free from attacks of diseases, are excellent and heavy croppers. New potatoes are always wanted as early in the season as possible, and early varieties, such as Arran Rose, a kidney-shaped variety, and Resistant Snowdrop, will be found suitable. As second earlies and main crop varieties, Arran Comrade, Great Scot and King Edward VII will give good results, while for late varieties, Kerr's Pink, Arran Chief and Golden Wonder all old standing and popular varieties, cannot be beaten.

Messrs. Stuart Low and Co. were again to the fore with a tastefully arranged stand of their perpetual-flowering carnations. This firm has built up a well established reputation as carnation specialists, largely due to their untiring energy in trying to place on the market really excellent all-round varieties. On their stand were to be found notable kinds, such as White Pearl, which undoubtedly is one of the finest of all whites in commerce; Lord Lambourne, a gorgeous scarlet in colour, which will give excellent results and effects in the garden; Eileen Low, a perfect salmon pink in colour; Reginald Cory, a large flower of a shade of cerise; Duchess of York, a colour of rose spotted with red. These serve as an example of the breadth of choice which confronts the buyer. All forms and shades are there suitable for every whim and every garden.

The high standard of perfection which the chrysanthemum has now attained, its brilliant colours, variety of form and the fact that it blooms at a time when other flowers are scarce, make it one of the most appreciated of all flowers. This perfection has been reached by selection, crossing and great perseverance of many growers for a period of over a hundred years. The great range of sizes, varying from the minute pompon form to the huge heads of the Japanese type and the countless varieties which have been introduced are almost incredible. These features were well displayed by Messrs. H. J. Jones, whose exhibit was outstanding. Only extreme care, intensive cultivation and fine quality of stock could have produced flowers of such size and colouring.

From a colour point of view the yellows were superior, being of a clear and luminous tone. An excellent combination was that of the incurved variety Buttercup and Jean Pattison, a smaller example of the decorative type; the two distinct forms made a pleasing contrast; the coppery-orange of Jean Pattison showing off to great advantage the huge yellow head of Buttercup. Two more which blended well were George Carpenter, a shaded orange of excellent form, and In Memoriam, a beautiful crimson with a velvety texture. Both were introduced during this spring.

It is no easy matter to select from the Japanese varieties suitable for exhibition a few representative ones, for all of them were of equal merit, but perhaps the most striking was Mrs. J. Monro, Junr., a deep crimson; Mrs. G. Drabble, a white; Princess Mary and Wm. Ridby, both yellow, were of good form and exceptionally large.

As a contrast to the somewhat heavy Japanese varieties were the singles; Miss Joyce Moore, a bright crimson, being one of the best. Phyllis Cooper, a deep golden yellow, and Sandown Radiance, a chestnut crimson, make a splendid addition to any collection.

Other exhibitors are as follow:

Begonias.—Mrs. Sofer Whitburn and Stuart Low and Co.

Carnations.—Allwood Bros., C. Engelmann and Stuart Low and Co.

Chrysanthemums.—Godfrey and Son, K. Luxford and F. G. Wood.

Foliage Plants.—Stuart Low and Co.

Fruit.—Sir Charles Nall-Cain, Bt.

Hardy Ferns.—W. B. Cranfield, Esq.

Hardy Plants.—B. Ladhams, Limited, Reamsbottom and Co., L. R. Russell, Limited, and Carter and Co.

Landscape.—Percy S. Cane and K. and E. Hopkins.

Digitized by Google

Roses.—J. H. Pemberton.
Topiary.—John Klinkert.
Vegetables.—Barr and Sons.
Violets.—J. Kettle, Baldwin Pinney.
Artists.—Edith H. Adie, Edith A. Andrews, Maude Angell, Marion Broom, Hilda M. Coley, Edith Fisher, Mrs. E. J. Lugard, Mrs. Henny Spencer, Winifred Walker, Ellen Warrington, A. F. Wilkinson.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

CHRYSANTHEMUM GORGEOUS.—This is an excellent single variety with a large yellow eye, from which slightly reflexed florets spread out. In colour it is a dark red. The flowers are borne well and the habit of the plant appears good. Shown by Godfrey and Son, Exmouth.

C. HARMONY.—This is a market variety, the blooms of which were of good shape and texture. In colour the flowers were bronzy-yellow borne on erect stems. It appears to be a variety which will have a future in front of it. Shown by H. Shoesmith, Guildford.

C. SALMON QUEEN.—Also a market variety. The colour, at least to us, was not attractive, being of a lightish brown, with a light yellow centre. Shown by H. Shoesmith, Guildford.

CARNATION LADY HINDLIP.—This is still another variety of a perpetual-flowering carnation. It is a mixed colour, whitish ground speckled with pink or cerise. Shown by Stuart Low and Co.

CHRYSANTHEMUM MR. J. SLACK.—A handsome Japanese variety with blooms about 9ins. across.

C. THOMAS W. POCKETT.—This is also another Japanese variety with large blooms, fully 9ins. across. In colour it is of a satiny pink. The habit appears good, the flowers being carried on an erect stem.

C. SHEILA.—This is an exceedingly good single variety. In colour it is dark red to maroon, with the florets spreading outwards from a yellow eye. Above three plants were shown by Messrs. Keith Luxford, Harlow, Essex.

DIANELLA TASMANICA.—A representative of the lily family from Australia, where it grows to a height of 4ft. to 5ft. The leaves are long and linear and form a rosette. Flowers and the fruits are borne in a loose panicle. The plant bears great numbers of pretty blue berries which remain attractive for several weeks and form the chief charm of the plant. Shown by Colonel Stephenson Clarke, Borne Hill, Cuckfield, Sussex.

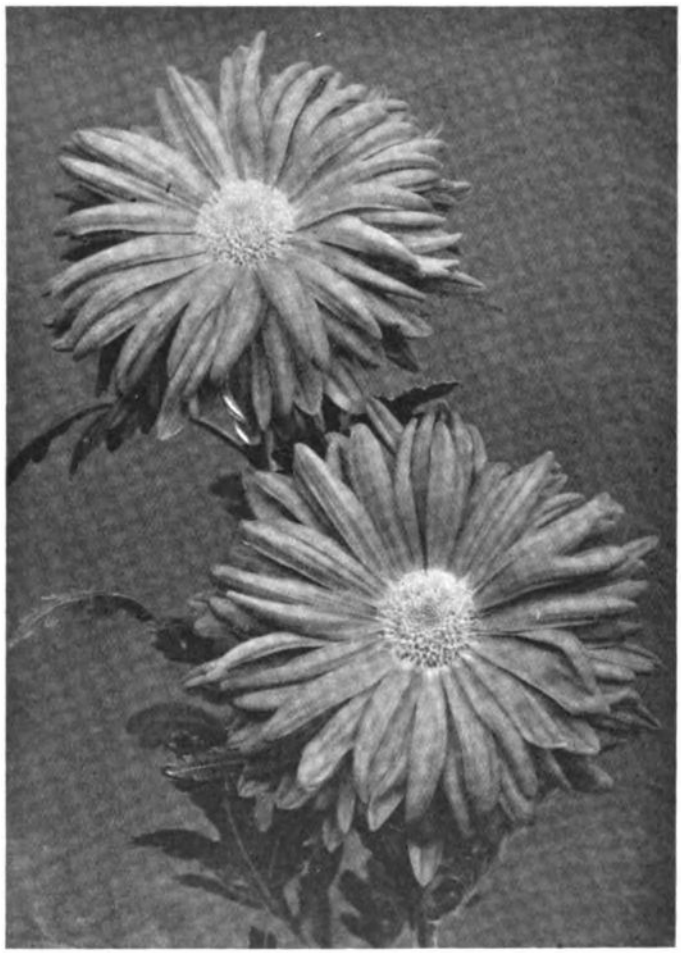
BILLARDIERA LONGIFLORA.—Another shrubby representative from Australia, where there are six to eight species. These are undershrubs with twining branches and terminal flowers, suitable for growing under glass. The leaves are showy, but the chief charm of the plant lies in the violet-blue succulent fruits which are carried in great numbers. Shown by Colonel Stephenson Clarke.

LONICERA LIGUSTRINA YUNNANENSIS.—This species is exceptionally like L. nitida and should make an excellent hedge plant with its close, compact habit of growth. It bears a heavy crop of round dark blue berries in groups close to the main stem, where they are somewhat hidden by the foliage. Shown by Colonel Stephenson Clarke.

COTONEASTER GLAUCOPHYLLA (FRANCHET).—One of the large-leaved species bearing heavy crops of dull red berries. Shown by Charles Eley, East Bergholt Place, Suffolk.

POLYSTICHUM ANGULARE DIVISILOBUM.—One of the numerous varieties of the prickly shield fern. This variety, as its name implies, has divided and spreading fronds, which are rather curved. It is of a dull green in colour and is suitable, along with the other variety, for planting in shady nooks.

P. A. FALCATUM No. 1.—The fronds in this variety are also much cut, but are flattened and spreading, giving the fern a pleasing habit. Shown by W. B. Cranfield, East Lodge, Enfield.



CHRYSANTHEMUM SHEILA.

ORCHIDS.

LÆLIO-CATTLEYA LUSTRISSIMA, WESTONBIRT VAR. (C. Warscewiczii × L.-C. Lustre).—A grand hybrid bearing a couple of large flowers, nearly 8ins. in width, of rose colour, the roundly formed labellum purple, heavily tinged with crimson. First-class certificate. Shown by Lieutenant-Colonel Sir George Holford, K.C.V.O., Westonbirt, Tetbury, Gloucester.

VUYLSTEKEARA ASPASIA VAR. POLYSTICTA (Odontioda Charlesworthii × Miltonia Charlesworthii).—The spike carried six flowers, in formation resembling the latter parent, sepals and petals crimson-red, labellum rose tinted, blotched at the base with crimson-red and profusely spotted with similar colour. First-class certificate. Shown by Messrs. Charlesworth and Co., Haywards Heath.

CATTLEYA WEMBLEY (Peetersii × Alexandra).—A large flower, remarkable for its brilliant coloration. Sepals and petals light crimson-rose, labellum ruby-crimson, and with an orange throat. Award of merit. Shown by Messrs. Flory and Black, Slough.

LÆLIO-CATTLEYA HASSALLII ALBA VAR. SUPREME (L.-C. Britannia × C. Warscewiczii var. F. M. Beyrodt).—The two large flowers have pure white sepals and petals, the labellum heavily stained with purple. Award of merit. Shown by Messrs. J. and A. McBean, Cooksbridge, Sussex.

MILTONIA BEAU BRUMMEL VAR. AUREOLE (M. Bleuana × M. Venus).—The spike bore three flowers in which the petals were flushed with deep rose, the flatly displayed labellum prettily spotted with crimson. Award of merit. Shown by Messrs. Charlesworth and Co., Haywards Heath.

CORRESPONDENCE

SERVICE TREE OF FONTAINEBLEAU.

SIR,—I am often impressed with the beauty of Pyrus latifolia, whether grown in the pleasure grounds of estates or in the garden proper. It might readily be taken for a beam tree, though not the white beam tree, because the undersides of the leaves are grey, not white. The berries or fruits, however, are the most striking ornament of the tree, being large, orange yellow, or tinted with red, for it varies on different trees. The fruit is produced in great quantity, usually every year. I have in mind also a tree that was planted in a front garden and was heavily cut back. After a year or so it fruited again regularly on the young growth of the shortened branches. Occasionally the birds carry away the seeds and young trees spring up and fruit in suitable places on commons and in woods. The value of the tree is recognised on private estates the owners of which specialise in trees.—J. F.

CATALOGUE DESCRIPTIONS.

SIR,—The leading article in THE GARDEN of October 25th with respect to catalogue descriptions of plants opens a wide door. Many would-be purchasers would undoubtedly come to a decision if information as to the habits of plants, soil, etc., could be included in the price list. It is a question after all which affects the seller as much as the buyer. We shall be told that the cost of production of catalogues to-day prohibits their enlargement, but if, as we see, novelties can be given preferential treatment in the way of describing their merits, and their good qualities extolled, would it not be a paying proposition to lift from the realm of comparative obscurity many plants to-day—the names of which to the average gardener convey little or nothing—by inserting more about them? I think so. We shall in all probability be reminded that the enhanced

Digitized by Google

price of a novelty warrants its good points being enlarged upon. That may be so, but if it pays the distributor to do this when a plant makes its debut, why should it not also be remunerative to him to enlarge upon the merits of older plants, large stocks of which he may have in his possession, wasting their sweetness and beauty in the nursery year after year? "Lost for the want of proper advertising" might be writ against many a flower that once held high place, but unknown by present-day gardeners. I venture to say, if it were possible to have a bird's eye view of stocks in many nurseries which are not sold, we should come to the conclusion that one of the reasons was insufficient publicity. The concluding note in the leader referred to gives one food for thought. It is this, "After all, a plant is an article for sale." Precisely, and, if it has merit it is worth selling and therefore it is worth advertising well.—CLAREMONT.

SIR,—As an amateur gardener occupied throughout the year in the various branches of horticulture, I respond to your invitation to readers of THE GARDEN to express their views on this subject. I do so in defence of the nurseryman. I have purchased and have in cultivation some hundreds of plants all of which have been selected, finally, from catalogues issued by most of the best known nurserymen and specialists in different departments of horticultural interest. My experience thus arrived at is that plant descriptions, though it may be they are slight in some particulars, are not generally inadequate. I have found that nurserymen are most obliging in giving any desired information about the plants they sell or obtain for one. Your correspondent's complaint, formulated "with some heat" (which, by the way, is only useful in the hot-house or conservatory, temperamental heat being quite at variance with the peaceful occupation of plant cultivation) seems to be based—first, on very exacting criticism of the catalogues; and, secondly, to arise in circumstances over which neither he nor anyone else had any control. Your editorial article states that the primulas, which have caused the outburst in referring the matter to your valuable consideration, are *rare*. If so, why should your correspondent expect to find in any (or every) nurseryman's catalogue all the specific information he desires? As is said, there are books to refer to, and has your correspondent no friends whose experience of the particular kind he desires might be added to his own? If a personal statement is allowable, I may say that if I wish to get a plant—rare or other—I find part of the interest in it in informing myself as to its requirements of the kind set forth in your note before purchasing it. If I am fortunate enough to have rare ones sent to me, it is my custom to abstain from railing at nurserymen's catalogues generally. It is possible to deal quite successfully with plants sent from the Continent if accompanied with a note from the sender describing the situation and soil. It is a little difficult to realise what is comprised in the terms "tiny" plants. It may be that such description is confined to the various species and varieties of plants (bulbous as well as other) which are commonly known as rock or alpine plants. If so, or if not, what is the exact size beyond which the plants your correspondent is searching for must not grow? If I may be permitted to comment upon your own illustration of an adequate description, it is only to say that a nurseryman's catalogue on such a plan would become a volume. Your remark that the more an *article* is described in a catalogue the more are sold is suggestive of Harrods or Selfridge's stores. Plants being living things, possess the interest of requiring knowledge, skill and experience—greatly contributed to in your valuable paper—to keep them alive by cultivation. I do not doubt that Harrods or Selfridge's, on receiving exact measurements of your correspondent's garden and the size of the "tiny" plants he wants, would do the whole business for him; but—he would not become a gardener and would miss all the pleasure of being a cool and studious one.—A. J. H., *Tunbridge Wells*.

[A fair hit.—ED.]

NOMOCHARIS PARDANTHINA IN A PERTHSHIRE GARDEN.

LABELS AND LABELLING.

SIR,—Labels, I consider, are absolutely necessary in a garden, whether it be a rock garden, herbaceous border or fruit garden. I index all plants bought in or given me and label them temporarily with wood labels and when time permits write permanent zinc ones. I quite agree with your valuable reminder on page 692 and those of your contributors, W. Linders Lea and "Burton-on-Trent." No one, however good his memory, can remember where each plant is growing. How many readers have visited a friend's garden and "spotted" a treasure which he had not seen before and if the grower is asked the name, many a time he cannot for the life of him tell you off hand. Had a label been there, although only to prog his memory, one could then take note of it and when the season for planting comes round order for oneself. I was one who had the privilege of spending two days at the Imperial Fruit Show at Birmingham last week and how disappointing from an educational point of view, owing to many of the varieties of apples not being named. Many certainly were named and the name of the variety prominently fixed on to the box or boxes, but again quite a number of varieties of fruits were not named. Not only were our British growers at fault, those from the Dominions overseas were equally as bad.—GEO. STUART, *Edinburgh*.

PRIMULA VINCÆFLORA.

SIR,—I was much interested in reading your article in THE GARDEN of October 4th on Curious Relatives of Primulas, with photographs of Omphalogramma vincæflora. I may say I have grown and flowered these primulas in my garden in Glendevon, Perthshire for the last six years. Seedlings I raised from home-saved seed flowered this summer for the first time, and I find it takes from three to four years to flower this primula from seed.

A RARE PRIMULA, P. VINCÆFLORA.

My plants are growing in damp peaty soil facing north. Six of my seedlings flowered this summer and three of them set good capsules of seed. These plants have no protection whatever and stand the winter in Perthshire without any pane of glass over them. I have Nomocharis pardanthina growing in the same situation and find it does well. The Nomocharis I have planted 6ins. deep, and neither it nor Primula vincæflora shows any sign of growth until about the second week in May, therefore escaping any spring frost.

I enclose photographs showing Primula vincæflora and Nomocharis pardanthina in flower in my garden during the past summer.—A. H., *Perthshire*.

THE MORAINE OR SCREE GARDEN.

SIR,—I should like to thank Mr. Clarence Elliott for his most instructive and illuminating article on page 730 on this subject. He has demonstrated to us clearly, how it is possible to use an existing rock garden—not necessarily of great dimensions—and to convert it into a scree. It came very opportunely for me, as at the time I was engaged trying to effect a transformation with a small rock garden of my own, and the hints he has thrown out have been specially valuable. Most fully do I appreciate what he says about incorporating plenty of broken stone, etc., and to "go easy with soil." I have been using broken limestone for my purpose among some of the campanulas mentioned by him, Gentiana verna, Saxifraga Burseriana, S. oppositifolia, and lastly, that specially close creeping diminutive plant with foliage so white in summer, Raoulia australis, which appears to be so little known, and whose acquaintance I made only a few months ago. Two points worthy of reiterating in Mr. Elliott's article are the ensuring of good drainage, and the using of material for the scree that may be procured handy, such as sandstone, limestone or even granite chippings. The term rock garden conveys to some people a very large, elaborate structure—a quite erroneous idea—but in the case of a scree no one need be deterred in making one on the lines suggested by him, and it is easy to add to as time goes on, if it is desired to do so.—W. L. L.

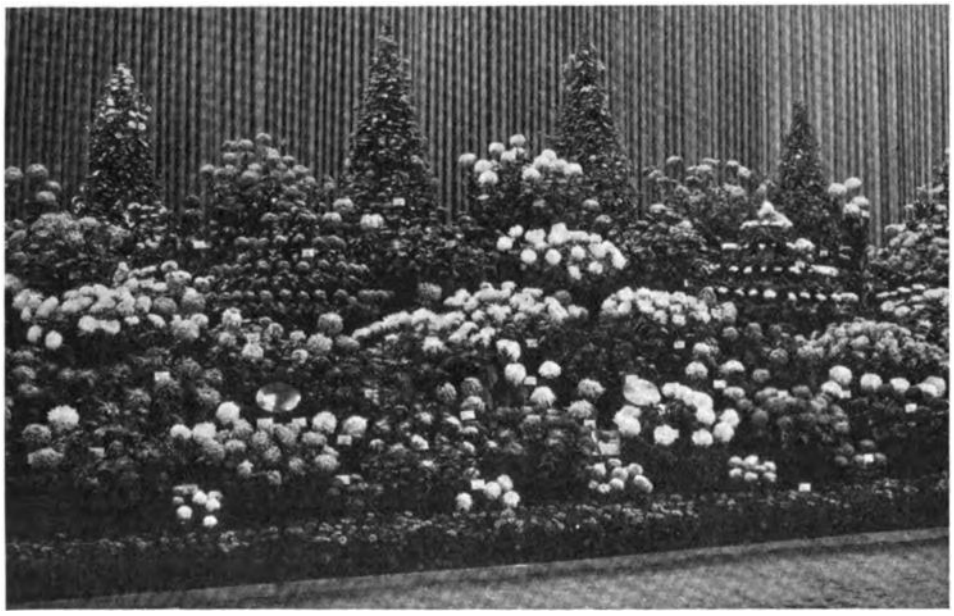
The AUTUMN HORTICULTURAL SHOW in PARIS

FINE, mild weather favoured the autumn show of the French Horticultural Society which took place in Paris from October 24th to November 2nd last. Unfortunately, the ordinary ground, at the Cours la Reine, was not available, owing to preparations being made there for next year's International Decorative Arts Exhibition, and the organisers had to be satisfied with a rather uncomfortable space near the Porte Maillot, where the general effect of the show suffered to some extent. Individual exhibits, however, were, as usual, quite interesting, and the show was an important one.

Needless to say, the chrysanthemums were, at this time of the year, much to the fore, particularly in the big Japanese varieties with very large flowers. These plants probably totalled a good half of the show. Next in importance came fruit, particularly apples and pears, fruit trees of all kinds, dahlias, roses, carnations, orchids, begonias, etc.



MESSRS. VILMORIN ANDRIEUX'S WELL ARRANGED EXHIBIT OF CHRYSANTHEMUMS.

Messrs. Vilmorin - Andrieux of Paris scored the success of the show. This old and well known firm had an enormous exhibit of chrysanthemums of all sizes and classes, from the large and elaborate pyramid with several hundreds of flowers to showy uniflorous plants, dwarf market varieties, singles, pompons, etc. A good number of novelties made the exhibit all the more interesting. The same firm had a huge stand of vegetables of the very best quality, some 75ft. by 20ft., where practically all autumn and winter kitchen garden produce could be seen.

Next in interest was the well arranged stand of Messrs. Cayeux and Le Clerc of Paris, who had a most up-to-date collection of dahlias, wonderful varieties of recent years in which the firm has specialised so much. Among the cream of the varieties may be mentioned: Mme. Victor Cayeux, Mme. Dresselhuys, Salmonea, Mme. Berthe Daru, Jean Chazot, De Rose, Simone Laurent, Orange King, Louise Aureau, King Harold, Mme. Wurfbain, etc. This exhibit was only made possible at this time of the year by the complete absence of frost up to the present in France.

Mr. G. Truffaut of Versailles was, as usual, a great exhibitor of chrysanthemums, uniflorous plants with large heads, grouped attractively in big masses of one variety. All standard commercial Japanese varieties—Mrs. Gilbert Drabble, Mme. Paquin, R. C. Pulling, Captain Fox, Ami Paul Labbé, Salonica, etc.—were very finely represented. A lovely semi-single white of great substance, Catherine Rambourg, was freely and successfully used.

Mme. Vve. Martin of Champigny has specialised for years in novelties and showed eight or ten seedlings, novelties for the year, among them Canari is one of the deepest yellows in existence, with medium sized flowers; Sir du Président Labbé, a fine red; Veronique, a large rosy lilac.

Singles were the speciality of M. Férard of Paris, who scored several awards in that class as well as in the class of pompons. Orléanais, yellow; Boetie, red, etc., were bright in that important stand.

Orchids came in fair numbers, but unfortunately the tent that contained them was rather too small both for the plants and for the public, and very few plants could be seen to full advantage. The prize for the best flower of the show went to Brasso-Cattleya Mme. Bokanowski, a fine deep pink flower, labellum deeper tinted.

Hardy pants and alpines were very few, owing to the late season and also to the fact that these plants are perhaps not so suited to the French climate as they are in England. MM. Férard and Thiebaut, both of Paris, had small natural rock gardens.

Mistletoe came as a surprise in a flower show; it was shown by Mr. Graef of Orléans, who had established small bunches of it on, presumably, apple tree stocks—standards 2ft. to 3ft. high and bunches 1ft. or so across. It is difficult to know whether the plants will continue to grow satisfactorily on a leafless stock.

Near the entrance were two very important stands of fruit, that of Messrs. Croux and Son of Chatenay, and Messrs. Nomblot-Bruneau of Bourg-la-Reine, who each grouped 500 to 600 dishes in the standard and amateur varieties. These two stands attracted much attention. Messrs. Moser and Sons of Versailles had also an interesting and important display with many rare varieties of pears and apples.

Vegetables, besides the remarkable stand of Messrs. Vilmorin-Andrieux already mentioned, were also shown by M. Truffaut of Versailles, who had, among other items of interest, fine collections of potatoes and leeks; and by the Horticultural School of Igny, a philanthropic undertaking which is a school for gardeners and orchardists. In two stands could be seen the curious Siamese or Malabar gourd mentioned in THE GARDEN some time ago.

Several large firms exhibited fruit trees, an important matter in French gardening. The trees were all full sized and models of good training. Croux and Son of Chatenay, Nomblot-Bruneau of Bourg-la-Reine, Moser and Sons of Versailles, Carnet of Mitry-Clayes, and Chauffour of Versailles, had numerous specimens trained as espaliers, pyramids, cones, vases, cordons, etc., 8ft. to 12ft. high; also many fancy shapes. This part of the show covered a vast area outside and attracted many visitors.

A *salon* of painting applied to flowers and fruits was attached to the show and quite a number of interesting works of art were shown, including "models" perfectly made, a speciality of Mr. Theveny of Paris, who has made a name for himself in that line for many years past.—C. L., *Paris*.

ROSA FARGESI.

THIS beautiful rose has loose and gracefully arching growths laden with conspicuously brilliant red bottle-shaped fruits of unusual size. It is of vigorous growth, resembling in this respect the better known R. Moyesi, to which species it is closely allied. By reason of its constitution it quickly forms a large bush, and throughout the month of June, when decked with large single pink flowers, is one of the handsomest of all wild roses.

A little careful thinning of the old wood is all it requires in the way of attention, while pruning as it is generally understood should never be practised, for it is a shrub capable of attaining 12ft. in height, with a fine and elegant spread of branches.

Seeds gathered during October, 1923, from this rose and sown immediately in pans of sandy soil—in cold frames for the winter—germinated with the greatest freedom from the beginning of March onwards and are now plants a foot in height. E. M.

SIMPLE GARDENING

SOWING BROAD BEANS AND PEAS.

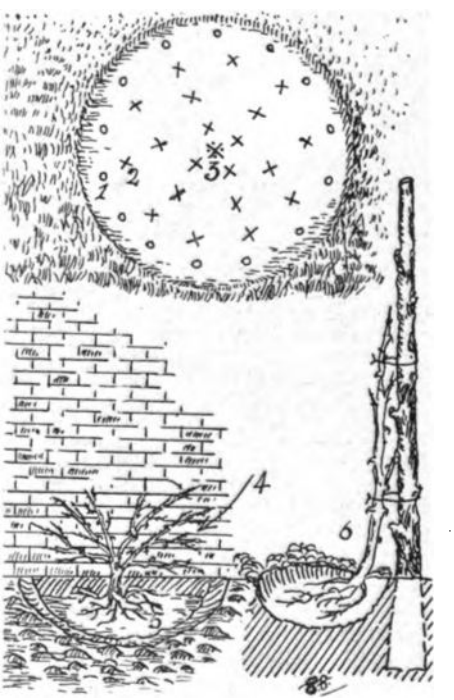
SOWING seeds and harvesting crops of one kind or another take up the time and demand the close attention of the gardener throughout the year. The true lover of a garden is never at a loss to find something to do. Just now we are busy sowing seeds of broad beans and peas in the open borders where the soil is not too wet. In low-lying gardens and where the soil is tenacious, special treatment should be given or the sowing deferred till next spring. I prefer single rows of broad beans 1ft. apart in the case of very dwarf varieties and 18ins. in the case of others. Beck's Green Gem is a good one, for the small garden especially, and Seville Giant Longpod, I find, a good one for general use. Now, where ordinary soils obtain they should be deeply dug and enriched with rotted manure only. Treading on the soil should be avoided as much as possible and the surface portion left in a rough state—at any rate it should not be raked down. Where the soil is heavy, the rows of seeds should be covered with dry sand, soil, wood ashes or even sifted coal ashes, and the surface, after sowing is completed, should be freely sprinkled with ashes. The same treatment applies to peas, but the most sheltered positions should be chosen for them. Only round-seeded varieties should be sown as the marrow-fats would rot in the cold soil. Damp the seeds and roll them in red lead as a protection from rats and mice, also birds.

SPIRÆAS FOR FORCING.

The spiræa is doubly useful when grown under glass; its flowers are pure, feathery and borne freely and, further, the foliage not only acts as a fitting setting to them, but helps considerably to furnish the greenhouse or conservatory. Unlike many kinds of plants that are to be subjected to a forcing temperature, spiræas may be potted and forced forthwith. But there should be no undue hurry in getting the clumps potted. The crowns, from which the main leaves and the flower-stems grow, must be matured; the old leaf-stalks should be allowed to ripen naturally and almost entirely before the roots are disturbed. Many leaf-stalks, however, remain rather firmly adhering to the crowns till late in winter, and their presence should not be regarded as any hindrance to the work of potting after the end of November. Such stalks should not be forcibly removed; the disturbance of the roots owing to the necessary potting will have the effect of loosening these stalks, which will soon fall away naturally. Large pots are not required; those that will nicely contain the clump and a very small quantity of sifted soil will do. The soil should be rich. One crock in each pot will answer for drainage. When potted keep them in the open air, exposing the crowns to frost, but protecting the pots from it by plunging them in leaves, ashes or litter. When forcing the plants, maintain plenty of moisture at the roots and in the atmosphere. Spiræa japonica, white, and the pink variety are easily forced.

PLANTING ROSES.

No doubt many readers of THE GARDEN made good resolutions about planting when they visited the shows and inspected the lovely blooms staged. I know that this was true in my own district and this is but one case out of hundreds. Like fruit trees, roses are all the better for being planted in the autumn, but even then they are better still if planted while the soil is fairly dry. Before a single plant is put in, the soil should be deeply dug and rotted manure only mixed with the top portion. The subsoil should be well broken up.



No. 1 shows dwarf-growing varieties; No. 2, bushes; and No. 3, a central standard or half-standard. This method applies to beds of distinct varieties or those filled with one sort only. No. 4 shows how to dispose the branches on a wall; and No. 5, the roots; while No. 6 shows how pillar, arbour and similar plants should be planted and tied temporarily. The roots must be neatly arranged to grow away from the underground portion of the post.

HOW TO KEEP RIPE GRAPES IN WINTER.

It frequently happens that a cultivator of grapes is unable to retain the bunches on the vines after the end of November. Some other means must be devised, then, to keep the berries fresh as long as possible. Where grape rooms are provided there is not much difficulty; in their absence we must devise a substitute. Perhaps a large dry cupboard can be used in a dry cool building and arrangements can be made to ensure ventilation at will. Bottles holding three half-pints should be filled with clean water and into each one a few lumps of charcoal should be placed. The bottles should be fixed at an angle of 45°, with a clear space below the necks for the bunches to hang free. The bottles must be fixed—secured to their rests. Before cutting the bunches examine them carefully and remove all unsound berries. The stems below the bunches should be cut long enough to allow free insertion in the bottles; the stems above the bunches need not be left more than 3ins. long. The stems should be severed with a sharp knife to leave open the sap vessels. A change of water in the bottles will be necessary every fortnight at least, and ventilation of the store should be such as to prevent any moisture settling for long on the berries.

SHRUBBERIES.

Even in one's own case one finds it difficult to keep the shrubbery as neat and as interesting as one wishes it to be. When first a shrubbery is formed, how careful of every individual plant the owner is, and this care extends over several years; then, with a few exceptions, neglect begins, the shrubbery is established and can take care of itself as it were. A mistaken idea. When shrubs overgrow into each other and are allowed to continue this growth for several years, two things must be done—severe pruning and the entire removal of spoiled plants. Hundreds of shrubberies are treated in this way year after year, and it is better that they should be than not receive any attention. My present object is to induce owners of young shrubberies closely to examine them now, and put right things found to be wrong. The work is not great if done annually. New shrubberies are being formed; there is ample evidence of this to be found all over the country. It is a good sign of revived interest in gardens. The permanent plants should be very carefully arranged in the new shrubbery. Plant them first, then those that are to fill, and in such a way that they will not interfere with the natural growth of the permanent specimens.

MUSHROOM CULTURE.

Those in cellars and sheds will begin to bear in March and continue until the end of June to yield crops; the beds in the greenhouse will fail about the middle of May because sudden rising temperatures will favour the attack of maggots. Of course, succession beds would be a means of prolonging the supply. Stable manure alone, or two-thirds of it to one-third of tree leaves, should be used. All manure should be spread out thinly and frequently turned in a shed to get rid of rank gas. Firm beds are essential. Lumps of spawn should be buried 2ins. deep; a surface covering of fresh soil 1in. deep and a thick covering of clean straw are other essentials. Complete darkness and even temperature must be secured. It is well to maintain a fairly moist atmosphere, but do not directly water the bed itself.

GEORGE GARNER.

NOTES FROM CONTRIBUTORS

ATTRACTIVE ANTIRRHINUMS.

WE set out in the flower beds about the end of May young plants of Buff Beauty and Orange King antirrhinums, both intermediate varieties. The seed of each was sown on the same day in February and throughout the plants received the same treatment.

Buff Beauty, "a new and charming variety with soft pinkish buff self-coloured flowers, the most attractive of all the Buff Antirrhinums," has certainly made a fine display throughout August and well into September. Orange King, a glowing scarlet-orange, was a month later in making a show, consequently we are being favoured even at this late date—end of October—with a good show of rich and warm coloured flowers.—DAVID ARMSTRONG.

FOUR FINE ROSES.

THE present is admittedly the proper period of the year to plant roses, and those who desire to remove, re-plant or to form new beds or borders should embrace every opportunity to get on with the work. If the soil is poor a fair quantity of farmyard manure should be incorporated while the digging or trenching is going on. Where ground has not been turned over for many years trenching should be thoroughly and well done, as once the roses are set out, it is almost certain they will be left to grow in the same place for years, especially if they do well. Double digging might be recommended in places where the subsoil is barren and poor; this allows of the bottom layer of soil being turned over and mixed with manure or leaf-mould, but retained in the same position, while the richer and better surface soil is also well broken up, but kept on the top. Those who are fortunate to have access to plenty of turf from old pastureland have ideal material—when this has been stacked for a year or two before using—to mix with garden soil for growing roses. Well decayed manure, however, is not to be despised.

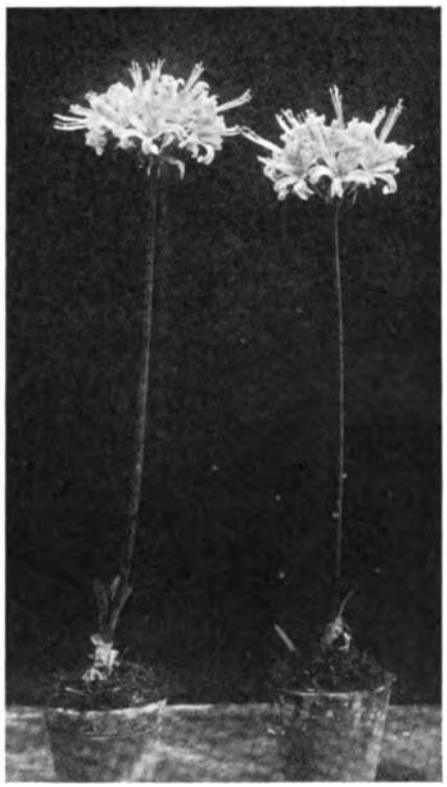
Last year, about the middle of November, we filled up a number of beds with roses. The varieties planted were Lady Alice Stanley, La France, Miss E. C. Van Rossen and Old Gold, all hybrid teas. It is interesting to state that all the plants have grown and flowered exceptionally well, not a single one having died. In the middle of July these varieties were gaily decked with flowers and they have bloomed more or less since then. Old Gold made a wonderful display throughout September and indeed well into October, so special mention must be made of its qualities: the beautiful soft apricot-coloured flowers, their fine shape when in bud, combined with such numbers produced—as many as sixteen buds and flowers having been borne on one stem and its short side shoots. Old Gold is therefore one of the very best bedding roses and seen when a pale September sun is shining it is a joy and charm to behold. The flowers are semi-double, and no doubt this is a quality *par excellence* in a variety for a wet and almost sunless season.

The flowers of Miss E. C. Van Rossen at a certain stage are delightful to the eye, but have a fault! Shall we keep it dark? No. The flower heads—at least a number of them—bend down and hide their faces. "This rose is the result of a cross between Leuchtfeuer and Red Letter Day," and the colour is described as dark velvety red.

Lady Alice Stanley and La France produce large blooms of good substance, which suffer sadly in a wet summer, the colour of the former is "coral rose, reverse silvery pink," while La France is described as silvery rose with pale lilac shading, both varieties are floriferous, vigorous and robust in constitution. La France, although a much older rose than any of the others mentioned, is still included and catalogued in "A select list of choice roses." This trying test of time surely proves the reliability of the fine old rose. However, no one need hesitate to plant and cultivate these four beautiful kinds. The foliage of each has, despite the wet, remained almost clear of mildew. About the end of June the ubiquitous green fly did get a footing on the tender shoots, but after a few sprayings the plants were relieved and have since remained clean and free from these insects.—DAVID ARMSTRONG.

NERINE MRS. W. R. LYSAGHT.

SOME four years ago we made several crosses among the nerines, and the subject of the illustration is the result of crossing N. Lady Lawrence and N. Mrs. H. J. Elwes. The former parent is more or less a crimson in colour, and the latter is a clear delicate shell-pink, while it ranks as



A FINE HYBRID NERINE.

one of the best nerines in commerce. The hybrid under notice is named N. Mrs. W. R. Lysaght; it is a beautiful shade of salmon-pink, exquisite in form, and possesses that delightful satiny sheen so characteristic of many of the nerines. It is an improvement upon the hybrid Mrs. H. J. Elwes.

Nerine Mrs. W. R. Lysaght was raised by me at Castleford, Chepstow, Gloucestershire, and it is named after the wife of the owner of Castleford, where so many rare and interesting plants find a genial home. A number of seedlings were raised, several of which have flowered, but the twain in the illustration were far the best and, moreover, absolutely identical. The photograph was taken by Mrs. Lysaght.—T. W. BRISCOE.

AUTUMN-FRUITING RASPBERRIES.

IN many private gardens the autumn-fruiting raspberries are held in high esteem, not only for culinary purposes, but for dessert, and thereby furnish an agreeable change to the usual run of dessert fruit at this season, viz., the end of October, and well into November if the weather is favourable.

It is a mistake to try to secure two crops in one year; if autumn fruits are desired the plants must be grown for this purpose.

Raspberries pay for generous treatment and when preparing the ground it should be dug deeply and some good farmyard manure and burnt rubbish incorporated as the operation proceeds. A suitable time for planting is November and December, and the roots should be planted in lines 5ft. or 6ft. apart, and a distance of 2ft. allowed between the roots. In the spring—say February or March—the autumn fruiters must be cut down to ground level, and when new growths appear they should be reduced to four or so of the strongest. The cutting down of the canes to ground level must be done each spring. Autumn-fruiting raspberries require frequent transplanting, and to make sure of a crop I transplant some annually, while others are never left more than two years without being lifted. When re-planting, select the suckers or young canes that appear a distance from the old root stock; they are more vigorous and, consequently, give better results.

The Hailsham raspberry or Hailsham Berry is one of the best; it produces a good crop of large fruits, rich crimson in colour, while the flavour is good and luscious. The comparatively new Raspberry Lloyd George is a perpetual-fruiting variety, and makes an excellent subject for autumn if treated as advised above. Another useful kind is November Abundance; while Belle de Fontenay and Queen Alexandra are also grown for autumn fruiting. If, however, one variety only is needed, then the Hailsham Berry should be chosen, with R. Lloyd George as runner-up.—T. W. BRISCOE.

PRATIAS.

TO make the acquaintance of any genus of plants through the medium of a comparatively poor species, yet one which is worthy of admiration, and then to go on to more attractive beauties, is an experience of much pleasure to most lovers of flowers. The converse is the case, however, when we meet first with one of the most charming species and, lured by its beauty, search for others of the race, and find them wanting in some of the loveliness of the first. With the writer the latter experience came among the pratias. He first made the acquaintance of the genus in the form of the lovely Pratia angulata, with its creeping carpet of small, oval, toothed, fleshy leaves and this carpet thickly ornamented with starry white flowers. A good plant of this is exceedingly charming, and it is a subject which one would fain commend to the alpinist. It comes, I believe, from New Zealand, whence it was introduced in 1879. It has also been known as Lobelia littoralis.

Of the other introduced species two at least are offered by the trade. These are P. arenaria and P. begoniæfolia, but one cannot conscientiously recommend them as superior or even equal to P. angulata. They are coarser, especially the former, and therefore less desirable. P. begoniæfolia is interesting on account of its coming from the Himalayas, but both can well be omitted from the rock garden without regret. So far as known to the writer, the yellow-flowered Pratia macrodon is not in commerce, but its description as a yellow-flowered pratia, forming tufts a foot across and with a profusion of fragrant yellow flowers, is sufficient to compel us to long to possess this native of the South Island of New Zealand. Whether it would please us should we ever be privileged to grow it is doubtful; but with such a beauty as P. angulata we need not greatly repine

SPECIAL AUTUMN OFFER

50 Spanish Iris, in lovely colours, given free with every order of 20/-. 100 with £2 orders, etc.

A FEW CHOICE SHRUBS FOR EARLY PLANTING.

Rhododendrons (named), all colours, 3/- and 3/6 each. 5,000 Clematis, Jackmanii, Woking Belle, Gipsy Queen, Montana (white and pink), Duchess of Edinburgh, 2/6 each, 24/-doz Lavender (Old English) and Cotton Lavender, 6d. and 9d. each (fine for edging). Flowering Cherry (Bush), 3/6 and 4/-. Bush Lilac, red or white, 9d. each. Buddleia variabilis 3/6 each. Yellow Broom, 3/6 each (large plants, 3-4 ft.). Veronica, 6d. and 9d. each. Euonymus, golden and green, 6d. and 9d. Snowberry, 6d. each, 4/6 doz. Southernwood, 6d. Ribes (flowering Currant), 9d. and 1/-. Golden Elder, 6d. and 9d. Hydrangea paniculata, 1/- each. Scarlet Willow, 6d. Honeysuckle (scented variety), 2/-. Wistaria, (Mauve), 2/6 each. Prunus Triloba, lovely pink early-flowering shrub, 3/6. Cotoneaster 1/-. Bamboos, 1/-, fine clumps. Genista (Broom), fine colours, named varieties, 2/-. Mountain Ash (young standards), 1/- each. Magnolia, 4-5 ft., a few specimens only, 7/6.

100 Darwin Tulips 7/6

100 Mixed Bulbs (Daffodils, Hyacinths, Tulips, Snowdrops, Crocus, etc.) 4/6

100 Scented Daffodils and Narcissus (10 favourite varieties, named) .. 8/6

All Carriage Paid.

Thousands of others to offer. Send for List.

20,000 SPLENDID ENGLISH FRUIT TREES

Standards, fine tall specimens, 6/6 and 7/6 each.
Apples, Pears, Plums, Cherries (Bush and Cordon) 2 to 3 years at 2/6 and 3/- each; 3 to 4 years, 3/6 and 4/- each.
Splendid specimens, 5 years, at 5/6 each.
Special Cordon Pears, 2 to 3 years.
Fertility.—These trees, standing 3 to 4ft. high, have now 20-30 Pears on every specimen. You must grow these.
Order early as stock is limited.
Apples.—Cox's Orange, Bramley's, Worcester Pearmain, Lane's Prince Albert, Stirling Castle, Warner's King, Ellison's Orange, King Pippin, James Grieve, etc.
Pears.—A splendid lot. William's, Fertility, Buerre Superfine, Jargonelle, Clapp's Favourite, Marie Louise, Pitmaston Duchess.

Plums.—Victoria, Belle de Louvain, Pond's Seedling Greengage, etc. All fine trees.
Cherries.—Gov. Wood, White Heart, Black Heart, Elton's Early, Biggareau, etc.
Red and Black Currants.—3/6, 4/6 and 6/- doz.
Raspberries, 1/6 doz. **Strawberries,** 5/- 100.
Loganberries, 9d., 1/- and 1/6 each.
Hallshamberries, 4/6 and 6/- doz.
Rhubarb.—Daw's Early, Raby, Champagne, 9d. and 6d. per root.

SPECIAL OFFER ENGLISH STANDARD ROSES

For early orders only 2/6 each.
Daily Mail, Sunburst, Rayon d'Or, C. Testout, Killarney, Ophelia, G. Dickson, McArthur, Edu Meyer, Radiance, Red Star, Capt. Hayward, Lady Ashtown, Jules Grolez, Progres, J. Laing, Prince de Bulgarie, Ravary, etc., etc. All fine strong trees, and have now a good show of bloom.
Bulbs carriage paid.
Bush Roses, same varieties, 10/6 doz.
Ramblers. 1/3 each (all named).

Hedge Plants.—Evergreen Privet, 3ft., £2 per 100; 1½ to 2ft., 35/- per 100; 12ins., 20/- per 100. Common Privet, 2 to 3ft., 17/6 per 100. Quick, 1½ to 2ft., 20/- per 100.
Vines.—Black Hambro, 3/6 and 4/6 each.
Walnuts.—2/6 each.
Filbert and Kentish Cob Nuts.—2/6 each.

PERENNIAL PLANTS FOR EARLY PLANTING

Wallflowers, red, golden, crimson, yellow, 4 vars., 2/6 per 100, carriage paid. Fine Bushes, transplanted, 1/- per doz. **Pansies,** Giant French, 9d. per doz. **Violas,** 2/- per doz., mauve, yellow, purple. **3 Hollyhocks,** 6d. **2 Anchusas,** 6d. **4 Arabis,** double white, 6d. **2 Lupins,** 6d. **3 Polyanthus,** 6d. **6 Forget-me-Not,** 6d. **2 Geum** Mrs. Bradshaw, 6d. **4 Sweet Williams,** 6d. **Pampas Grass,** large clumps, 1/- and 1/6 each. **Pinks,** Mrs. Sinkins and Her Majesty, 2/- doz. **Iceland Poppies,** 1/- doz. **Carnations,** mixed, 2/- doz. **Christmas Roses,** 1/- and 1/6 each. **Lovely Phlox,** named, all colours, 12 for 7/6. **Iris germanica,** 2/6 doz. **Iris Kaempferi,** 5/6 doz.

HERBS

Sage, 6d. and 9d. **Thyme,** 6 for 6d. **Mint,** 6 for 6d.
Passion Flowers.—Blue and white, 1/6 each.
Lovely Pyrethrum.—Queen Mary, J. Kelway and Cerise Pink, 5/- doz.
Montbretia, 5/- 100. **Spanish Iris,** 5/- 100.

Tree Carnations.—Perpetual flowering, named, blooms, 2-3 ins. across. Splendid for potting up for cool greenhouse, will bloom continuously from Nov. to June, 1/- each, 10/6 doz.
Rock Plants, in about 12 varieties, 2/6 dos., named.
50 Cabbage Plants 6d. **50 Onions** 6d.

Please give Name and Address (Post and Rail).

All Trees and Plants sent as soon as ready. Kindly add extra carriage for Trees and Plants. All orders over 20/- carriage paid.

NETHER GREEN, SHEFFIELD

Google

Please mention THE GARDEN *when writing.*

This needs a sandy, well drained soil, with full drainage, but with plenty of water in summer. It is a good precaution to keep a plant or two in a frame, lest an occasional severe winter should prove too much for this charming little flower. It increases by division.—S. ARNOTT.

COLLINS' FLOWER, COLLINSIA BICOLOR.

HARDY annual flowers of North America are the collinsias, and of considerable beauty when grown in large masses, even though such masses are carpeting the earth beneath taller-growing plants.

Their culture is of the simplest, and all that is necessary is to prepare a plot of ground and scatter the seeds broadcast, thinly, for almost every seed will grow and the thinner they are sown the taller and more handsome will their whorled flower spikes rise.

Sow the seeds in September, March or April and thin out the plants to 3ins. or 4ins. apart as soon as they are large enough to handle.

There are at least eight distinct kinds of collinsias, and the plant here dealt with is probably the strongest of the group. Its flowers, which are produced in whorls or rings round the stem, are white and lilac, and if sown in September, which is really the best time to sow, are very effective during May, June and July.

C. grandiflora is another modest but extremely beautiful plant which responds to similar treatment and, rarely exceeding 1ft. in height, is very desirable for producing carpets of colour either in the flower or rock garden. The flowers are of a lovely blue and pink shade, and colonies of them clothing the soil beneath groups of early-flowering rose species form a pleasing setting to those charming graceful shrubs.—E. MARKHAM.

PLANTS FOR THE CONSERVATORY AND GREENHOUSE.

LOROPETALUM CHINENSE is a pretty and interesting plant. Even in the south and west it never seems to have been over satisfactory outdoors, but when grown in pots it makes a fine plant for the cool greenhouse. Good specimens in 6in. or 7in. pots are very effective when in flower, for its creamy white strap-like petals are very uncommon. This plant is deserving of more general cultivation. It is easily propagated by means of cuttings of half-ripened twiggy shoots inserted in pots of sandy soil and stood under a bell glass in a cool house. This plant grows quite well in a light loam, with the addition of a little leaf-soil and sand. The young plants should be potted on as they require it until they are in 6in. or 7in. pots. Perfectly cool treatment is essential during all stages of its cultivation. During the summer months the plants may stand out of doors in a cold frame. This shrub is a native of the Khasia Mountains and of China, and, although introduced in 1880, is by no means so common as it deserves to be.

NANDINA DOMESTICA.—Although this plant is hardy in sheltered situations in the south and west, it must generally be regarded as a cool greenhouse plant. Although it seldom produces its fruit in this country, it is deserving of more general cultivation for its elegant foliage and pretty white flowers. The young foliage is also beautifully tinted. It makes a pretty pot plant when well grown, but it is really seen at its best when planted out in a cool conservatory. This plant is propagated by means of half-ripened shoots inserted in sandy soil under a hand light.

PUNICA GRANATUM VAR. NANA.—This dwarf variety of the pomegranate is hardy on a warm wall in the south and west, and usually flowers much more freely than the type. It is a neat neat-growing plant, with sleneer twiggy shoots. It is surprising that it is not more generally grown in pots for the cool greenhouse, as it makes very neat free-flowering specimens in 6in. or 7in pots. It is easily propagated by means of half-ripened shoots inserted in pots of sandy soil, which should be allowed to stand under a bell glass in a cool greenhouse. In common with many plants of this class, propagation is much more successful if a stock plant is kept indoors, as cuttings taken outdoors are by no means easily rooted. The young plants should be potted on as required. They grow quite well in any good potting compost. The young plants should be pinched several times to lay a good foundation for the future plant. During the summer months the plants should stand outdoors in an open sunny position, as it is essential that the wood should be well ripened for the free production of flowers.

TIBOUCHINA SEMIDECANDRA.—This beautiful plant, known at various times as Pleroma macrantha and Lasiandra macanthra, has now been in flower for some time, and will continue in flower for at least another month or six weeks. Its large deep violet-purple flowers, some 5ins. in diameter, are produced very freely. This plant is seen at its best when planted out in a large conservatory, training the shoots on a back wall or trellis-work. When the plant has covered its allotted space the shoots should be pruned hard back early in the New Year. During the growing season the young growth should be trained in thinly. This plant is easily propagated by means of the young twiggy shoots during the spring months. These root readily in a close propagating case with slight bottom heat. This plant can be grown in small pots for the stage, or as large specimens in tubs or large pots.

For the stage good plants can be grown in 5in. or 6in. pots. The strong long jointed shoots should be pinched at every joint until fine bushy plants are produced. During August the plants should be allowed to stand out of doors in a cold frame, as it is necessary to get the wood well ripened. By growing on the young plants the following year, large specimens are quickly produced. When they have attained the desired size they should be pruned back every spring. As this is a strong-growing plant it is not necessary or desirable to keep old plants for any length of time. There used to be in cultivation a dwarf variety of this plant, known as floribundum, which produced its flowers on quite small plants, more or less all the year round. Needless to say, this variety was better suited for pot work than the stronger growing type. —J. COUTTS.

RARE PLANTS.

THE following plants are sought for by readers of THE GARDEN. They are rare in cultivation, and we are unable to trace them in trade catalogues. We should be glad if any readers who may know where they may be obtained, would communicate with us. In almost every case exchanges could be made.

THE GARDEN

VOL. LXXXVIII.—No. 2766 NOVEMBER 22, 1924

Price Threepence. Yearly Subscription, Inland, 17s. 4d.; Foreign, 17s. 4d. Registered at the General Post Office as a Newspaper and for Canadian Magazine Post.
Editorial Offices: 20, TAVISTOCK STREET, COVENT GARDEN, W.C.2. *Offices for Advertisements:* 6—11, SOUTHAMPTON STREET, STRAND, W.C.2.
Entered as Second-class Matter at the New York, N.Y., Post Office.

LUPINS

THE subject of our coloured cover in this issue is the lupin, one of the most popular of our herbaceous plants.

The history of the lupin is a little obscure, for different species were certainly grown by the Egyptians and after them by the Greeks and Romans as an article of food. Even at the present day the lupin is grown as a forage crop in Mediterranean regions, while the seeds are eaten after being soaked in water to remove the bitter flavour. The same is the case with the American species. In fact, in all sub-tropical regions it is used as an economic product. What is obscure is their introduction to other countries. They are spoken of as being grown in the Rhine Duchies during the sixteenth century, but their introduction into England was probably far later, and they certainly were not popular until the late eighteenth century.

They are so well known in our gardens at the present day that no description need be given, but they are certainly one of our most exotic-looking herbaceous plants. The new varieties are of every conceivable shade and tone. It is as well to point out that lupins when once established should be left alone, as they do not take kindly to moving. They are easily grown from seed and are propagated by division.

Our coloured cover in the Rose Number was much appreciated by our readers, one enthusiast going so far as to say that it was so realistic that he could actually smell their fragrance. It was one of the last coloured transparencies produced by the late R. A. Malby and is a model of what skilful colour work can accomplish. The original of the cover to this issue was produced by one of Mr. Malby's assistants, and I consider it to be as successful as the rose cover.

OLD HERBACEOUS FLOWERS

AT this time of herbaceous planting it is interesting to see which of the modern herbaceous flowers were found in old English gardens. It must not be imagined that garden flowers as mentioned in old English gardening books were anything approaching those of modern gardens. In almost every case they were ordinary wild flowers transferred from the field to the garden. There was little selection, no hybridisation, and cultivation as we know it was in its infancy. Dydymus Mountaine mentions the holyhoke in 1577 along with the garden poppy. The use of the word "garden" is interesting, as it is one of the first signs of differentiation between wild species and a garden form. About the same period the peony became very popular.

During Elizabethan and early Jacobean times the following plants were fashionable in knots and borders: wallflowers, the crown imperial, fritillarias, sweet williams, larkspurs and snapdragons. There is little doubt that the lily is the earliest of what might be called modern herbaceous flowers to be mentioned in connection with English gardening. Its beauty is extolled several times in Chaucer; this lily was obviously Lilium candidum, but in several early manuscripts it seems probable that the word lily refers to flag irises. It is a fascinating evening's ploy during the long winter evenings to read about the evolution of the modern garden and about the history of horticulture in England. The growth of our knowledge has been slow and sure, but there is still an enormous amount to learn. Running through all garden literature is that extreme love of flowers which is one of our greatest assets.

A GLUT OF FLOWERS

THERE is a glut of flowers at the present moment at Covent Garden. Chrysanthemums in every shape and size are by far the most popular. To me the giant exhibition-flowered forms are too grotesque and stiff for indoor decoration and do not compare with the pompons, but they last well in water, many of them a fortnight or more, which is an advantage. Most flowers in vases are the better for having the water changed every day, and this is particularly the case with chrysanthemums, for vegetable decay sets in quickly and the water soon becomes coloured and evil smelling. Another cheap flower is the narcissus from the Riviera, which has obviously arrived too early, and is in bad condition owing to the warm damp weather in the South of France. The price varies from 4s. to 8s. for 48 bunches, a price which also is perhaps uneconomic for the grower. Two years ago the price was £2 for the same number of bunches. Every flower has its correct season in the market, and both the consumer and the salesman show their disapproval of inopportune arrivals. The present time is devoted to chrysanthemums.

AN OLD ENGLISH FLOWER

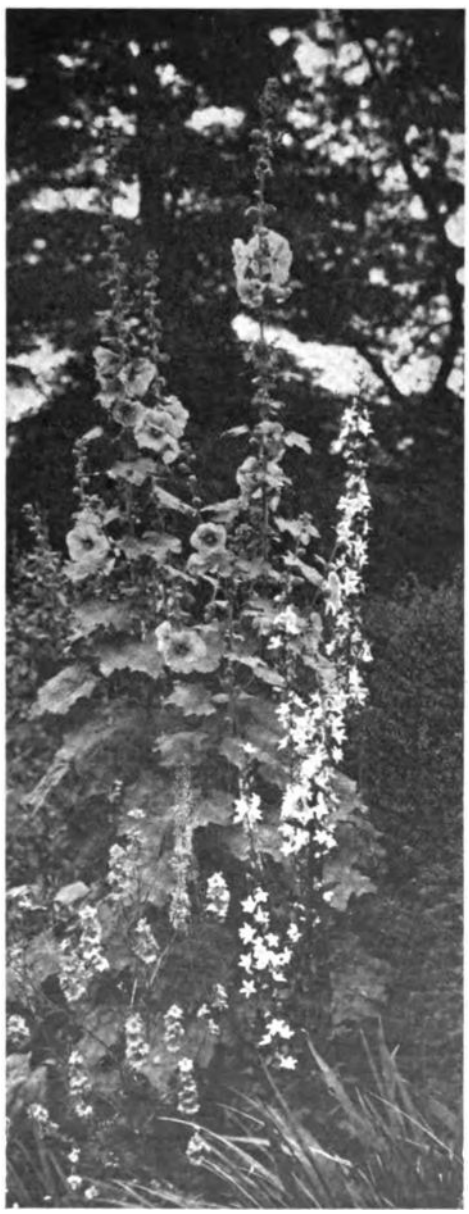
"THE HOLLHOCK DISDAINS THE COMMON SIZE OF HERBS AND LIKE A TREE DO'S PROUDLY RISE."

FLOWERS of an old-world garden, hollyhocks are not as other flowers are; their very attitude is one of aloofness from the common crowd. As they stand erect, unbending, towering above the rest of the garden's population, there is something in their detached and magnificent attitude that is of compelling attractiveness. Place a belt of hollyhocks in a garden within view of passers-by, and the most callous among those who know not gardening will not pass without taking a second glance and, consciously or subconsciously, paying homage to their unique character. Few, indeed, will see a hollyhock in bloom without involuntarily switching their thoughts back to the days of early childhood, and the older the person the more vivid will be the reflection, because it was when the veterans of to-day were children that the hollyhock held sway with regal splendour in British gardens.

Fashion, they say, rules among flowers as among people; but the hollyhock was never the victim of fashion's caprice, its enemy was the abominable disease which at one time well-nigh threatened its extinction, and did in fact wipe out many fine collections. Even the scourge of the hollyhock disease found its footing and worked its havoc not by reason of any neglect arising from waning affection, but rather through the over-zeal of its devotees, who carried skilful culture to a point that weakened the constitution of the plant and rendered it vulnerable to attack from its sinister foe, Puccinia malvacearum, the "hollyhock rust."

The name of Chater will always be as music to the ear of the lover of hollyhocks, because he not only produced some of the best varieties, but evolved and maintained a strain possessed of such stamina and vigour that it survived the grim battle with disease and defied its power to kill. This year is the centenary year of Chater's Hollyhock Nursery at Saffron Walden, and to-day, after a hundred years, the same superb strain, but rejuvenated by the production of modern varieties of robust constitution, grand form and gorgeous colour, may be seen in the same establishment wherein they grew in 1824, and from whence seeds and plants are distributed in ever increasing quantity to all parts of the world. Messrs. James Vert and Sons, the present proprietors of the Saffron Walden Nurseries, are as prominently the leaders of the cult of the hollyhock to-day as was Mr. Chater a century ago. Thanks to the co-operation between practical horticultural skill and pathological science the malignity of the hollyhock disease has been overpowered, and with clean, healthy stock and rational treatment the hollyhock is still capable of holding its proud position among the noblest nhabitants of the British flower garden.

The "rational" treatment presents no great difficulties when the adjective is submitted to clear interpretation, and perhaps the clearer idea of its intended meaning will be gained by first mentioning the departures from rational treatment which caused mischief in the past. The exhibitors of hollyhocks, who belonged to the old school of florists, were rigidly bound by their standard of "points" in the flowers they grew, and when a variety conformed to that exacting standard it was cherished and watched over with doting care. The only means of propagating such varieties was by cuttings, in itself an unnatural method of treatment for such a plant. The young rooted cuttings were of necessity given winter protection under glass, and when in spring the plants were turned out of pots into their flowering quarters they frequently had a considerable quantity of soft young foliage, but a comparatively small, weak root system. The soil into which they were planted was invariably "fat" with rich nourishment, liberal manuring being the great idea of every grower of exhibition plants. Ensuing growth was consequently very soft, sappy and flabby, to use an inelegant but expressive term. There followed still other operations which tended to concentrate upon development of size, but not upon improvement of stamina. All side shoots were removed, leaving the one main stem of the plant to be gorged with an abundance of nourishment, the richness of the soil being supplemented by liquid manures and often by mysterious concoctions which had more of the character of quack tonics than scientific plant foods. Thus was bloated foliage produced, which obviously would fall an easy prey to parasitical or fungoid diseases, and the one particular fungus which makes malvaceous plants its hosts and victims had opportunity thrust upon it to indulge in rampant aggression. The use of fungicides was not so well understood as to-day, and many growers adopted no other means of attacking the disease than denuding their plants of foliage. The fate of the succeeding generation of plants was sealed by propagating from diseased plants, and thus the disease became a veritable scourge.



THESE OLD-TIME FLOWERS LEND DISTINCTION TO THE SIMPLE BORDER.

The system of propagation in vogue during that period was obligatory, because it had not yet been made a matter of careful study to discover means or methods of maintaining seed stocks at a standard of purity which would ensure reproduction of a true variety. To-day we have, thanks to the untiring efforts of our specialists, stocks of seeds which may be relied upon to reach a very high average of true reproduction, and this fact makes rational treatment a possibility. For it needs no argument nor explanation to convince plantsmen that the natural method of reproduction from seeds is calculated to produce and maintain healthier and sturdier stock than can be secured by persistent propagation by cuttings.

Rational treatment consists of open-air culture, sowing seeds in the open in early summer, and transplanting in the autumn. The soil must be thoroughly well prepared by deep digging, attention to drainage and porosity, and manuring; but instead of putting young seedlings into soil which is over-charged with manure, the bed will be sweetened (when necessary) with lime, wood ash or burnt earth, the greater part of strong feeding being postponed until the active growing period between spring and the opening of the first blossoms.

We of the present generation have learned the value of spraying

Digitized by Google

and it is part of rational culture that suitable fungicides shall be used either in the form of a dry powder spray or in liquid form. There is no lack of suitable materials scientifically prepared by qualified horticultural chemists and it is no part of my mission to indicate preferences between the many which are excellent. The great thing is to spray in good time, and to follow in detail the instructions of the manufacturers in regard to mixing and application.

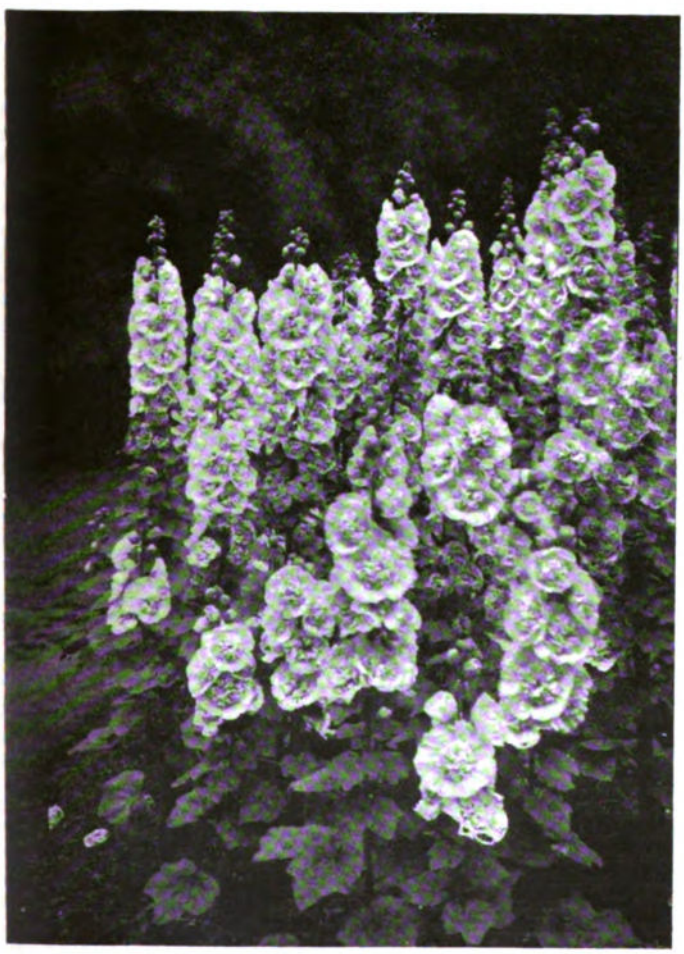
Having dwelt upon the great boon which the availability of true seeds undoubtedly is, I would dissipate any possible inference that propagation by cuttings must be entirely shunned. That would be an unfortunate misapprehension, for in order to fix and perpetuate a particularly fine variety it is quite legitimate to strike cuttings, and the retention of named varieties is essential to the continued popularity of the hollyhock.

We have this consolation, however, that our specialists are not now confined to persistent propagation by cuttings for the maintenance of true stocks, and are therefore ever watchful and alert to discard any plants which show the slightest deterioration in health and stamina.

There is no necessity for me to write of named varieties. Nothing that I could say would convey more information than is already available in specialists' catalogues, and the simple fact that I am particularly partial to Crimson Queen, Alfred Chater, Chastity and a few others is no reason why I should dictate to those of other tastes.

Form as well as colour must of necessity be studied by the exhibitor; but for garden display colour is of paramount importance, and it is purely optional whether that should be sought in named varieties or a good strain of seedlings, or, indeed, whether double-flowered or singles shall be grown. Many people are of opinion that single flowers are superior to doubles, and there are superb single-flowered hollyhocks which are capable of making glorious displays of colour.

The fig-leaved hollyhock (Althæa ficifolia) is a plant of distinctive character, the delightfully cool shade of yellow, elegance of flower, leaf and bushy habit being particularly



PINK HOLLYHOCKS ALWAYS GIVE A PLEASING CONTRAST WHEN SITUATED IN A GREY BORDER.

THE DISTINCTIVE CHARACTER AND ELEGANCE OF BLOOM ARE NOTEWORTHY IN THESE TIME-HONOURED FLOWERS.

noteworthy in a plant of large proportions. Hybrids of this species, retaining the elegance of deeply lobed foliage and bushy habit, but embracing many pleasing shades of colour, are worthy of extensive planting, and they are strikingly effective when grown in clumps with a background of tall coniferæ or trees and shrubs of dense, dark green foliage.

The staking of hollyhocks is a matter calling for something more than casual attention. The most unsatisfactory method of staking is to tie tightly the middle of a tall spike to a stout firm stake, leaving the upper portion to be buffeted about by the wind. Often a rough storm will result in the stem buckling over at the point where the tie encircles it. Tall, thick poles towering up among the flower spikes are unsightly; but an inconspicuous and effective stake is a bamboo cane thin enough at the top to be pliable, but stout enough at the bottom to be firm.

A couple of ties will hold a big stem securely, and when strong winds prevail the cane will bend with the stem, reducing resistance to the wind, and after the pressure is relaxed the cane reverts to an erect position, drawing the stem with it. This method will also ensure that the topmost part of the stem will not be broken off or unduly injured by the wind.

Hollyhocks are probably seen to the best advantage when they are massed together in a circular or oval bed. In such positions they have a most imposing appearance, as will be readily seen at Kew. As a background to a border, perhaps hiding a tall wooden fence, they are also admirable, and they generally do exceedingly well in such places, as the fence affords a certain amount of shelter from the prevailing winds. Their height and variety of colour are valuable assets in a herbaceous border and a plant which could be included when the border is in the making. No matter where these plants may be, however, they always bring joy to the eye of the onlooker and, in addition, they harmonise exceptionally well with any colour scheme that may be attempted.

ON RAISING IRISES FROM SEED

BY W. R. DYKES.

IT is always astonishing to find that comparatively few gardeners take the trouble to raise perennials from seed. It is quite true that in most cases garden varieties will not breed true and that all the seedlings from one pod of seed are usually slightly different from each other; but, on the other hand, there is no better way of obtaining a large number of healthy plants, for home-raised seedlings are often far more vigorous than stock which is raised by the division of purchased plants. Besides, there is always the chance of obtaining some striking new variety.

IRIS SIBIRICA BY THE WATERSIDE. - THE SEEDS OF THIS SPECIES GIVE THE BEST RESULTS WHEN PLACED IN A MIXTURE OF LEAF SOIL AND SAND.

There is no mystery about raising irises from seed, nor is it a very lengthy process. In fact, it is not impossible even now to sow seeds of Iris pumila, which will germinate early in the spring. If the young plants are carefully grown on and planted out as soon as possible, some of them may even flower next autumn, while all should flower in the following spring.

The chief difficulty will probably be to obtain the seeds. Few nursery firms offer iris seeds in their lists; and those lists which do contain them do not usually appear until the New Year. Now, if iris seeds are not sown until the New Year, they will often lie dormant for a year before they germinate. Even if they are sown as soon as they are ripe, some hybrid seeds will lie unchanged in the soil for ten or fifteen years, and then germinate; but, as a general rule, seeds of species and of the common bearded hybrids which are sown in October or November will germinate readily in the spring.

Seeds should, therefore, be obtained in the autumn from a nursery or from a friend's garden and be sown with as little delay as possible.

Very little that is accurate seems to be known as to the conditions under which seeds germinate most readily. My own belief and experience is that germination is much more certain in an open porous soil than in the close, finely sifted soil in which it seems to be the custom for gardeners to sow seeds. Possibly this finely sifted soil may be necessary in cases where the seeds are extremely minute; but, unless the seeds germinate quickly, it is extremely difficult to keep pots of this finely sifted soil free from moss, which, if allowed to remain, must tend to choke the tiny seedlings.

Iris seeds are by no means minute and, if the soil is passed through a ¼in. sieve, it will be quite fine enough. The actual soil which is chosen will depend on the section of the iris genus to which the seeds belong. In all cases the basis may be well rotted leaf-soil. If the seeds are those of bulbous species or of the bearded irises, then leaf-soil and sifted mortar rubble may be mixed together in equal proportions. If, on the other hand, the seeds are those of the Californian species or of I. sibirica and of its relatives, then sand or sandy soil should be substituted for the mortar rubble.

The pots should be carefully drained, and I have for years used circles of wire gauze instead of pieces of broken flower-pots with which to cover the hole at the bottom of the pot. Over the wire gauze is placed a little moss, and I find that this drainage remains good for several years. No worms can get into the pots through the wire gauze, and this is certainly no small advantage, for worms in a seed pot are apt either to throw the seeds out on to the surface of the soil or to drag them down too far beneath it.

When the drainage has been provided, the pots are filled with the prepared soil to within rather less than an inch of the top. There is no need to ram the soil down hard. One push with the fingers and a shake of the pot settles the soil in position, and the seeds may then be sown and covered with about half an inch of the prepared soil. Then the pots are well watered in order to soak the soil thoroughly.

The next step is to plunge the pots to the rim in the open, either in sand or in ashes. In sandy soil they can just be sunk in the ground, but when the soil is clay it is better to make up a special plunging bed of ashes and to put the seed pots into this. It is a great mistake to coddle iris seeds, and they should never be placed in a frame in the autumn. The stagnant air seems to have a bad effect on the seeds, of which a large number rot without germinating; while those which are fully exposed to the action of the weather germinate much more readily. More than once I have amused myself after a fall of snow by rolling huge snowballs across the lawn and then on to my seed pots, until I have been able to pile the snow up four or five feet high. Such a heap usually takes a week or two to melt completely away, and when it is melted a sharp look-out should be kept for the tips of the young seedling leaves.

As soon as the tips of these appear, the pots in which germination has begun should be placed under glass, either in a frame or in a cold-house. The object of this treatment is to take advantage of the slight increase in temperature which is found under glass and which will assist the young plants to grow rapidly.

The object of making them grow rapidly is to ensure that the young plants should be big enough to be planted out in their permanent positions if possible before the end of May and in any case early in June. This applies, of course, only to the rhizomatous species, for if the seeds of the bulbous irises are not sown too thickly, the young bulbs may be left to

Digitized by Google

complete a second season in the pots in which the seeds were sown. As soon as a plant has made four or five leaves, of which the longest are about four or five inches long, it is ready to be planted out in the position where it is to flower. The holes for the plants should, of course, be made with a hand-fork or trowel and never with a dibber; and if the soil is very dry it may be necessary to fill each hole with water before inserting the plant. The surface will then be left loose and dry, thus acting as a mulch and the water used will be available for the roots of the plants and will not be so rapidly drawn out of the earth by the sun as is the case when it is poured on the surface after the plants are in position.

Seedlings of bulbous species should remain in an airy cold frame in their first season until the leaves turn yellow and die down. Then the lights should be left on the frame until September or October, so that the soil in the pots becomes quite dry and warm. In the autumn the old leaves may be cleaned off, taking care not to pull out the young bulbs with them; and a top-dressing of fresh soil of the same composition as that in which the seeds were sown may then be applied with advantage. The frame should now remain open until the young leaves appear and the lights need only be put on to protect them against bad weather. At the end of the second season the bulbs should be lifted out of the pots and planted in their permanent positions early in the autumn. Two years later the first flowers should appear.

All seed pots must be weeded occasionally, and for this purpose the fine sharp point of a knife is as good as anything. With this it is often possible to cut through the root or roots of the weed, which is just pulled up as far as it will come without tearing up the soil or disturbing the seeds or young seedlings.

THE INVALUABLE PYRETHRUM

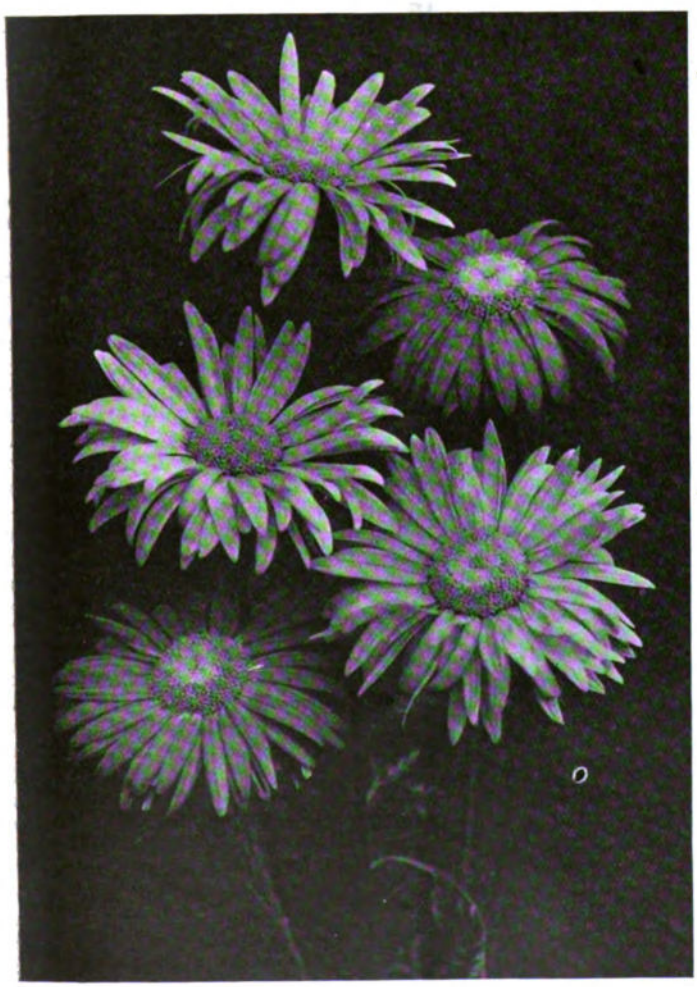
PYRETHRUMS undoubtedly deserve their wide popularity. Their season of flowering alone would ensure this. When, in addition, the wide range of colouring from which one may choose is considered, the fact that they are becoming more and still more a favourite flower is easily understood.

Pyrethrums are not at all particular as to soil, except that they are not fond of a heavy clay. They need a certain amount of moisture if they are to bloom to perfection; the result of an over dry season being registered by small insignificant blooms on very short stems.

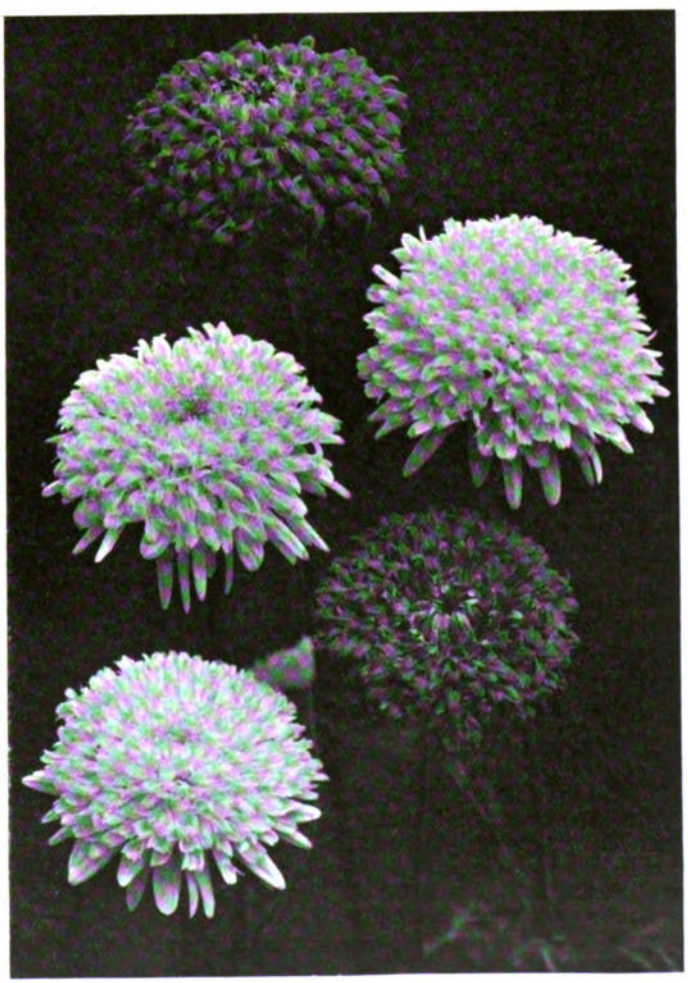
It is not always possible to find them a sheltered position in the garden with a southerly aspect, but this does not matter if they are planted in a reasonably warm situation and one in which they receive a fair share of sun.

Pyrethrums like best of all a soil which approaches a light or medium loam, and preparation for planting consists mainly in deep digging and well manuring the site or sites in which they are to make their home. If farmyard manure, which is expensive, cannot be obtained, Wakeley's Hop Manure will be found to be an excellent substitute. In addition to containing materials which render it valuable as a plant food, it will be found to be more economical. Plenty of space in which to expand should be allowed, as once they become established they grow rapidly, and unless they are divided about every third year they will have a tendency to become unwieldy, besides which the flowers will annually decrease in size.

Although pyrethrums may be grown from seeds, the experience is rather in the nature of the lucky bag of our childhood, one is never quite certain what will be the result when the seedlings



LATE-FLOWERING SINGLE PYRETHRUMS, INCLUDING GENERAL FRENCH, OF A CRIMSON MAROON SHADE.



THE WHITES AND CRIMSONS IN DOUBLE PYRETHRUMS ARE ALWAYS POPULAR.

Digitized by Google

reach maturity. Choice varieties may be better increased by division of the roots every third year, and care should be taken not to divide these into divisions so small that they are of little value for planting. A three year old plant may be comfortably divided into about four or six parts, according to the size it has reached.

From the point of view of beautifying the garden the value of pyrethrums lies not, perhaps, so much in their splendid colouring effects, as in the season during which these effects are at their best. The pyrethrum bears its first and biggest bouquet during the month of May, when there are comparatively few flowers available and when it is certainly queen of the garden.

The planting out season is in autumn or in the spring, and although one authority states that the best time to divide the roots and to replant is immediately after the first flowering, the more generally accepted seasons will be found best to serve the purpose of the gardener.

Among singles there is a magnificent variety of recent introduction, which, as it becomes known, will certainly prove a first favourite for the garden, as well as in the matter of cut blooms for the house. Eileen May Robinson bears exceptionally large flowers, which in colour are difficult to equal for beauty, being a bright rich pink of a more beautiful shade than any of the older varieties of the same colour.

Eileen May is a vigorous plant, and, if fortunate enough to find a home where there is sufficient moisture in the soil, it will send up a glorious head of blooms which will not be matched anywhere else in the garden. Although this variety, which obtained an award of merit at the R.H.S. in 1922, excels all others, there are many very beautiful varieties which cannot be left out of a garden if monotony is to be avoided. Among these may be mentioned one or two of the already well known Kelways. A brilliant crimson scarlet is James, while Agnes Mary is a large-flowered variety of a bright deep rose colour; both of these are singles. Clemence is a single of some merit; but for earliness the Comet, which is a brilliant crimson, is to be preferred. Another early-flowering variety which is also a rich crimson is Mrs. Bateman Brown, the flowers of which are of exceptional size. General French is a late-flowering variety which has a colouring of crimson maroon, and is single, like all mentioned up to the present.

Among double pyrethrums there is, of course, the old favourite Queen Mary, with its bright pink blooms of rather large size. It flowers more freely than do many other varieties, and for this reason is loved by commercial growers. Captain Nares is another old favourite of a bright crimson colour, which colour is not found so frequently among doubles as it is among single varieties. However, there is the Melton for those who like a deep crimson bloom—and who does not? Whites are always popular, and if they are not over common among the singles, there is no lack of them among the doubles. First to bloom and valued on this account alone is Carl Vogt, the flowers of which are exceptionally large. Mont Blanc is perhaps too well known to need description, except perhaps as a reminder that it is freer than most other varieties. La Belle Blonde and La Neige are other pure whites which are worth noticing.

The fact that pyrethrums bloom a second time later in the season is not of such great importance in the garden as there are at this season many other flowers flowering to perfection. On the other hand, pyrethrums never send out a great quantity of bloom at this second effort. It has been suggested by some experts that greater perfection will be obtained the following spring if the autumn buds are cut off before they have time to open.

Careful staking and tying are necessary just before the buds open. If this is neglected and the weather chances to be rough, the flower-stalks will get twisted in all kinds of odd ways, which does not add to the beauty of the plant. Should there come heavy rains when they are in flower, the blooms will be beaten to the ground and present a bedraggled, untidy appearance in the garden.

Pyrethrums belong to the chrysanthemum family, and while in spite of the wide range of colouring they are much limited in this respect than other members of the family to which they belong every year sees the margin extended. It cannot be long before entirely new colours are added to the list, which will further enhance the esteem in which this valuable flower is held, and even to-day few gardeners consider their spring flowers complete unless more than one of the more popular pyrethrums have a place among them.

J. W. MORTON.

HARDY PERENNIALS for SUB-TROPICAL GARDENS

SUB-TROPICAL gardening, with its infinite possibilities, might be made a feature of many gardens but for one obstacle—its expense. One looks round to see where this high cost comes in and it is not at all difficult to locate. The large numbers of tender and half-hardy plants that are employed need considerable heat to raise them and house them during the winter and spring months. Both fire and labour are costly, and the whole matter does not seem worth while.

Yet one longs for the splendid "foreign looking" pictures and the noble and luxuriant effects, and one considers once again if it is not a practical possibility, without an over-draft upon the garden account. It is. Those two words are a very definite statement; and in two words more we can give the answer: Hardy perennials.

The right kinds of hardy perennial plants, well chosen and well placed, provide a "backbone" of noble and luxuriant flower and foliage among which but a very restricted number of really tender plants are necessary. These, of course, should be placed just at the most prominent points, where they will tell to the fullest advantage and thus the sub-tropical garden may be run at no higher cost than ordinary summer bedding. Closer examination of the matter will reveal an extremely wide range of plants that may be used, all of them of the utmost hardiness and capable of standing in the open, unprotected for many years without any more care than that which is usually bestowed on border flowers. Where hardy plants are used as the "backbone" for a piece of sub-tropical gardening, it is better to keep those kinds out of the general garden and not to allow them to appear in both places, otherwise the effect produced in one direction is apt to be marred by their appearance in another.

One of the first plants that will occur to the mind of the intending planter is the acanthus—a plant that looks best when used singly. This gives an opportunity for the magnificent leaves to spread to their fullest extent, without

DIFLORA, ONE OF THE DAY LILIES FROM THE EAST.

Digitized by Google

competition with their fellows, and thus the noblest appearance is obtained. Let us not forget, in our praise of the splendid shining leaves, the curious and substantial heads of flower that are such a feature of the plant in August and September and that add not a little to its tropical appearance.

Beautiful effects are provided by a rather common plant, Iris fœtidissima fol. var., in which the leaves are strikingly variegated with green, gold and silvery white. Do not give rich soil to this, for the poorer the soil the more marked the variegation will appear. Where space is ample and plantings can be on the grand scale, nothing excels the pampas grass—Gynerium argenteum—which is useful throughout the season. Place this where one can get all round it and it is thrown out perfectly clearly and distinctly and none of its wonderful grace is lost by too close contact with other foliage. The huge plumes of feathery white grass do not appear until late, but, in combination with the gorgeous red-hot pokers, create an effect that is entirely their own.

In addition to the association of the red-hot pokers with the pampas grass, the use of the Kniphofias alone and on a lavish scale should not be omitted, for, with their luxuriant arching grassy foliage and vividly brilliant flower spikes, they are among the very best of all hardy plants for our present purpose. Many of the best varieties attain the zenith of their flower perfection in August and September, just when the sub-tropical plantings are at their most luxuriant stage; but, even in the early summer days, by including some clumps of such varieties as Tuckii with its yucca-like leaves and gold and scarlet spikes at a height of 4ft., noble effects are easily possible, and one wants the sub-tropical garden to be interesting over as long a period of the year as possible.

For surrounding and backing up, especially from the point of view of wind shelter, the bamboos are magnificent—and in the phrase "wind shelter" there is quite a valuable point. Although the bamboos themselves do not like to be too violently swayed, there is a very subtle attraction in the musical rustle of the leaves and stems as they gently stir in the wafting breeze, and the most should be made of this when planning out the garden. Happily, the family is a very large one, and bamboos are available ranging in height from a few inches to 16ft. or 20ft., so that, whatever the scale upon which the proposed planting is being made, it will be easy to choose suitable varieties for the purpose. Where the plantings are on a large scale and truly immense plants can be included, the gigantic leaves of the gunneras should be employed for every ounce they are worth. By the waterside especially they attain dimensions that can only be described as gargantuan, and when associated with Heracleum giganteum or H. mantegazzianum, extraordinarily bold pictures are produced.

Placed where it may run freely—as it quickly does—the plume poppy, Bocconia cordata, is really lovely and the larger the masses that can be accommodated the finer the effect. Although the plant is naturally a tall grower, it should be set, wherever possible, on a raised mound, for this still farther raises the plants and thus exposes the silvery stems and beautiful underside of the foliage. The wonderful plumes of feathery flower and charmingly cut leaves add not a little to the whole, and the plant remains decorative until very late in autumn. Thistles, both annual, perennial and biennial, are very valuable and, in this connection, special praise may be accorded to Carduus eriophorus. This rises to a stature of 4ft. and, with its handsome leafage and beautiful purple flowers, forms a most imposing specimen. Phytolacca virginica, the red-ink plant, is characterised by strong erect bushy growths that attain a height of 5ft. and are noticeable in autumn for their long spikes of purple berries which, when crushed, exude a red fluid, hence the name red-ink plant.

Sharing the love of moisture characteristic of the gunnera, the fuller teasel, Dipsacus Fullonum, gives splendid effects. It is well to remember that this is only a biennial, and one must renew the plants by seed annually, otherwise a big gap will be left where the former plants have died. The greenish-white flowers, at a height of 4ft., are extremely decorative for many weeks; indeed, the plant is ornamental from June to late September.

The larger-leaved funkias, used in great masses, are simply grand, although one always regrets that the magnificent variegation which is so prominent a feature in early summer is not retained in its fullest beauty throughout the season. For our present purpose, F. Fortunei robusta in which the leaves are shining green and each reaches a length of about 2½ft.; tardiflora, with its splendid form, shortly stalked leaves and its handsome flowers in full beauty in late autumn; and Sieboldi glauca, with strong glaucous green leaves and purplish flowers from July to September, are all especially good. All of these may be employed as a ground-work for tall "dot" plants of vigorous growth and, wh present a magnificent effe

BONE FERTILISERS

I SHOULD like to call attention to the use and value of bones in the garden, especially as the time for application of most bone fertilisers is now at hand. There are quite a number of products on the market which consist of bones in some form or other, but in many instances little use is found by the horticulturist for them, and valuable mild-acting fertilisers are thus missed.

Bones themselves in their raw state are totally unsuitable for application to the ground, although this is sometimes advised. If one buries a hundredweight of bones after carefully saving them up for a few weeks with the assistance of the cook, or after purchasing them in a sack from the nearest slaughterhouse, one finds on digging them up again that there is very little change in their form. In other words, the plant food contained in the bones has not been dissolved to any appreciable extent, and hence one's crops have not been able to benefit by the application. Some kind of treatment is, therefore, essential if the locked up plant food in bones is to be of use, *i.e.*, grinding, charring, dissolving or intermixing with other materials.

In a short article it is impossible, of course, to do justice to each one of the very numerous bone fertilisers which can be obtained. I have selected, however, some which I consider to be the most important, and brief comments on these are now appended.

Animal Charcoal.—This product is identical with bone black or bone char, both of which are used by sugar refiners. As is mentioned under bone black, the form known as spent char is generally applied as a fertiliser, and often proves valuable as well as being quite inexpensive.

Bone Ash.—This material is the result of burning bones. Chemically it consists very largely of insoluble phosphate of lime, and has practically no organic matter or available nitrogen. Bone ash has, therefore, to be regarded as a very slow-acting phosphatic fertiliser, suitable only for autumn application and best applied when preparing flower or fruit borders which will stand undisturbed for a considerable period. It should be applied to these in the form of a fairly heavy dressing, *viz.*, 4 oz. to 6 oz. per square yard, and well mixed in with the soil. As it is a comparatively inert fertiliser, it is perfectly safe to mix it with dung or with other artificials.

I should like to point out one unrecognised use of this material, namely, as a dressing to manure-sick soils which are inclined to become permanently sour. These soils when tested prove acid in character, and although the acids are of a weak character, they are quite able to attack this insoluble phosphate and render it available for plant life. Soils treated with bone ash immediately show a reduction of sourness, and the crops grown upon them mature earlier, due to the action of the soluble phosphate which has been produced.

Bone Black.—As already remarked above, this is also known as bone char. In a fresh state it is rarely used as a fertiliser, but in the neighbourhood of sugar refineries, refuse or junk known as "spent char" may well be pressed into service. This consists largely of insoluble phosphate of lime with a fair proportion of finely divided carbonaceous matter. If not offered in a fine powder it should be thoroughly ground, as otherwise it will only dissolve very slowly in the soil. Despite the fact that this is used as a purifying agent, it very rarely contains anything of a poisonous character as far as plants are concerned. There is a chance, however, of it coming into contact with undesirable barium compounds, which are also used in sugar refining, and in the case of an application giving a check to growth or otherwise proving undesirable it is well to have the sample tested, which can now very easily be done by application to one of the many reliable agricultural chemists.

Spent char should be used as an autumn dressing, and can safely be applied to the ground at the rate of about 3 oz. to the square yard.

Bone Dust and Bone Flour are very similar in appearance and in composition, although one brand described as bone dust contains a considerable proportion of organic matter with nitrogen available as ammonia. Personally, I think it would be better if these two materials were not sold as each other. Bone dust should be the form containing phosphates and nitrogen with a reasonable amount of organic matter, but finer in character than bone meal, which I shall describe immediately; while bone flour should only be sold as steamed bone flour, *i.e.*, a material from which all organic matter and nitrogen has been removed in the production of glue, gelatine and similar materials. In either case, however, the materials will be found to be slow-acting fertilisers of a perfectly safe character, and may be applied to the ground at the rate of from 4 oz. to 6 oz. per square yard any time before the end of December. These two materials will be found exceedingly useful in the preparation of fruit borders both inside and out. They can also be used as mild stimulants when getting ready rose borders and so on, the phosphates they contain becoming slowly available, and the effect of both being of a lasting character.

Bone Guanos.—Mention must be made of these, although it is undesirable that materials should be marketed under this name. Bone guanos are of very valuable composition, and may contain large or small quantities of both soluble and insoluble phosphates, as well as some soluble nitrogen generally in the form of added sulphate of ammonia. Up to now they have proved full of impurities, and one frequently hears of samples which have been submitted for analysis containing very substantial amounts of sand, chalk, road dust and other useless components which can be had for the asking. I never advise their use in the garden, as in most instances the gardener is paying for rubbish.

Bone Meal.—This is a very valuable material for use at the present time. The genuine article consists of untreated bones which have been submitted to comparatively fine grinding, but are not in such a fine state of division as is a material described as bone dust. Bone meal should thus contain a substantial amount of organic matter and nitrogen which, of course, is generally reckoned as ammonia. Analysis will, in addition, reveal the presence of a fair amount of fat which, although often considered to be undesirable, makes the meal more lasting in its effects as it does not dissolve in the soil except very slowly. The major portion of bone meal is, as goes without saying, phosphate of lime, and in order to prevent the material fermenting it is customary to add salt to it, and this must not be considered as an undesirable adulterant.

For use outside bone meal is generally applied at the rate of 4 oz. to 8 oz. per square yard. It can be used with or without dung, and being of a harmless character most other fertilisers can safely be mixed with it. It is valuable as a dressing for lawns, can be applied as a top-dressing to herbaceous and rose borders, while it should be freely used as an addition to potting soil for grosser feeding subjects, such as chrysanthemums, tomatoes and so forth. A large potful to a small barrowful of soil will not be too much, while for both outdoor and indoor vine borders, and peach borders it will prove exceedingly useful. For indoor work generally a smaller quantity is used, say 3 oz. to 4 oz. per square yard, and this is well pricked into the soil before mulching with manure.

Bone Superphosphate. — This and *Dissolved Bones* should be the same thing under two different names. That usually sold as bone superphosphate is generally a rather coarse superphosphate with bits of bone plainly visible in it. Dissolved bones, although obtainable in several grades, do not, as a rule, indicate their source of origin quite so plainly.

I should like to mention that dissolved bones can be prepared at home without much difficulty if the gardener, assisted by the cook, saves up all the bones from the house. About 5cwt. of bones is a convenient lot to work on, and for this amount round about 2cwt. of strong sulphuric acid will be required. After making the bones into a large pile and thoroughly moistening them with soft water, a thick ring of fine ashes should be put round. One must then put on a strong pair of goggles and a leather apron, as well as a coarse pair of thick gloves, and then pour the acid cautiously over the pile. Great heat is sometimes produced during the addition of the acid, which, by the way, is exceedingly corrosive, and no effort must be spared to prevent this from getting on one's flesh or clothes. After the addition of the acid, cover up the pile for a few days with slates, stones, etc., then remove the ring of

Digitized by Google

ashes, breaking the dissolved material up with a pickaxe if necessary, and submit it to grinding in an improvised pestle and mortar prior to bagging up for use next spring or during the summer months. The rate of application is from 1 oz. to 2 oz. per square yard.

Floated Bones.—These are a dust-like American product which is rarely offered in the English market. The action is similar to bone meal or bone dust, and the rate of application is similar also.

Half-inch and Quarter-inch Bones.—Although years ago it was customary to dig these into the ground when preparing it for fruit, roses, shrubs, climbers, etc., nowadays they are almost entirely reserved for use in potting materials. On account of their size they are very slow in action, and it is doubtful to my mind whether the application of them is strictly economical at all. A large potful, or in some cases a couple of potfuls is added to each barrow of soil, and thoroughly mixed in with it. The names, of course, refer to the size of sieve through which the coarsely crushed bones are put to prepare them. The finer material after such preparation is then ground in the form of meal while the coarser pieces of bone are again crushed to prepare more of the half-inch and quarter-inch variety.

Some gardeners use half-inch bones as drainage material in the bottom of pots or boxes. This is not at all desirable, as the bones are apt to ferment in contact with excessive moisture and may block up the drainage holes entirely.

Putrified Bones.—These are really semi-soluble bones prepared in various different fermenting or putrifying processes. A common one is to fill a barrel with bones well mixed with wood ashes, and to teem strong house slops into it at regular and frequent intervals. The bones fall to a coarse powder, a fair proportion of which is soluble in water, and on the whole the material resembles low-grade superphosphate in character and can be used in the spring in a similar way.

Vitriolated Bones.—The last bone fertiliser which I will refer to in the present notes is that sometimes described in the market as vitriolated bones. As its name suggests, it is the product of the action of sulphuric acid or oil of vitriol on bones. In composition it is almost identical with bone superphosphate, although it is sometimes equalised by the addition of sulphate of ammonia to increase its content of soluble nitrogen.

This in common with all other soluble fertilisers from bones should only be used during the growing season.

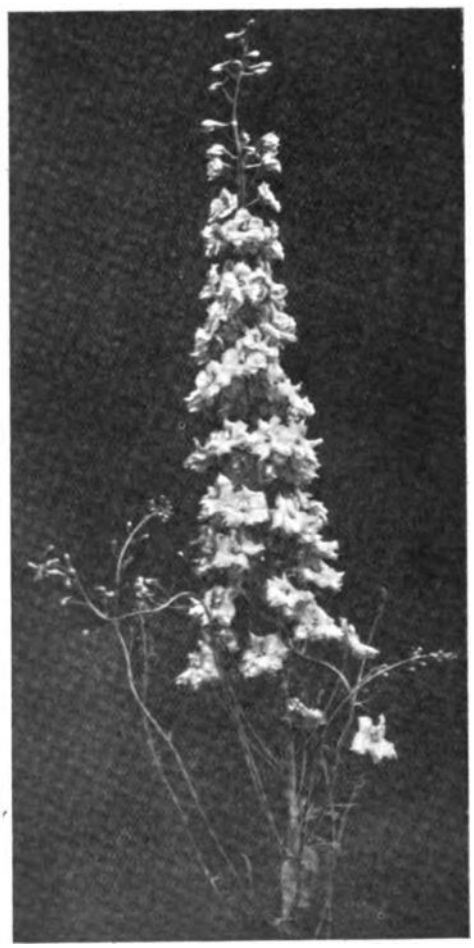
E. T. ELLIS.

THE WREXHAM DELPHINIUMS

A LONG SPIRE-SHAPED BREED OF DELPHINIUM, DIFFERENT IN APPEARANCE FROM THE USUAL BLUNT-ENDED VARIETIES.

I THINK the first time I was aware that there was such a person as my good friend Mr. Watkin Samuel was some time in the summer of 1920, when I received a few blooms of a tight little double-flowered delphinium from Wrexham with a request for my opinion about them, and at the same time the hope was expressed that another year I would manage to get over and see the plants. The result of this visit I placed before readers of THE GARDEN in the issue of September 3rd, 1921. I told then that his phenomenal successes at Vincent Square and Holland House were the visible results of his ploughing a lonely furrow for twelve long years in his small hillside garden as you approach Wrexham from the east, not, of course, from the west, as I absent-mindedly wrote in that article.

I recalled the pleasure which comes to those who try to unearth the buried treasures which lie hidden beneath so many simple and quiet-looking flowers. Four years more have now been added to Samuel's original twelve, but they have been years of encouragement. His fame has gone out into all lands. Articles of appreciation have been written in papers; dealers' catalogues like those of Bees of Liverpool and Hewitts of Birmingham sing the praises of his productions in England; the list of a delphinium specialist like O. M. Pudor of Pwyallup, Washington, U.S.A., proudly announces on its cover "also describing Watkin Samuel's Wrexham Strain," and letters with something much heavier than appreciation in them reach him in increasing numbers.



A TYPICAL VARIETY, MONARCH OF WALES.

He set out to see if a long spire-shaped spike was not a possibility—one with large semi-double flowers of pleasing colours loosely arranged all round it, and with an attenuated top, such as we get in Advancement and Monarch of Wales. He has accomplished much in this direction, and what he has done is all to the good, for the blunt-ended, bitten off looking spike seems heavy and wanting when compared with one with a tapering end. Now he is more or less concentrating on the improvement of the individual blooms. He wants them to have a well filled up look, such as we find in Forget-me-not, a new seedling. Mauve Glory is a second 1924 seedling. It is a light mauve self with a honey yellow edge to the inner petals on the eye. Forget-me-not is a light mauve with a centre of forget-me-not blue (Ridgway's Chart) and a light "bee" or eye. It is an exceptionally flat flower. These are samples of the very latest out. They seem to indicate that he has struck a good vein of ore. Watkin's slogan is "round pips" (flowers he means, he has borrowed an auricula term) "upon a perfect spire-shaped stem." He has in the above the round, well filled up flower all right, and there is a certain amount of "bee" remaining. I hope this distinctive feature will never be totally eliminated. There is a tendency in that direction. There are seedling raisers, I believe in America, who have this object in view, because no doubt they consider the eyeless flower the more beautiful. Is that so? Am I wrong in wishing to keep as one of the chief factors in an ideal specimen the old original "bee" with which all the earliest hybrids seem to have been blessed? Perhaps some delphinium lovers will tell us what their opinions on this knotty question are. Probably the verdict will be "room for both."

In my notes on my visit to Wrexham this year I say of several flowers, "Eyeless varieties: do not care for these. They look as if wanting something." The life-long association of the "bee" as part and parcel of a delphinium bloom persists with me, but a younger generation will not mind perhaps if it is deciduous and is dropped. Naturally, Mr. Samuel observes the behaviour of seed parents closely. He leaves the actual crossing and hybridising to the bees and flies, and beyond planting selected varieties in close juxtaposition, does nothing

Digitized by Google

but gather the seed. It is the horticultural equivalent of pressing the button, as they do the rest. Among those which my friend puts in the front rank are (1) John Jones, which I rather regret to find Bees have renamed Sealandia, doubtless with the best intention in the world, as their nursery is at Sealand by Chester. Their catalogue says, "If flowers be judged by the same standards as feminine beauty, it is to this exquisite representative of the larkspur family that the prize should go." It has "parma violet flowers tinted sky blue with a small dark eye." (2) Climax, a deep blue and purple variety which has given varieties as different as the mauve Queen Mauve and the true blue St. George. (3) Merry Widow, which I think has gone to Hewitts. (4) Dare Devil, a dark mixture of deep red-violet and gentian blue, in many ways reminding one of the famous Jenny Jones. (5) The Villain, a tall extra dark fellow whose group of tall descendants with their 3ft. 9in. flower-spikes impressed me very much when I saw them in 1923.

The strength of a chain is to be found in its weakest link. So, too, the true test of a strain is to be found in the sort of seedlings it produces in the rough and tumble of the world when it has left the place of its nativity and has been sown in a distant land where expectant eyes are eagerly watching to see its results weighed in the balance. I have only seen them in the "land of their fathers," and perhaps I may be a too rosy-eyed judge as a fellow-dweller in Wales to give an absolutely impartial verdict. It is different when the plants are reared thousands of miles away, when a stiff price has been paid for the seed, and *when they are up against a strain of the grower's* of which he is not half-proud. Yet my friend Samuel has received the following testimony from such a source in a private letter which I have been permitted to see and from which I have copied the following extract: "You have created a delphinium strain of which you have reason to be very proud, and I am proud to display them in my garden and sell their seeds, and the plants later on as the Wrexham strain; *they are in a class by themselves.*" The italics are mine. But isn't it fine to get such a pat on the back? Can we wonder that W. S. thereupon ran out into his garden, planted himself in front of a big patch of one of his special favourites and had his photograph taken! An Irish chieftain wrote to me two or three years ago when matters were decidedly lively all round him, "I have taken to planting strawberries. It is better than taking to drink." I never grasped the why and wherefore for this particular comparison, but I appreciate its good sense. Let me assure my Welsh friend that he too acted wisely and well, for a good many people will like to get an idea of the man and the plants which have made Wrexham delphiniums something very like the eighth wonder of Wales.

The Bishop is "great," but The Archbishop is greater still. It has a wonderful eye, a splendid spike and fine large deep blue petals with a purple edge. Masterpiece and Blue Darling have what Mr. Samuel calls "crawling eyes." No; I cannot say I care for the type. Too much all-over-the-place for me. Tall Boy is one of the never-too-many real blues. Their black eyes set off the individual blooms. As I took note of the long flower-spike of the on-the-short-side Purple Dwarf I wondered if the delphinium would follow the example of the dahlia and present us one fine morning with a dwarf of perennial habit in the style as it were of Coltness Gem. Who knows? I have tried to visualise them. I do not think they would be nice. If we want dwarfs, let us rest contented with the pretty, graceful little annuals that a kind providence with a little human help has provided us with: Blue Butterfly and the rest.

I have one more to mention, Zebra. It is not anything very out of the way except in its "bee" part. The eye is white, but every one of its divisions has a very distinct streak of blue running down its centre quite as well marked, and quite in the style of the little spring-flowering Puschkinia libanotica. Only another straw, of course, but it whispers "potentialities."

A practical word in conclusion. Slugs are death on the nice succulent young shoots of delphiniums. They might be asparagus, to give a simile that most understand. Therefore some time in autumn put a covering of sharp cinders over every delphinium plant in your garden, adding thereto some soot. As to planting, when the soil is stiff it is best to plant in good time in the spring, but it must then be remembered that should there come a dry time fairly copious and constant watering will be necessary. When the soil is light autumn planting is all right. In either case remember the slugs! And remember, too, to stake betimes. When I used to grow a considerable number there always seemed to come a delphinium wind not long before their flowering time, which on more than one occasion caught us napping. It is bad for them, I can tell you, when it does. Remember this wind as well as the slugs.

JOSEPH JACOB.

CORRESPONDENCE

ROSE SOCRATES.

SIR,—On page 380 of Vol. 84 is a note by Mr. E. H. Woodall concerning this rose. He asks, "Does anybody in England possess this sweet rose, I wonder?" I have three or four plants of it if Mr. Woodall would communicate with me.—EDWARD SHOOSMITH, *Packhams, Halland, Sussex.*

BORDER CARNATIONS FOR AUTUMN PLANTING.

SIR,—Mr. Norman Lambert has been writing on the above subject in your issues of the 1st and 8th inst., and although I am in harmony with most things he says in his prefacing remarks on page 745, I draw attention to another important feature concerning autumn planting, probably more so than soil cultivation, etc. As regards his remarks concerning varieties for outdoor growing, he can hardly be blamed for leaving out much; on the contrary, I consider he at times goes too far!

His advice to apply lime in some form or other to soils deficient in that respect is sound; but although he rightly points out the advantages of autumn planting, he hardly goes far enough, because there is probably only one month in which that work is advisable, namely, September. He refers to Mr. M. Allwood's opinion concerning the importance of lime; but after many years' experience, I consider that moderately early planting is more important. If layering, therefore, cannot be done during July or early August and the resultant plants rooted and ready for transference to open quarters by the first week in October, it is advisable to have them put in pots for winter and planted in spring. I have more than one reason for saying that—our recent weather has been a noticeable instance.

I emphasise that point: it is probably the main reason (the secret) why so many fail with carnations planted outdoors. It is also a fact that September planting is more easily done than in October or November. That autumn is better than spring planting is correct; it applies to practically all parts, north or south, where the plants will thrive. There are some places, though not many, where it is hardly advisable to try to grow them in the open border.

On page 746, Mr. Lambert describes ten varieties raised by Mr. F. Payne, but as I have no knowledge of the varieties in question, the less I say the better. But one feature which he mentions—namely, that Glitter and Purple Emperor when disbudded attain the dimensions of 4½ins. to 5ins.—makes me retort that such cannot be ideal varieties even for pot culture! Such statements as "Bursts rather badly" and "Sometimes bursts" are not to be tolerated concerning varieties for outdoor culture.

In his second list Mr. Lambert is on firmer ground because, I conclude, he is speaking from experience. But I have the strongest objection to Bookham Salmon as an outdoor variety after trying it for two years. He says "It has a strong constitution"; my experience is the opposite. Also, Margaret Keep's *form* is by no means *perfect*, and I question The Grey Douglas both as regards form and real hardiness. And may I merely add that I do not consider any yellow self in commerce an ideal outdoor plant? Few possess sufficient constitution; in some parts they do fairly well, but in many they are failures. The old variety Miss Audrey Campbell—if it can be obtained—is, perhaps, still the best as regards hardiness.—R. MORTON, *Woodside Park.*

LILIUM AURATUM.

SIR,—I was much interested in the photograph in your issue of November 1st of a Lilium auratum bearing twenty-seven flowers on the one stem.

I remember some years ago sending you a photograph, which you published in THE GARDEN of October 9th, 1915, page 402, of a Lilium auratum which I had grown bearing seventy-six flowers on one stem. I thought this was rather a record, but the following week one of your correspondents wrote from Scotland that he had one with over 100 blooms on the single stem!

It would be interesting to know what is the record.—W. HUTCHINSON, *Chester.*

SIMPLE GARDENING

WINTERING FRUIT TREES IN POTS.

MANY owners of small glass structures, heated and unheated, like to grow a few fruit trees in pots, such as apples, pears, plums, peaches, nectarines and cherries; lately, I know that some growers are including raspberries. The latter fruit I would leave out of the list, as the plants are troublesome as regards red spider. Fruit trees, whether in pots or open borders, require a rest period, and those permanently in glass structures must have the same treatment as nearly as it is possible to give it, namely, open ventilators and no artificial heat. Now, the trees in pots can be dealt with very easily; frost will not damage the branches nor the buds on them, but it will cripple the roots in the pots if they are frozen while in a wet state and then exposed to the sun's rays. Obviously, then, we should pay attention to the roots. The pots should be placed on a firm bed of ashes, and dry ashes, leaves or short litter packed around them and over the rims, burying the latter quite 4ins. deep. The ideal way is to use ashes and then short litter on the top, the litter being about 9ins. deep. So treated the trees will winter safely. Watering is unnecessary.

SWEET PEAS.

If the seeds sown by readers of THE GARDEN have germinated as well as mine, there will be no occasion to grumble. The young plants are now growing 2ins. apart in large pots; they are 3ins. high, developing leaves freely. All such plants should be shifted to small pots as soon as possible, placing one plant in each pot. The compost should consist of fibrous loam two-thirds, leaf-soil one-third. To a bushel of these combined parts add a 3in. potful of bonemeal and a 6in. one of wood-ashes. Coarse sand may be used, but some old mortar rubble would be better. Place one crock in each 3in. pot, then a small quantity of the fibrous loam. Turn out a potful of plants at a time so that all the roots can be disentangled without unduly breaking them. Allow the long roots of each separated plant to lie neatly round the sides of the pot, filling up with the prepared compost gradually so that the roots are well surrounded by the soil. Do not press down the soil very firmly, apply water, and then place the plants in a cold frame or on a high shelf in a cold greenhouse. During the depth of winter, even, grow the plants hardily, but prevent frost actually reaching them. Although it will not kill them, it certainly cripples young plants grown under glass. Admit air freely night and day except when frost prevails.

WINTER PRUNING OF FRUIT TREES.

I am now referring to hardy fruit trees. Before any cutting back is done the cultivator should take careful stock,

as it were, of the tree. He must cut out, first, all superfluous shoots, such as those on big branches and the tree stems as shown at *a*, *a*. Then, in dealing with the buds, he must note which are wood and which are fruit buds. The former are shown at *b*, and are found, mostly, on young spurs. Older spurs should be dealt with as shown at *c* and *d*, *d*. The cross lines show where branches should be cut. The next branch bears buds at *e*, *e*., two years old and at *f*,*f* and *g*, one year old. The letter *g* denotes the leader. At *h* a wood bud is shown, and at *i* a fruit bud. In some cases both buds must be retained where space must be filled. Young, fan-shaped trees should be pruned as shown at *j*, *j*, *j*, *j*, leaving the centre, *k*, open; this part always fills up with young wood soon enough. The tree bearing one year's growth from the grafting should be cut off at *l*. A bush, pyramid or fan-shaped specimen can be trained in future years.

PEACHES AND NECTARINES UNDER GLASS.

To many cultivators the trees are interesting all the year round, to others they only excite an interest when in flower and again when the fruits are ripening. We should always remember that the trees grown under glass depend upon our efforts to supply them with the very necessary water at the roots. Trees growing outside all the year round are saturated at the roots with rainwater during the autumn and winter. Mere surface sprinklings are not enough, the soil must be thoroughly soaked, preferably with rainwater, several times during the winter months. A very dry soil causes many buds to drop in the spring, directly the sap begins to rise freely. If the subsoil is well saturated, it remains in a moist state for several weeks. Then we must remember, too, that the trees are deciduous and require complete rest in winter. This they have when grown in the open air. Under glass they are warmer even when the doors and all the ventilators are left open night and day, and this should be the rule as far as convenient.

WINTERING BEDDING-OUT PLANTS.

In some gardens it is necessary to find room for hundreds, probably thousands, of summer bedding-out plants. In others only a few of these stock plants are retained. Where there is ample convenience — heated structures — very little difficulty need be experienced. But in gardens where there is not much room under glass and the artificial heat is very limited there is a difficulty. It is wiser in such cases to buy tender kinds of plants in spring from nurserymen advertising in this journal than make the attempt to keep the plants in a healthy condition. Generally, cultivators should guard all plants from excessive damp, especially zonal pelargoniums and others of a succulent nature. Every week it is advisable to examine all the plants and remove faded leaves, to apply any necessary water early in the day so that spilled water may dry up before the night comes. To under rather than over water makes for success, too.

GEORGE GARNER.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London

NOTES FROM CONTRIBUTORS

THE VIRTUES OF TWO TROUBLESOME WEEDS.

AS a nation, we Britishers are profoundly ignorant of the wonderful properties, chemical, medicinal, poisonous and refreshing, which all plants possess, even those which we disdainfully class as weeds. French people, on the contrary, have a use for everything that grows, including couch grass and minor convolvulus, O! British gardeners! Unbelievable but undisputable fact! Think of the couch grass which is burned in rubbish heaps or piled up in heaps to dry in the sun in the summer when it deigns to shine. Such a sight is never seen in France, since roots of couch grass (French *chiendent*) are worth fifteen to twenty francs the kilo! The medicinal properties of this gramineal are soothing, laxative and refreshing. An infusion of its roots makes one of the many *tisanes* which are so much used in France.

In every household and hospital in France *tisane de chiendent* is in constant use as a cure for chest complaints and feverishness and to allay inflammations.

Even in England this despised weed is known to be good for horses, to whom it is often given as a substitute for oats. It makes the animals' coats smooth and glossy.

Agriculturists know, too, that if mixed with quicklime it forms an excellent manure.

Minor convolvulus or bindweed is undoubtedly one of the greatest of garden scourges. From its roots a medicine of great efficacy in intestinal maladies is obtained. Its stolons, like those of the couch grass, are rich in sugar and so form a nourishing tonic.

A good laxative is made by steeping twelve to fifteen crushed bindweed leaves in a half-pint of water. The dried leaves mixed with honey form a good medicine for children which they like taking.—VICTORIA SLADE, *Christchurch, Hants.*

MICHAELMAS DAISIES.

I HAVE a fine collection of these lovely flowers in my garden. They are making a bright display in spite of the inclement weather. As gardeners are keenly interested in Michaelmas daisies, I thought readers of THE GARDEN might be pleased to hear of the varieties which I have found successful. My garden is situated in the suburbs of the city of Cardiff. Beauty of Ronsdorf is a dwarf kind, reaching not more than 3ft. in height. The individual flowers measure 2ins. across on the average. They are a beautiful clear lilac pink in colour and develop with the utmost freedom. This character, combined with dwarfness of habit, makes the variety ideal for small gardens. Climax is now one mass of pale lavender flowers. Some years ago the variety received an award of merit from the Royal Horticultural Society. It is worthy of that honour. The flowers are thrown in rich profusion at the apex of 5ft. stems. The variety named Charmer is endowed with numerous attributes of beauty. The flowers are pink in colour, and they are produced in graceful sprays. The disc or centre is very distinct. I can think of no Michaelmas daisy which is better than this one as a table flower. As a garden flower it takes high rank, being dependable and comely in habit. The variety is 5ft. in height. The blooms of Mrs. J. F. Rayner are a vivid crimson hue, a really attractive sort. When the sun consents to shine the colour glows like fire. The variety makes very strong shoots, which grow 5ft. tall They require no staking whatever in a sheltered situation. I have to speak a good word for White Queen. The white flowers of this variety resemble a snowdrift in the garden. I intend to increase the stock the height of 3ft. being very convenient I grow two deep blue kinds—Eileen and Mala. It is a pity that the best qualities of both varieties cannot be combined in one Perhaps they are. If so, I should welcome information. The flowers of Eileen are a deep and lovely blue; but they are borne in compact spikes of very stiff appearance The flowers of Mala, on the other hand lack that decisive pigment which is essential in a blue flower. The refined, graceful bearing is most attractive. The flowers of Eileen and the habit of Mala would indeed be a charming combination. Both varieties attain a height of 5ft.—GEO. F. COPLEY.

ASTER AMELLUS KING GEORGE.

THE varietal forms of Aster Amellus are numerous, and, as a whole, they are charming autumn-flowering subjects either for border, beds or cutting purposes, especially the variety King George. It received an award of merit from the Royal Horticultural Society on September 8th, 1914, when shown by Mr. Amos Perry, and, seeing that it possesses such a fine constitution, I was much surprised to see it so little in evidence at the recent Cardiff and County Show. It is a plant that should be in every garden, and a dozen specimens would not be too many. This delightful plant attains a height of 20ins. to 24ins., the stems are near and branched, while the flowers are from 2½ins. to 3ins. across. The colour is bright purple blue or bluish violet, with a golden disc, but when the blooms are old this turns to a bright mahogany tint. This plant pays for good cultivation, but any fair garden soil will produce excellent results.—T. W. W.

DOWNER'S Usually Silent LUPINS

are making a great "noise" in the world! "Reports" of wonderful Lupin effects are heard from as far off as America, New Zealand, S. Africa, etc. Large Plants, rich harmonious colours, mixed, 18/- doz. Apply for List.

The Lupin plants (a curious thing),
Like Jack and the Bean Stalk wonders bring,
They almost blossom while you wait,
Throwing up blooms in royal state.

FRUIT-GROWING

OUR contemporary, *Country Life*, has received from an expert fruit-grower a letter anent fruit-growing in this country from which I must take some extracts. The first point he brings to notice is that whereas Australia, owing to the skill in which its fruit exhibit was staged at Wembley, was able to sell 1,500 tons of apples during the exhibition and take orders for another 50,000 cases or (at around 40lb. per case) 890 tons, this country was entirely unrepresented in fruit. He says:

"The Australian fruit merchants did well at Wembley. They might have done much better had their prices been more reasonable. A shilling for four not over large apples is a high price and works out at about 50s. per bushel. Still, I am not writing to complain of this, but to point out the remarkable circumstance that this Old Country had no such exhibit, and a visitor, while he might obtain Colonial fruit, could not sample our native product. It does seem a pity that our fruit-growing industry did not put up an exhibit, commencing with strawberries, and continuing with cherries, plums, pears and apples. The fruit would doubtless have sold as readily as did the Australian apples, and there would have been no difficulty in getting any quantity sent in daily, with prices ruling proportionately half what the Australian apples fetched."

This proves more than any other statement the lack of co-operation between our fruit-growers. It is no use crying over spilt milk and lamenting the lack of an exhibit of fruit grown in the British Isles; one can only hope that if Wembley materialises in 1925 there will at least be an exhibit of home-grown apples. The correspondent goes on to say that the fruit-grower at home philosophically allows imported fruit to take the foremost place in our markets and agrees to take a lower price for his produce. What an admission! He follows with the remark that grading apples is no more difficult in this country than abroad, which is also true, if you have a central authority, but it is little use individual growers grading apples according to their own ideas, for grading is essentially a method to be used in mass production instead of by individual orchards.

What is of importance, however, is the correspondent's frank statement that a glut year is a bane to the producer of home-grown apples. He says:

"The heavy crops of fruit experienced in what are termed 'glut' years are a bane to the grower. Prices generally drop to a level which necessitates a good deal of fruit being wasted. Growers generally declare that a half crop is more profitable to them than a full crop, and it seems curious to observe growers cultivating, spraying and otherwise treating their trees in the effort to get the best crop possible from them, while in the light of past experience they realise that if their efforts are seconded by a favourable season their crop will fail to compensate them. Yet the overseas grower never fears a glut. If his crop is greater he exports more. Here, then, is the solution of the problem of gluts. Why should we not export? At the time our fruit begins to ripen we have the markets of Australia, South Africa and New Zealand open to us. All the year round India, Ceylon, Egypt and the Farther East would take English fruit and be glad of it. The writer has spent time enough in the Eastern Tropics to know how an English apple would be regarded. South Africa sends us, in perfect condition, such fragile fruit as peaches. She has successfully landed cherries here. It is therefore quite feasible for us to export not only apples and pears, but also cherries and plums, which glut our markets more frequently than do apples."

This appears to me to be the crux of the whole problem. Growers in this country, as well as elsewhere, must work on some kind of an average market. Abroad in an average year a certain amount is allotted to home consumption and the rest to export; if the crop is larger than the average, the additional amount is added to export. In this country the export trade is so small that any additional crop has to be sold in the home market with a consequent glut and drop in prices. This is an eventuality against which home growers as individuals cannot compete. It is certainly a case for a combined society of fruit-growers. Owing to special conditions it is only a combined body of growers who could hope to establish a recognised export trade.

The last extract is as follows:

"Our fruit is said to possess a softer and more tender skin than Colonial fruit and to be consequently less suitable for export. Is this really so? The writer last year sent a box of apples by ordinary parcel post to tropical Africa, with a request that it be opened, the contents examined and reported on, and then repacked and returned. Three kinds of apples were sent. The parcel arrived back with a report after seven weeks. One apple reached its destination in a faulty condition. The remainder did the return journey and were kept by me for weeks in perfect condition. This was by ordinary parcel post method of sending."

This is fairly good proof that the fable, so far practically universal, that home-grown fruit is unsatisfactory for export purposes, is proved to be untrue. More exacting conditions than the despatch of fruit to tropical Africa and its return to this country could hardly be imagined. And yet two apples out of three stood this exacting test. E. H. M. C.

LATE AUTUMN IN THE ROCK GARDEN

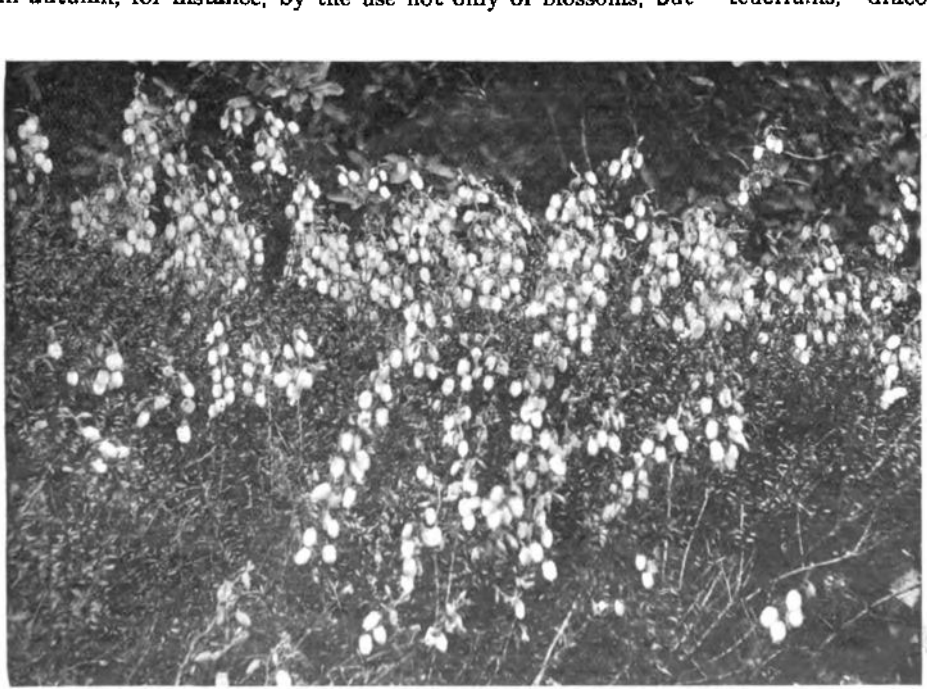
BY DR. R. LLOYD PRAEGER

SEDUM EWERSII WHICH MAKES A BRAVE SHOW WELL ON INTO THE AUTUMN.

SOME twelve months ago in a gardening contemporary Mr. Clarence Elliott wrote under the above title, and he wrote wisely and well. He pointed out that we should not mourn the absence of a blaze of flowers in the rock garden when the year is dying; those facile triumphs of spring are easily attained; but the autumn and winter are the periods which supply the true test of the rock gardener's skill. Then the general lay-out, the placing of rocks, dwarf shrubs, and evergreen cushions and carpets (things much more difficult to carry out satisfactorily than the mere planting of masses of aubrietias and campanulas) come to the front and attain primary importance; it is only when the rock garden retains its effectiveness and interest throughout the short days that we have a right to indulge in self-congratulation over the winter fire.

With what Mr. Elliott says about the rocks, with their mosses and lichens, and the dwarf shrubs and evergreens, all rock gardeners will agree—or ought to. But later on there occurs a sentence which merits discussion, and which, indeed, has inspired these random notes. "It is neither right nor natural," he says, "that there should be many flowers in the rock garden in late autumn or winter." That comparatively few plants bloom at the season mentioned is, of course, true; but the sentence seems to contain a hint that there is something improper about the flowering of plants in autumn, and that propriety should forbid any attempt on our part to brighten the rock garden at that season. Mr. Elliott does not intend to convey that impression, of course, but nevertheless the sentence will serve as text for a short homily on the subject. It will be admitted that it is not desirable to import into the rock garden things that are not rock plants because they are autumn bloomers; that would not be cricket. But, on the other hand, it is highly commendable to brighten and decorate the place at all seasons of the year by the wise employment of all available rock plants: in autumn, for instance, by the use not only of blossoms, but of berries and other fruits, the bright tints of fading leaves, and so on.

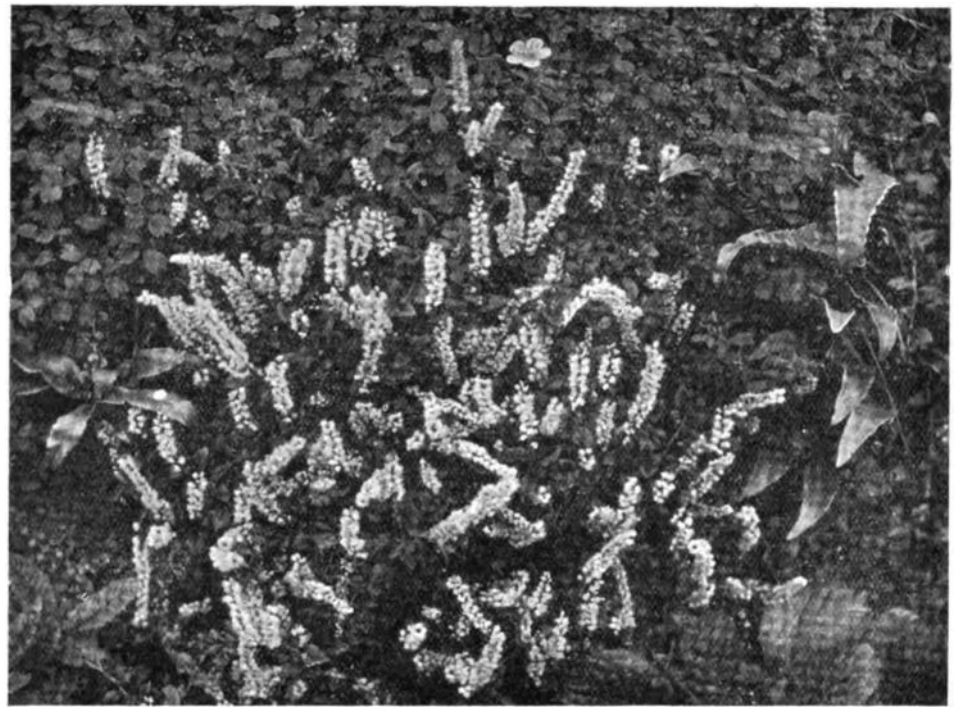
There is, as a matter of fact, a considerable amount of material available to help us at least as far as the beginning of November. After that a period almost hopeless as regards bright colours, stretche still February, when the first kabschias come to our assistance. In September there are a good many distinctive things available, in addition to the many late summer plants which linger long in bloom, and the earlier summer treasures which have such a cheerful way of bursting forth for a second display. The later sedums, for instance, such as S. Telephium, S. Ewersii, S. populifolium and S. spurium splendens, make a brave show, while S. spectabile and S. Sieboldii—two most valuable plants—run away into October. There are a good many quiet little labiates, too, mostly agreeably scented, which are late bloomers and are not seen as often as they might be—scutillarias, satureias, teucriums, dracocephalums, micromerias and origanums. Among the most pleasing of these are Satureia pygmæa, Scutellaria baicalensis, Micromeria piperella and Origanum pulchellum. But many flowers run on much later than these, especially in a mild place. The following, as well as others, may often be seen in full bloom in October should the season be favourable: Parochetus communis with its beautiful blue pea flowers, Erigeron mucronatus covered with white and pink daisies, the dainty Fuchsia thymifolia and other dwarf fuchsias, Œnothera macrocarpa and other prostrate big-flowered evening primroses, Teucrium Chamædrys, St. Dabeoc's heath (Dabœcia polifolia), red, white and parti-coloured, has a way of flowering abundantly in late autumn. Then there are several knotweeds that are most valuable in autumn—Polygonum Brunonis, P. vaccinifolium, P. Emodi. And Senecio lobata is still a mass of little yellow stars in October, even though it may be killed by frost in November. Crassula sarcocaulis is quite hardy in the milder parts of the British Isles, and makes a sturdy little bush covered with pink bloom in autumn. Among the grasses Apera arundinacea should not be forgotten, with its misty



THE ST. DABEOC S OR IRISH HEATH, WHICH FLOWERS ABUNDANTLY IN LATE AUTUMN.

Digitized by Google

waterfall of threadlike stems and its leaves turning redder as the season advances. Euphorbia biglandulosa is a valuable winter ally with prostrate stems bearing glaucous leaves and golden flower-heads. Ceratostigma plumbaginoides is a gem, very late blooming, so that the delicate blue flowers synchronise with the bright tints of its fading leaves. Erica carnea is a frank winter flowerer, and in its many varieties it is a host in itself; and we must not forget the periwinkles, though they are a bit too rampant save for rough places. In the scarlet-flowered Zauschneria californica, again, we have a plant which continues blooming till frost interferes. Finally, there are two saxifrages which must rank among the best of all October flowers—S. Fortunei and its near ally S. cortusæfolia, lovely things with sprays of white bloom. But though these two plants are quite hardy, liking a damp place, the flowers are easily ruined by frost, so we must exercise care in discovering a spot for them where some protecting canopy will shield them.



AUTUMN FLOWERING KNOTWEED FOR THE ROCK GARDEN, P. VACCINIFOLIUM.

A due attention to foliage will greatly enhance the effect of colour in the garden. There are, for instance, a number of dwarf ericaceous things whose leaves turn to beautiful shades of red as winter comes on—Leucothoë axillaris and Oxycoccus macrocarpus, for example. The dwarf cotoneasters are invaluable in the same way, producing really vivid effects—C. adpressa, C. humilis, C. horizontalis and so on, and the scarlet of their leaves is only outshone by their scarlet berries.

There are many other plants whose leaves assume decorative colouring in winter. Some of the heuchera species turn deep red; there is also a form of London pride whose old leaves blaze an unexpected crimson. In contrast to the reds we can work in many beautiful grey and silvery tints by the judicious placing of dwarf species of achillea, helichrysum, pyrethrum and so on. When to these is added the fresh green cushions of the mossy saxifrages, etc., and the darker green of dwarf conifers and other evergreen rock garden shrubs, we may feel that even in November the rock garden may be a place of beauty, an inspiring, not a depressing spot.

GARDEN DESIGN

EVERYONE has his or her own favourite plants, and such personal tastes should be studied and provision made for their gratification in the general design of the garden. The exigencies of any site must be considered, and there are many factors—the architectural character of the house, aspect, the nature of the soil, and particularly the beauty or otherwise of the surroundings—that will have much influence on the general treatment.

To the plant lover there is something very appealing in being able to plant and tend his or her own favourite plants, to watch their habits, to give them better conditions if they show signs of ill health or unsuitable environment, and to group them with a nicety of arrangement that might be impossible with the masses in the larger gardens and borders, where work must necessarily be left very much to the gardeners.

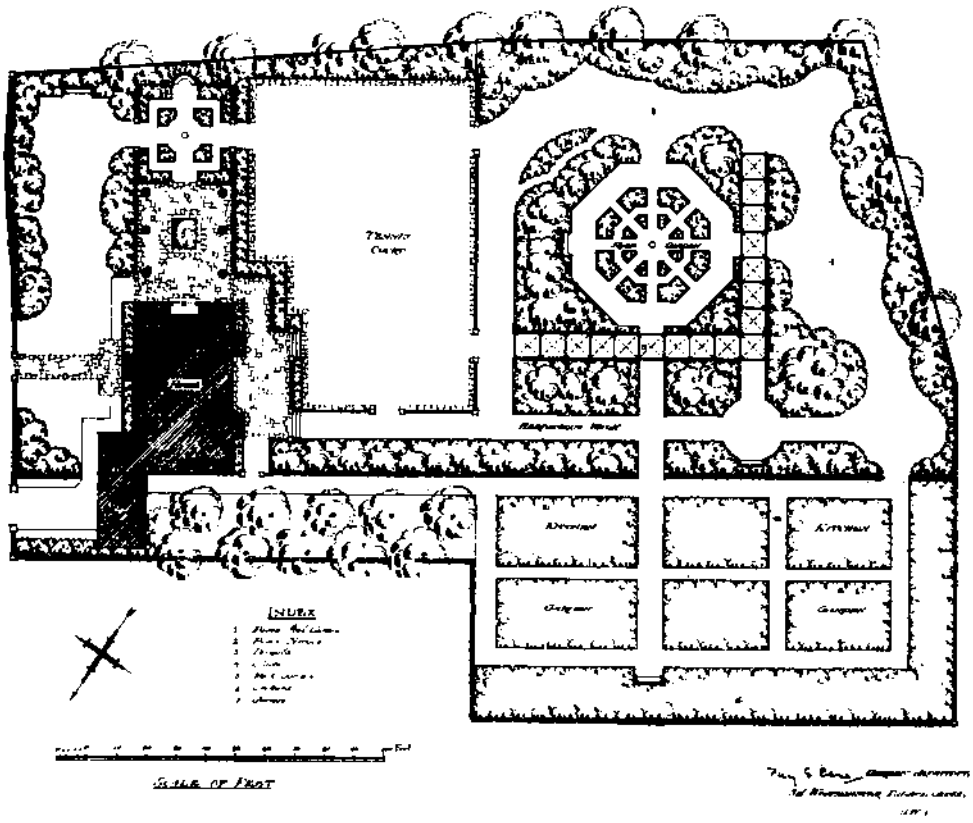
To be able to do this one may have a garden in miniature of whatever character one likes best, set accessibly in the gardens proper, or, where space is very limited, the whole garden will necessarily be rather in the nature of a miniature garden.

Good proportion is always the basis of successful design, and the smaller the

A SMALL TOWN GARDEN OF EXCELLENT DESIGN.

Digitized by Google

garden the smaller must be its component parts. This applies not only to the different gardens but equally to the masses of trees, shrubs and plants that furnish the beds and borders. In extensive grounds it is difficult to give that close care and attention to detail that can make the quite small garden so interesting and so beautiful. For, like a painting, the



miniature garden must be perfect in its tininess or much of its attraction is gone.

One will like to have such a garden near the house and with dry paths so that one can get to it easily at all times and in all weathers. Although it is a pleasure there has been little opportunity to enjoy this year, there is something delightful in the scent of newly rained-on soil and grateful foliage, after a spell of dry weather; and flagged and other paths that dry quickly allow one, if one cares, to be out even while it is raining.

The whole of a town garden is often so small as to be nothing but a miniature garden; but where there is more room this small intimate garden should be so related to its surroundings and so much a separate unit that its tininess does not suffer by contrast with the bigger surrounding spaces. It must always be something in the nature of a toy, but it can be a very beautiful and a very interesting toy.

A sense of proportion and fitness will prevent one from making mistakes in the small garden. One may have a tiny rock garden and make it very beautiful, while it is more difficult to reduce a herbaceous border or walk. The size and habit of growth of the many rock plants are particularly suitable for small spaces, and one may have so many more sorts without getting a spotty effect. Plant lovers like to have many varieties and to notice the difference in their habits.

Stones also must be carefully chosen and carefully placed and, I might say, sparingly used. However carelessly the stones in any rock garden might appear to be arranged—and they should seem to have come naturally, not to be placed at all—there must be a definite rhythm of line in their arrangement. Nothing can quite rectify the want of this beauty of line if it is not the controlling factor in everything that is done, and its absence, to persons of taste, must always cause unsatisfying results.

From their size, many of the herbaceous plants need to be used in groups; but in the small borders one may have the larger plants singly or in clusters of two or three, with rather more of the smaller ones. In such a garden as I am describing the coarser-growing plants would be eliminated altogether, one stately delphinium can be seen in all its loveliness, and singly one can have the choicest varieties of plants, reserving less expensive sorts for massing in the mixed borders.

Next in importance to the design of the garden—and, indeed, interwoven with it—is the question as to what colours shall be introduced, and of these, as to which shall be the keynote or principal. Choice of colours will be influenced by the surroundings and by personal taste. If there is warmth of colour in walls or paving those flowers of softer shades may be used; but if your garden has a green setting of trees and shrubs you may have more of flowers warm in tone, such as reds, oranges and yellows.

Strong colours must be used with discretion; blues are, as a rule, safe, as also are violets and purples. Reds need more care, for while ruby and wine reds may be very beautiful and used most effectively, some of the harder shades—for instance Geum Mrs. Bradshaw and some of the geranium reds—if they are used at all, need very careful placing.

Nature herself helps us wonderfully with regard to colours. Her families of plants nearly always possess a clear affinity, the tones of the different varieties of one plant generally blending so harmoniously that they may be mixed almost anyhow and beautiful results may be obtained by planting largely the different varieties of favourite plants.

With restraint in the choice of plants and grouping of their colours it is easily possible to have colour schemes very beautiful and full of character and far more expressive of individual taste than the two freely mixed borders can ever be. And it is nicer to have character in your colour effects and to vary it from year to year, and have two, or perhaps three, definite successive colour schemes in the same year, than to have an uninteresting succession of mixture succeeding mixture. No one would do this in their rooms, and why should it be done in gardens? Once the keynote of the rooms is struck by wall paper, floor covering or curtains, it is carried out with good contrast or harmonious blending; and this can equally as well be done with plants and flowers.

In small perhaps even more than in larger gardens there can be very distinct changes in the course of the year. A cream and yellow garden of daffodils and narcissi, or a garden in which pink and red tulips predominate in spring, may change to a garden of blue or blue and lavender and grey in the summer.

Then again, in autumn one likes colouring that in the stronger lights of midsummer would seem crude. Autumn lights are softer and in themselves tone strong colours into pleasing harmonies. The yellows and bronzes of sunflowers and heleniums, and the scarlets and ambers, mauves and heliotropes, and many other shades of dahlias resplend against the reds and bronzes, oranges and yellows of dying foliage are welcome to the very last.

No such strong-growing plants as verbascums, sunflowers, rudbeckias, heleniums, etc., will be allowed in this tiny garden of choice things, the pattern of which will everywhere be close and rich like that of Chinese porcelain or Persian rugs. Dwarf-growing campanulas, thymes, menthas and mossy saxifrages will be planted in their many varieties, as will also many of the dwarfer bulbous plants, Iris reticulata, I. Histrio, I. Histrioides, Chionodoxa Luciliæ, Muscari Heavenly Blue, Erythroniums, Fritillaria, Narcissus triandrus, etc.

Digitized by Google

In the plan given is illustrated a design for a garden with sufficient space for a tennis court and several gardens of distinct character. The pergola partly encloses a small rose garden, each bed of which is planted with bushes of one variety only.

Tennis may be watched from the flagged terrace, which is two or three steps higher than the tennis court, from which it is divided by a low flat stone-coped wall. As in so many town houses, the garage is at the side, with a short straight drive to the road. There is no forecourt, a flagged way leading from the gate to the principal entrance. This is more convenient and effective than trying to make a forecourt or drive for a car where there is not the proper amount of space. A small kitchen garden and an orchard enable the choicer vegetables and fruit to be grown, and the surrounding glade, itself a interesting and beautiful walk for the greater part of the year, gives with its taller planting of trees and shrubs enclosure and privacy to the gardens.

PERCY S. CANE.

ARISTOLOCHIA ELEGANS

THIS SPECIES IS ONE OF THE PRETTIEST IN THIS GENUS OF CHOICE PERENNIAL HERBS OR SHRUBS, MANY OF WHICH ARE CLIMBING AND REMARKABLE FOR THEIR VERY ODD SHAPED FLOWERS.

ARISTOLOCHIA ELEGANS is one of a numerous class —tropical plants that do *not* need "stove" conditions. This is emphasised, because the usual relegation of this charming plant to the category of stove climbers may well have deterred many with limited accommodation from attempting its cultivation. Here it is quite at home trained over the roof of the warmer end of a 20ft. span-roofed house with a minimum temperature of about 50° Fahr.

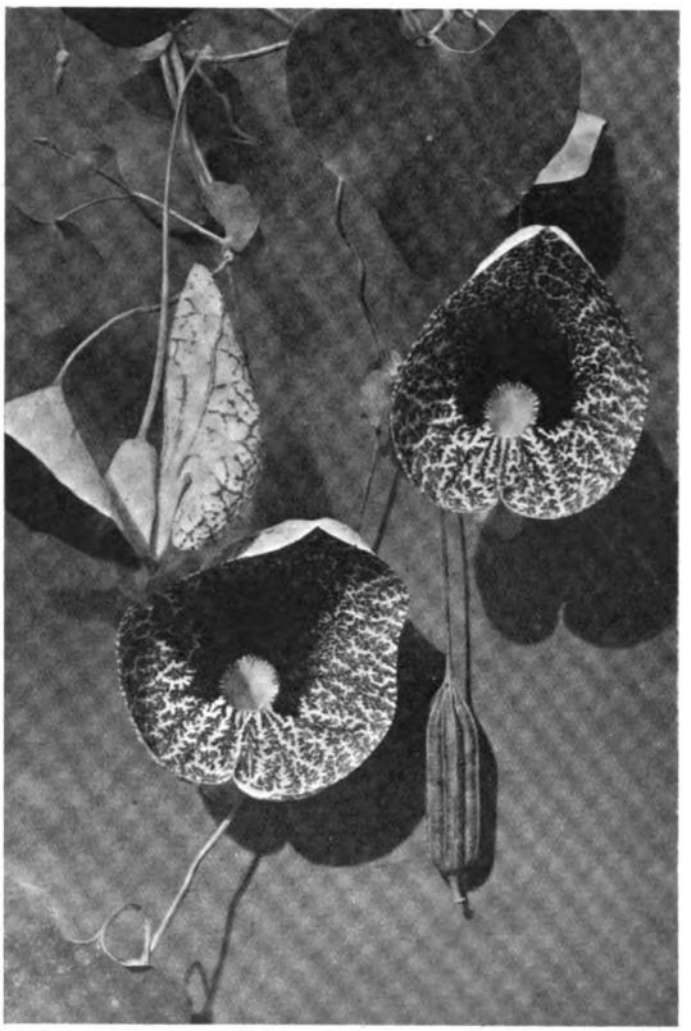
Aristolochia elegans is a rampant climber. Success with it in a confined space depends upon drastic pruning, which treatment is facilitated by the fortunate circumstance that the plant blooms on the current year's growth.

The writer's specimen is planted out in the border of the house, the soil being a light loam, very well drained, and containing a considerable admixture of mortar rubble—there is no evidence that this is necessary. Annual top-dressings of well rotted manure have been found to encourage profusion of bloom.

The plant was raised from seed some eight years ago. The seeds germinate well. Seedlings potted on in a rich soil and trained up light canes have bloomed in 6in. pots during their second season. It is best, however, to plant out in the border.

The plant is of shrubby growth, the old main shoot, which is retained from year to year, being covered with a corky bark, deeply and curiously cut. This shoot has been allowed to grow some 10ft. long. From it new growth comes each spring, twining along the wires and soon covering the roof, obviating the necessity for shading. As winter approaches the season's growth is cut back right up to the main shoot. Thus the plant is kept within bounds; while scale, which at one time gave considerable trouble, is prevented—for the scale insect attacks only the ripened wood as yet without bark, both young shoots and the bark-covered old stem being immune.

The young growth is of palest green. The heart-shaped leaves, from 2ins. to 3ins. in diameter on strong shoots, are produced with internodes varying from a few inches to a foot or more. We usually have the first blooms in July, flowering then being continuous through the summer and early autumn.



A MOST DESIRABLE DECORATIVE CLIMBER FOR A WARM GREENHOUSE.

The strangely shaped flowers, and buds perhaps even more strange, besides provoking the curious, have a very real charm for the plant lover. The colour on the outside is very pale green, on the inside of the flower cream heavily marked with deep velvety chocolate-purple. The intense pale green of the throat contrasts with the deep surrounding colour, while the purple markings extend in fern-like reticulate pattern over the inside of the flower, the deeper veins showing through and relieving the pale green of the buds. The flowers, which are from 3ins. to 4ins. across in the perpendicular direction, are pendent, the buds being produced near the ends of the new growth; though the growing point may have advanced a foot or more before the flowers expand. With us, Aristolochia elegans is a prolific bloomer, producing hundreds of flowers during the summer months. The flowers are without appreciable scent. If any part of the plant is crushed a rather disagreeable odour is apparent; this, however, is not normally noticeable.

Owing to the peculiar shape of the flowers they can be placed in water only in an inverted position. When cut flowers are required, this difficulty may be overcome by introducing a few spots of water into the throat of the flower. The blooms will then keep fresh for a day or more.

It is illustrative of the comparative hardiness of the plant that shoots, forcing their way between a badly fitted glass at the top of the roof, have escaped into the open air and there produced flowers and even seeds.

Comparatively few seeds set. This may help to prolong the flowering season. The six-celled inferior ovaries are apparent only on careful inspection until the fertilised flowers fall. The stem then swells rapidly to a green pod some 2½ins. long, which finally becomes brown and, splitting from the top, reveals the flat scaly seeds.

Should this note inspire in any reader more than a passing interest in Aristolochia elegans, the writer would be happy to further this interest to the extent of supplying a few freshly gathered seeds, of which he has this year some dozen pods.

J. BERTRAM WARD.

GENTIANA GENTILIS

A CURIOUS ANNUAL GENTIAN WHICH, UNLIKE MOST MEMBERS OF THE GENUS, IS PRACTICALLY UNAFFECTED BY LIGHT; ON THE OTHER HAND IT IS EXTREMELY SUSCEPTIBLE TO CHANGES IN TEMPERATURE. SO FAR IT IS RARE IN CULTIVATION, BUT IT IS HOPED THAT IN A YEAR OR TWO IT WILL BECOME BETTER KNOWN.

AMONG the many fine plants which have enriched the horticultural world by the botanical exploration of the Chinese province of Yunnan by Mr. George Forrest in 1910 was Gentiana gentilis—a plant first collected by the Abbé Delavay about the years 1884-85, and was named and described by Franchet in Vol. XLIII of the Bulletin Societée Botanique France, published in 1896.

This beautiful gentian is an annual and has, according to Franchet, much in common with the one he named primulæflora, and which was also collected by the Abbé Delavay as early as 1882. Franchet's name and description have been published in Vol. XXXI of the Bulletin.

Now in Vol. IV of Notes from the Royal Botanic Garden, Edinburgh, we find among a list of new gentians, described by Professor Bayley Balfour and Mr. George Forrest, one called G. leptoclada, which, as the authors remark, has resemblances to G. primulæflora of Franchet.

Dried material of both gentilis and leptoclada are uncommonly like varieties of a common type, and may it not be possible that were more material available for comparison, both would resolve into the earliest found plant—the primulæflora of Franchet.

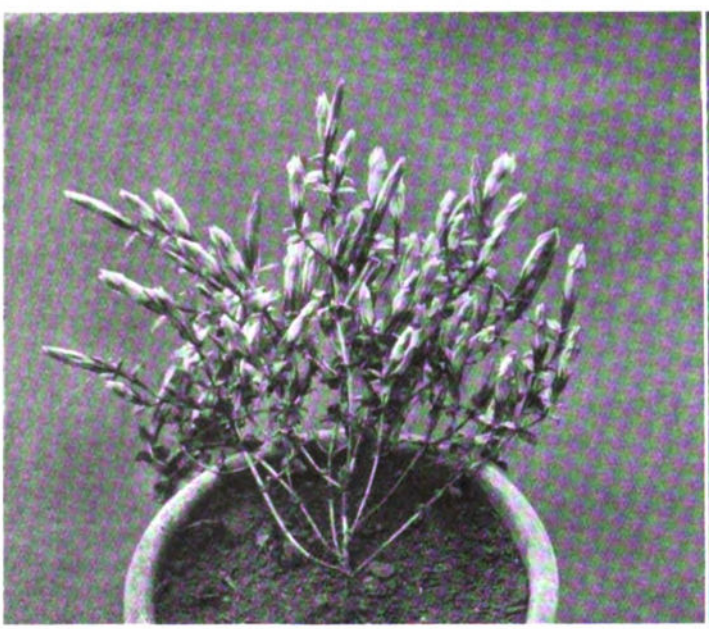
The first record of G. gentilis in flower in Britain was in the summer of 1912, when specimens were to be seen in the garden of Mr. Bulley in Cheshire, and in the Botanic Garden at Edinburgh. These plants were raised from seed gathered by Mr. Forrest the previous year in the Lichiang Valley at elevations between 7,000ft. and 8,000ft.

Fate however was against the efforts of the growers to establish a race in cultivation at that time, and shortly thereafter the plant disappeared. Thanks, however, to the redoubtable Forrest, who was out again in the same region in the interests of Mr. J. C. Williams during the years 1921-22, a further supply of good seed was secured and once more re-established the gentian in cultivation. From this supply of seed several fine plants were raised last year in the Edinburgh Botanic Garden at first indoors, then later planted out in the rock garden when they grew and formed neat compact plants 4ins. or 5ins. in height and some 10ins. in circumference.

As the plants were coming into flower at the end of October, 1923, one was lifted and potted, and thereaft[illegible]ade to complete its life cycle under glass. To this treatm[illegible]t responded, yielding in due season fruit and seed, and as the plate testifies, a plant of exceptional beauty.

Those plants which remained out of doors did well, enjoying as they did the extraordinary fine autumn days of last season bore flowers until the end of November. The colour of this gentian in cultivation is of a distinct pale prussian blue, and in no degree approaches the gentian blue hue of so many flowers of its genus.

While the flowers possessed a colour charm they had in addition a most entertaining habit of closing up on the slightest exposure to changes of temperature. An instance of this susceptibility occurred during the process of carrying a specimen in full flower across a distance of some 100yds. The plant in question had been growing in a cold frame, exposed to the north, and without direct access to the sun. The difference between the air temperature outside and inside of the frame was 10° Fahr. Within three minutes after exposure to the outside air, all the fully expanded flowers had closed up. The plant was thereafter taken to a room where the temperature was 52° Fahr. The effect of this change was not apparent for some time, but gradually the flowers expanded, and ultimately, after an interval of one hour, all were fully opened as before.



GENTIANA GENTILIS WITH CLOSED FLOWERS.

THE SAME FULLY EXPANDED

A second exposure to the outside air temperature—this time 15° Fahr, below the room heat, witnessed a repetition of the movement. During the first minute and half no visible change was observable. There then followed a gradual infolding movement of the corolla lobes, which continued to increase in speed rapidly until a few quick jerking movements signalled the final stage in the movement. The whole operation was completed in three minutes.

The behaviour of the plant was so fascinating that this cruel treatment was meted out to it several times daily for some days. And only as the flowers appeared in turn to be fertilised did their response to the temperature stimulus cease.

A test of the effect of light met with slight response. A fully expanded plant in full flower after eighteen hours in complete darkness at room temperature had no flowers so tightly closed as when exposed to outside conditions as described.

One would infer from the foregoing that this delightful addition to the already known gentians is a highly specialised plant and one tuned to withstand frequent fluctuations of

Digitized by Google

temperature. Arctic cold the one minute to be succeeded by summer heat the next. The plant's native habitat suggests no such extremes—only between 7,000ft. and 8,000ft.—really a sub-tropical zone. It is therefore surprising to find, and difficult to suggest a reason for this plant's remarkable and efficient mechanism for self-protection against heat and cold: a device more to be expected from plants accustomed to dwell away up on the borderland of the eternal snows and at heights ranging up to 14,000ft. Some other explanation, however, may be forthcoming once the plant has become more familiar. The plant is easy to cultivate and thrives in a compost of good loam with plenty of moisture.

It is advisable to sow early and plant out in May. This procedure ensures that the plants will come into bloom in early autumn when the conditions are most favourable and the chances of failure to secure ripe fruit and seed are lessened. R. M. ADAM.

CURIOUS ORCHIDS

BY GURNEY WILSON.

[The orchids as a genus are one of the most outstanding in the plant kingdom, largely owing to their curious forms, which Mr. Gurney Wilson so well describes. The nature of the floral parts of an orchid, with all their modification and their method of insertion on the axis, is one of the clearest evidences nature gives of the intimate relation which exists between the plant and the insect worlds. One of the basic laws of botany and zoology is the apparent correlation which exists in all organisms between form and function; such is exemplified especially in the more highly evolved races of our flowering plants, and none more so than in the case of the orchid.—ED.]

IF the orchid family is rightly noted for the elegance and beauty of its flowers, it is equally remarkable for the many floral curiosities distributed throughout the various genera. Under the title of Curious Orchids it is the species that come more especially under our consideration; plants that not only proved of considerable interest to our forefathers, but which will always be associated with the early-day struggles of orchid collecting and its accompanying dangers.

The Masdevallia genus of South America contains many species whose flowers are noted as much for their grotesque shape as for their extraordinary colouring. An examination of the flowers of M. Chimæra, and its several allies, will indicate why this generic name was selected, for the Chimæra of mythology was a monster that had the head of a lion, the body of a goat, and the tail of a dragon. The three sepals of this flower are oftentimes prolonged into slender tails 4ins. in length. M. Gargantua produces flowers having the hairy lip tongue-shaped and which emit a strong fetid odour, while M. velifera bears flowers that resemble the gaping mouth of an animal, and equally malodorous.

M. fenestrata, now included in the genus Cryptophoranthus, was one of the many orchids that interested Darwin. It is often referred to as the Window Orchid, for the three sepals cohere together and never open. There are, however, two minute oval windows opposite each other, and these afford the only entrance to the flower. Without these windows it would be impossible for insects to reach the reproductive organs, and thereby effect fertilisation. M. simula may be included here on account of its gem-like flowers, which are surprisingly beautiful when seen through a small lens scattered among the grass-like foliage. It is commonly described as the Partridge in the Grass.

The genus Oncidium affords several remarkable species. In O. Papilio the large flowers are carried on straw-like stems 2ft. in length, that bend gracefully to and fro with the forest breeze, the gorgeous gold and reddish-crimson colouring of the butterfly-like flowers producing a realistic effect. Another member of the genus of almost similar characters exists in O. Kramerianum.

Passing on from butterflies to birds, the well known Peristeria elata, a native of Central America, yields scapes that often grow to a height of 6ft., the uppermost part bearing wax-like flowers whose central organs closely resemble the form of a dove, hence the descriptive name Dove Orchid. A specially attractive object to children are the Punch and Judy Orchids, botanically known as Gongora species. In these fantastic floral structures, the labellum resembles the form of Punch, while the column and two petals take the form of Judy waiting to embrace him with outstretched arms. Gongoras are from somewhat tropical localities in Central America and on that account require a warm greenhouse for their successful cultivation.

In the earliest days of orchid history, the treatment of the genus Stanhopea was not fully understood, for although the plants flourished well, the flowers rarely presented themselves. By chance a pot containing one of these plants was broken, when, strange to relate, the flower spike was noticed among the crocks, endeavouring to find its way through the base. The secret was thus discovered, and ever afterwards this genus of plants has been cultivated in light baskets, or in shallow pans having several large holes in the base, so that no impediment may be placed in the progress of the flowers, for it is now fully recognised that they are produced on pendulous stems that hang vertically from beneath the plant. S. Tigrina, a Mexican species, is the most noteworthy representative of the genus. Its large flowers, of thick, wax-like formation, have tiger-looking markings of reddish-crimson colour, while the middle portion of the lip bears two sickle-shaped horns

From the Philippines the charming little Platyclinis filiformis is received. Although the pseudo bulbs are scarcely an inch in height, the slender, almost thread-like racemes bear countless flowers of bright canary-yellow colour, as evenly arranged as the links of a long chain in pendulous condition. Amateurs often refer to it as the Golden Chain Orchid. It requires a hot-house for its cultivation during the growing season in summer, a period when the delicate and fragrant flowers are also produced. Another elegant species whose flowers are arranged on long pendulous stems can be easily grown in Cœlogyne Dayana. It is a native of Borneo, and when in vigorous condition the pendent scapes extend to a length of 3ft., bearing hundreds of yellowish flowers striped with chocolate and brown. It is commonly known as the Necklace Orchid.

The genus Coryanthes, closely allied to Stanhopea, but very much rarer, is truly an orchid wonder. The name is derived from korys, a helmet, and anthos, a flower, in allusion to the helmet-like appendage to the labellum. The flower, sometimes a pair, is borne at the end of a pendulous scape, and is indeed a floral curiosity. The sepals soon wither and take the formation of bat's wings at rest. The fleshy labellum has its lower part converted into a bucket, above which two horn-like appendages secrete sufficient nectar to keep the same about half full of this attraction to insect life. When insects visit the flower they become immersed in the liquid nectar and are only able to escape by crawling through a spout-like aperture in the side, and close to which the male organ of the flower is situated. The bees, or other insects, thus unconsciously remove the pollen when leaving the flower and carry it to the next one visited, when it is placed on the female portion, and fertilisation duly effected. Dr. Crüger, formerly Director of the Botanic Garden at Trinidad, has recorded that some times there are so many of these humble bees assembled that there is a continual procession of them through the passage specified.

While on the subject of insects, we will return to the genus Masdevallia, for in M. muscosa there exists a species possessing peculiar irritability or sensitiveness of the labellum. A small insect alighting on the labellum causes it to fly up with a snap and imprison the same for a period of about fifteen minutes, when it slowly descends and sets free the thief who sought the precious nectar. The point of irritability is only in the yellow ridge of labellum, and the whole process of movement is doubtless one of nature's wonderful contrivances to ensure fertilisation of the flower through insect agency. The excessive hairiness of the stalk and ovary, exceptional among cultivated Masdevallias, is probably intended to prevent insects from crawling up, or otherwise entering the flower by any other means than the spring-trap entrance.

A WILD GARDEN

MANY READERS MAY HAVE A PIECE OF WASTE GROUND WHICH CAN BE UTILISED FOR A WILD GARDEN. IN THIS ARTICLE A READER GIVES HIS OWN PERSONAL EXPERINCES OF THIS TYPE OF GARDENING

AS a beginner may I give fellow beginners a list of plants which I find do well in a wild garden. In my own wild garden, which consists of an acre or so on the Dorset coast, there is a small chalk brook which is a great help. The soil near the brook is damp, but as the ground rises steeply on both sides it becomes lighter and drier. As far as possible I make use of plants which require the minimum of attention, need no staking or division, are slug free, and not particularly attractive to the occasional rabbit which is sure to get into the enclosure. Large plants for the damper and shadier portions include any of the following:

Gunnera manicata.—To grow this 10ft. to 12ft. high it requires space and a good mulch of leaves and a little bone meal in winter. After a few years the plant develops several crowns, which should be hacked out and reduced to one or two.

Rheums in variety.—These are handsome plants in their early stages of growth, but get untidy after flowering.

Aralia Sieboldii.—These plants like moderate damp and shade and plenty of space to develop.

Rodgersia.—These are splendid plants especially R. atro-rosea, R. pinnata alba and R. tabularis. The last-named must be placed where it is sheltered from rough winds otherwise the peat leaves become torn and unsightly.

Saxifraga peltata, Kirengeshoma palmata, Artemisia lactiflora, Primula Bulleyana and P. japonica, Myosotidium nobile and Meconopsis Wallichii are desirable plants, but expensive to buy and apparently short-lived. The last named plant yields abundant seed which quickly germinates in a cold greenhouse.

A few of the ferns I like best are the common hart's-tongue, Woodwardia radicans, lomaria, a rapidly spreading fern, and Osmunda regalis.

Petasites japonicum is a tropical-looking plant and must be placed in a very sheltered position. Unfortunately, slugs are partial to it; this applies also to all the senecios, except possibly S. pulcher, which thrives well in a sunny situation.

THE IMPOSING HYACINTHUS CANDICANS WHICH GROWS SPLENDIDLY IN ANY SOIL WHICH IS NOT TOO HEAVY.

Astilbes retain their flowers longer in partial shade, but give trouble as they require frequent division.

Eryngium bromeliæfolium and E. pandanifolium have a tropical appearance and do not like too much shade or damp.

Polygonum sachalinense and P. cuspidatum are dangerous plants. They spread everywhere and are difficult to eradicate.

For covering stones and rocks Arenaria balearica is excellent. It requires shade and damp otherwise it becomes yellow and unsightly.

Shrubs and trees are rather too wide a subject to deal with, but I think if limited to eight varieties I should choose, for partial shade, Tricuspidaria lanceolata and Hydrangea Mariesii. As foliage plants on drier and sunnier ground, Azara microphylla, Pittosporum Mayii, P. Tobira, Arundinaria nobilis, A. nitida and Dracæna indivisa, are all good. For flowering shrubs in sun Helichrysum rosmarinifolium, Senecio Grayi or Ceratostigma Willmottiæ, could be chosen. These last few shrubs are easily raised from cuttings.

In wild gardens where the soil is suitable for rhododendrons, kalmias or camellias, most of the above-named shrubs could be eliminated, with the exception of tricuspidaria.

On sunny and fairly good ground Phormiums should do well, and I especially recommend the golden, wide-leaved variety. Quite good combinations can be made with Kniphofia Lord Roberts and montbretias and Sutton's orange calendula. On damper ground Monarda Cambridge Scarlet mixed with Achillea The Pearl, gives a good effect; both these plants require frequent division.

Two very easy plants to grow are Telekia speciosa and Thalictrum dipterocarpum; they are long-lived,

GUNNERA MANICATA GIVES EXCELLENT EFFECTS IN DAMP AND SHADY POSITIONS.

Digitized by Google

never require dividing and are most easily raised from seed. A handful of thalictrum seed scattered on a finely dug seed bed at any time during the summer will yield hundreds of plants which can be left undisturbed until required for their permanent quarters. If the seed of T. dipterocarpum ripens this year I will gladly give some to any reader of THE GARDEN who will send me a stamped and addressed envelope.

On the higher and steeper slopes of my wild garden, where the soil consists of chalky earth, Japanese cherries seem to be doing well, also some clumps of Yucca recurva and Beschorneria yuccoides. Where the grass has been cleared away, orange calendula, nasturtium and the dark red valerian seed themselves freely. In places where the ground is well dug Spanish irises and common red tulips make fine patches of colour for a week or so.

I suppose that every wild garden worthy of the name should contain several varieties of lilies. Lily bulbs, besides being expensive not only need most careful planting, but often yield very disappointing results. I think that I have spent more time and back-aching labours in trying to establish Lilium giganteum and the white L. Martagon than any other plant in the garden, and with absolute failure as the result.

L. croceum and L. umbellatum will grow practically anywhere in fairly sunny, well dug ground and L. Roezlii and L. pardalinum do well in damp, shady places. Possibly the cheapest of all lilies is L. regale. Even one flowering plant of this will yield countless seeds which are easily and quickly raised in a frame or cold greenhouse. Of the imported bulbs I find L. tigrinum splendens and L. auratum platyphyllum do very well for two years.

SUITABLE FOR PLANTING IN PARTIAL SHADE, TRICUSPIDARIA LANCEOLATA.

HARDINESS OF SHRUBS ON TYNESIDE

NOW that the planting time for trees and shrubs has come round again a few notes on the hardiness of some of the less common in a small Northumbrian garden may not be out of place. In Northumberland, as a whole, the summers are cool and the springs cold, but the frosts in winter are no more severe than they are in the southern counties north of London. The garden in question is situated on the northern slope of a hill at about the 500ft. level, and about twenty-five miles from the North Sea. In such a garden, vegetation, although slow in starting into growth in spring, is less liable to be checked by late frosts, or cut by early ones in autumn. During still frosts the temperature is never so low as in the valley, but it is always lower on the higher ground if the frost is accompanied by wind. Within recent years the winters of 1912 and 1917 have been the most severe. In 1912 the thermometer was as low as 4° below zero in the valley—the lowest reading for a great number of years. Last winter, though nothing like so severe as 1912 or 1917, was very trying to vegetation on the hill, as the coldest weather was accompanied by a strong northerly wind, and the garden referred to is very much exposed to winds from the north-west, north and north-east. The garden's principal shelter from these winds is given by a low boundary wall on the north, which, owing to its southern aspect, has been utilised for the growing of some less hardy shrubs. The dates after the names indicate the years of planting.

AZARA MICROPHYLLA, spring 1922, against south wall, has grown well and suffered no damage. Its neat evergreen leaves make it a very effective wall shrub where foliage alone is wanted.

BERBERIS SARGENTIANA, 1922.—Though the wood was entirely uninjured the leaves were very much damaged last winter, which gave it a shabby appearance till new growth started.

BUDDLEIA VARIABILIS, spring 1911, has only once suffered more than slight damage by frost, and that was in 1912, when it was cut to the ground—no disadvantage in the case of a shrub of such vigorous growth. B. variabilis var. nanhœnsis, 1923, appears to be just as hardy, and besides its neater growth has the great advantage for cutting purposes of having a sweet scent in place of the disagreeable one of the type.

CAMELLIA LATIFOLIA, spring 1916, in open, was killed 1917. C. japonica C. M. Hovey, 1921, in open, has grown well but not flowered. Probably rather far north for a camellia, for, if it escapes being killed by frost, the summers are rarely warm enough for any flower buds to be formed.

CARPENTERIA CALIFORNICA, spring 1922, at base of south wall, has grown well and passed through last winter all right; flowered this year for the first time. Well worth a little extra care to get it to succeed.

CEANOTHUS "BRILLIANT" 1914, against south wall. This is an evergreen and flowers in June. It has done well and flowers regularly, and last winter the part 3ft. above the shelter of the wall was entirely uninjured by the cold winds. C. azureus Gloire de Versailles, 1912, on south wall, has been a great success.

CHOISYA TERNATA, spring 1911, in open, but sheltered place, has done well and flowered freely every year. Stood the winters of 1912 and 1917 with only very slight damage.

CISTUS LAURIFOLIUS, 1912.—Nothing so far in the way of weather has done this the slightest harm, even in an exposed position, and no shrub flowers more freely and regularly. C. cyprius, 1922, at base of south wall, has not yet had any frost hard enough to damage it. It is a lovely thing, even finer than C. laurifolius. C. rosmarinifolius, 1922, in exposed position, was entirely undamaged last winter. The same cannot be said of C. crispus and C. florentinus, as they both suffered, especially C. crispus.

CLIANTHUS PUNICEUS, 1923, on south wall, despite being covered with a mat during the coldest spell was damaged last winter.

COROKIA COTONEASTER, 1914, has never been hurt. It is more curious than beautiful, and its starry yellow flowers have never been borne in sufficient quantity to make a show.

CUPRESSUS MACROCARPA, 1914, has grown very rapidly and escaped damage by frost, but the first one planted, after getting to a fair size, was blown down owing to its being a pot-grown plant, and so getting its roots twisted.

DESFONTAINEA SPINOSA, 1922, in peaty soil in a rather shady position, has grown well but not yet flowered.

ERICA ARBOREA ALPINA, 1922, in exposed place, was just as fresh and green last April as the autumn before. E. australis, 1915, in open, has done well and though sometimes the tips of its new shoots have been caught, has never suffered much damage, probably owing to its often being covered by snow before a really hard frost. A very fine heath. E. lusitanica, 1914, and E. Veitchii, 1919, have only been slightly damaged.

ESCALLONIA MACRANTHA VAR. INGRAMI, 1908, in open, after being killed to the ground in 1912, was moved to the south wall. Since then has never been seriously damaged and even the exposed part 3ft. to 4ft. above the wall was scarcely affected last winter. E. langleyensis, 1914, on south wall and above is a fine sight every year, with its innumerable red flowers, and its leaves in December, when they turn golden, are quite attractive. E. Edinburgh, 1922, on west wall, does not look like rivalling E. langleyensis for colour effect.

EUCRYPHIA PINNATIFOLIA, 1922, in open, has grown well, but not yet flowered. A few late leaves were retained all through last winter undamaged.

FEIJOA SELLOWIANA, spring 1921, against south wall, has grown slowly, though satisfactorily, and flowered sparingly in 1922 and

Digitized by Google

1923. A mat during hard frost has so far been sufficient protection.

GARRYA ELLIPTICA, 1913, against south wall, has grown or flowered well, and last winter the leaves on the exposed branches 2ft. above the wall were none the worse for their trying ordeal.

HAMAMELIS MOLLIS, 1916, and H. JAPONICA var. ZUCCARINIANA, 1912.—It is wonderful what the flowers of these two will stand in the way of weather. For effect it is hard to say which is the better.

HYPERICUM HOOKERIANUM, 1915, has not grown well. It seems to be slow in recovering from the check of having the new growth that it often produces in February cut back in March.

LEPTOSPERMUM SCOPARIUM NICHOLII, 1921, on south wall, has not done well despite being covered with a mat during all cold weather. Perhaps the position, or the heavy soil in which it is growing, does not suit it.

MAGNOLIA CONSPICUA, 1912, on south wall, has grown well and flowered regularly, but generally loses a number of its flower buds each winter. The same applies to M. stellata, 1913, in open. M. Kobus, spring 1923, in open, is growing vigorously. M. parviflora 1922, is only growing slowly.

MUEHLENBECKIA COMPLEXA, 1918, was a little damaged last winter, but looking at it now no one would think so.

OLEARIA NUMMULARIÆFOLIA, 1921, and O. macrodonta, 1922, in open, have grown well, and were entirely unaffected by the bad weather last winter. O. Haastii, 1902, was slightly damaged in 1912, but lower down the hill this species was then cut to the ground, but so also was the wild gorse and broom.

OSMANTHUS DELAVAYI, 1922, in open, has only grown slowly though apparently unaffected by the cold winds.

PHILESIA BUXIFOLIA, 1921.—Despite still being only a small plant, this and last year, has had three or four of its large striking red flowers. A very desirable shrub for a sheltered shady spot in the rock garden in lime-free soil.

PHYGELIUS CAPENSIS, 1922, at base of south wall, did not lose a leaf last winter and is now flowering.

PITTOSPORUM TENUIFOLIUM, in open, 1923, stood last winter all right.

QUERCUS ILEX, 1913, in a very exposed position, was uninjured last winter while wild gorse near was browned.

RHODODENDRON CILIATUM, 1912, in open, has never been much damaged, and some years has been a very beautiful sight in April when in full bloom, but last year all the flower buds were killed in March owing to being rather far advanced with the previous mild weather. R. rubiginosum, 1916, is also liable to have its buds killed, but not so much so as R. ciliatum. All the following dwarf rhododendrons were uninjured last winter: calostrotum, chryseum, fastigiatum, intricatum, ledoides, primulinum, rupicolum, scintillans and Williamsianum. Of these calostrotum, fastigiatum, ledoides and primulinum are especially fine, and are gems for the rock garden. Chryseum and Williamsianum have not yet flowered. R. moupinense, spring 1922, has lost its flower buds the last two winters just as they were about to open.

ROMNEYA COULTERI, 1920, at base of south wall, has done splendidly.

TRICUSPIDARIA HOOKERI, 1921, on east wall. Uninjured last winter, but was covered with sacking on two or three of the coldest nights.

VERONICA SALICIFOLIA, 1910, in open, has proved hardy and though exposed bushes have had all their leaves browned they soon recovered. A fine thing when in bloom, but has one drawback, viz., that it reproduces itself too readily from seed. V. parviflora, 1913, at base of south wall, has also done well.

VIBURNUM CARLESII, spring 1922, at base of south wall, has grown and flowered splendidly. The flower buds which started growing last February were unaffected by the cold of March. V. fragrans, 1923, the same cannot be said of a small plant of this, as it did not survive, having its new leaves killed in March. V. Tinus, 1904, has never suffered much damage. Instead of making its principal show in autumn as farther south, the main display is in spring.

YUCCA FILAMENTOSA, 1903, has done well and one clump this autumn has four flower spikes, the two tallest of which are about 6ft.

Bamboos, such as Bambusa palmata, Arundinaria japonica, A. nitida, Phyllostachys aurea and P. virida-glaucescens, all passed through last winter very well, and were not really unsightly in April as might have been expected.

R. B. COOKE.

Kilbryde, Corbridge-on-Tyne.

LATE AUTUMN FLOWERS AT VINCENT SQUARE

THE fact that the season is now fast drawing to a close was clearly in evidence at the third from the last show of the year of the Royal Horticultural Society at Vincent Square on November 18th last. The attendance was not large and the exhibits were more or less of a conglomerate nature. The principal features of the Show were the chrysanthemums and carnations, supported by small exhibits of evergreen and hardy shrubs and two exhibits of vegetables. Fruit was represented in a small but well arranged collection of apples by Messrs. G. Bunyard and Co. The other exhibits consisted of paintings, drawings and designs and various sundries of a miscellaneous nature. A few of the drawings were particularly well done and merit the attention of all lovers of wild and garden flowers. In general the floral exhibits are beginning to show the ill-effects of the weather conditions which we are at present experiencing and it reflects credit on the growers who are able to stage a collection of blooms at this time.

The many varieties of chrysanthemums which are robust in habit and which have been seen of even size, form and colour all through the season must surely be more worthy of growing than those which were perfect at the chief show and at other times very much inferior. The time, labour and money spent on the enormous exhibition Japanese chrysanthemums cannot make them of real practical use, their chief appeal being to the exhibitor. The average person wants chrysanthemums of strong vitality, good in colour and form, and which will flower freely with a moderate amount of attention. All the chrysanthemums exhibited by Messrs. Cragg, Harrison and Cragg possessed these qualities and have shown a uniformity of excellence throughout the season. The sturdy growth and good condition of the flowers were particularly noticeable. There was a good collection of varieties of recent and past introduction. The new ones selected were superior to the similar old varieties: it was not a case of another added just because it was new when the old varieties were as good, if not better. Aldyth, a bright rich crimson of the Japanese type, which received an award of merit at this show, thoroughly deserves the attention of every grower. The two best incurved Japanese varieties were A. Brooker, a large red with the reverse side yellow, and P. Dore, an excellent white. Three colours which were somewhat out of the ordinary were the lilac pink of A. Lionet, the deep velvet crimson of Black Prince and the pinkish bronze of Rosalind. The flowers of Black Prince were small and borne on erect stems. Rosalind had large, well-shaped flowers which have the advantage of blooming late in the season. December Gold made a good effect and is still one of the best market yellows. Among the singles the glowing red blooms of Sandown Radiance and the vivid flowers of Yellow Jewel were outstanding.

A complete change and a great contrast are always appreciated. One becomes tired of even the choicest flowers if used for decoration regularly, and anything which is entirely different is given a hearty welcome. It was with these feelings and with surprise that many people regarded the unique exhibit of ornamental grasses and everlasting flowers shown by the French Intensive Gardens, Croydon. The stand was splendidly arranged and it made one realise the value of grasses for decorative purposes and the variety of form from which to choose. Everlasting flowers and grasses remain fresh and look cheerful the whole winter when other flowers are scarce and dear. They are inexpensive and give no trouble, as they need no water. There are only a few which are in general use, for instance, pampas grass (Gynerium argenteum), Physalis Francheti (the Chinese lantern), Helichrysum monstrosum (the old-fashioned everlasting flower), sea lavender, (Statice sinuata) and Echinops in variety. All these were represented in this exhibit, and yet there were many others shown which should be more widely known.

The feathery nature of the grasses and their slight movement in the breeze makes them particularly graceful. The types shown varied in form from the dainty sprays of Agrostis pulchella to the beautiful plumes of pampas grass. Some were pinkish brown in colour, others shaded with green and some white. One of the most attractive was Hordeum jubatum, the squirrel tail grass with its long hairy spikes tinged with green. Lagurus ovatus had soft downy heads known as hare's tail. Briza maxima and B. minima gracilis, two of the quaking grasses, were most graceful. The genera agrostis and bromus were well represented. There were many shapes and colours in the flowers also. Two large bunches of pink flowers were most conspicuous, one being Acroclinum roseum and Rhodanthe maculata. The latter had a yellow eye and a deep crimson ring encircling the eye. The mauve spikes of Statice Suworowi, which were curiously twisted, were noticeable. The well known Helichrysum monstrosum was exhibited in a variety of shades ranging from yellow to deep orange. It is a native of the Cape of Good Hope, and Helichrysum orientale is the much-used immortelle of France. Two good specimens were Ammobium alatum, a small white flower, and Gomphrena globosa, seen in bright orange and magenta. The bluish colour of Echinops Rito was very good and would make striking decoration.

Other exhibits were as follows:

Apples.—Bunyard and Co.

Begonias.—Stuart Low and Co.

Carnations.—Allwood Brothers, C. Engelmann and Stuart Low and Co.

Chrysanthemums.—K. Luxford, Stuart Low and Co., Mr. A. J. Vinten, W. Wells and Co. and K. Wood.

Cyclamen.—Stuart Low and Co.

Gentiana and Schizostylis. — Clarence Elliott.

Kale.—Sutton and Sons.

Digitized by Google

Orchids.—Stuart Low and Co.
Potatoes.—Carter and Co.
Shrubs.—G. Whitelegg.
Violets.—B. Binney, Miss E. Heathcote and J. Kettle.
Landscape.—P. S. Cane and K. and E. Hopkins.
Artists.—Edith A. Andrews, Lady Proctor-Beauchamp, Edith Fisher, Agnes Foreman, Eva Francis, Eva Kirk Patrick, Mrs. Henny Spenser, M. Townsend, Mrs. Russell Walker, Winifred Walker, Ellen Warrington and A. E. Wilkinson.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

CHRYSANTHEMUM ENVY.—This is a fine single variety with dark reddish reflected florets with a yellow base leading into rather a small and inconspicuous eye. Many of the blooms were showing the ill-effects of the weather. Foliage is of a dark bluey green colour. Shown by Mr. J. Barrell.

C. SPORTSMAN.—Another large single variety with blooms made up of tiers of recurved florets of a light red in colour, shading off at the base to a light yellow. The eye is prominent and upraised, setting off the florets to advantage. Shown by Mr. H. Shoesmith, Woodbridge Nurseries, Guildford.

C. CHALLENGER.—Another excellent single variety of a most graceful habit. The flowers are set well on the stems save for a slight twisting. The florets are raised and upstanding from a fairly prominent eye. In colour they are a shade of bronze red shading off to a yellow base. Shown by Mr. J. Barrell, Bridgwater.

C. MRS. J. BARRELL.—This is another single variety somewhat similar to Envy. The foliage, however, is of a lighter colour, also the florets are decidedly lighter in shade. The flowers of this variety have a much more prominent yellow eye raised like a cushion. Shown by Mr. J. Barrell.

C. ANNETTE.—This is an excellent single variety. The blooms are of good shape, composed of many rows of stiffly arranged florets. In colour they are a shade of yellow tinged with bronze round the outer margins. The flowers are borne on stiff stems which carry neat and small foliage.

C. ALDYTH.—A beautiful market variety of a rich dark crimson to maroon in colour, with a bright glow over the flowers. The blooms are of almost perfect shape, very full and are set off to advantage on the erect stems and small neat foliage. The shape is apt to be lost once the blooms are past their prime.

C. LYNETTE.—A really good variety of distinction at this time of the year, with large blooms, 6ins. to 8ins. across, of a beautiful soft white, made up of numerous straight, reflexed and twisted florets. Unfortunately the whiteness gives way to a yellow greenish centre, but otherwise the blooms are perfect. The last three were shown by Messrs. Cragg, Harrison and Cragg, Heston.

C. MRS. R. JINKS.—This single variety is of a unique colour—rather dull buff or fawn—giving way to yellow at the base of the florets. The cushion eye is prominent. The habit appears good although the stems are rather long and leggy—at least, when seen as a spray. Shown by Mr. R. Jinks, Upper Tooting.

CARNATION ANNE CORRY.—A very fine variety with well formed blooms of a dark maroon shade of a delicate and pleasing fragrance. The calyx does not appear to burst. The flowers are carried well on stiff, erect stems and the plant appears to be floriferous. It is undoubtedly a good variety and one which to all intents and purposes will give good results. Shown by Mr. G. Carpenter, Byfleet.

ORCHIDS.

MILTONIA WILLIAM PITT VAR. ATROPURPUREA (Isabel Sander × Bleuana var. Reine Elizabeth).—This beautiful hybrid carried a spike of two large flowers of typical vexillaria formation, but very much deeper in colour; sepals and petals intense crimson-purple, labellum of similar colour, except at the base, which is whitish and rayed with brown lines. The extreme tips of the sepals and petals are whitish, as also is the narrow border to the labellum. From Messrs. Charlesworth and Co., Haywards Heath. First-class certificate.

ODONTONIA REGALIS (Miltonia vexillaria var. Queen Alexandra × Odontoglossum Aquitania).—An uncommon result in which the spike carried three flowers with elongated segments, white, with rose-flushed areas, and slightly marked with blackish spotting. From Messrs. Charlesworth and Co., Haywards Heath. Award of merit.

MILTONIODA BOADICEA (Miltonioda Harwoodii × Miltonia vexillaria).—Although of poor formation, the two flowers borne by this young seedling were remarkable in point of colour, the sepals and petals being intense crimson, the labellum a little lighter. From Messrs. Charlesworth and Co., Haywards Heath. Award of merit.

CHRYSANTHEMUM ENVY, A CHARMING MEDIUM-SIZED SINGLE.

NEW CHRYSANTHEMUMS.

A CONSIDERABLE number of novelties were submitted to the Floral Committee of the National Chrysanthemum Society on November 17th, when awards were made.

CHALLENGER.—A medium sized single chrysanthemum of considerable beauty. The substantial florets are of rich chestnut colour which is enhanced by a yellow zone. First-class certificate. Shown by Mr. J. Barrell.

ELEANOR.—A small single of orange red colouring and a bright yellow zone. The colour is very desirable but the flowers seemed to lack substance. First-class certificate. Shown by Mr. J. Barrell.

ENVY.—A medium sized single of great charm. It is of chestnut red colouring with a narrow zone and a very small eye. First-class certificate. Shown by Mr. J. Barrell.

MRS. R. JINKS.—A lovely single chrysanthemum of medium size, perfect form and dull fawn colouring, with a pale golden zone. Shown by Mr. R. Jinks.

NOVEMBER SUN.—The award to this variety was subject to comparison with British Empire, a variety raised some years ago by Mr. Norman Davis. It is a very useful incurved Japanese variety of medium size and, in habit, inclining much more towards the incurved than the Japanese type. The colour is a bright canary yellow. First-class certificate. Shown by Messrs. W. Wells and Co.

R. HOOPER PEARSON.—This exceedingly richly coloured yellow variety received an award a long time ago as a show flower and now was submitted as a market variety. It is a flattish and very substantial bloom of medium size. Shown by Messrs. W. Wells and Co.

SHEILA.—A medium sized single chrysanthemum of great charm. The colour is a rich ruby crimson and the florets have a delicate "bloom." First-class certificate. Shown by Messrs. Keith Luxford and Co.

SPORTSMAN.—A large well formed single of reddish colour shaded with rose towards the centre, which gives way to a clear yellow. The eye is large, prominent and raised like a cushion, the florets standing out well and showing the individuality of the flower to advantage. First-class certificate. Shown by Mr. H. Shoesmith.

WINTER PINK.—The committee wished to "see again" this market sized Japanese variety. It is a bright flower made up of stiffish florets which are heavily lined with deep pink except at the tips which are paler. The blooms are of fine form and are well carried on the stiff erect stems. Shown by Mr. H. Shoesmith.

ZULU.—The reason for the name is not readily apparent, but the colour is very uncommon; it may best be described as being a purplish magenta, lightly flushed with maroon. Perhaps the committee considered the flowers to have too many florets to be a good single, but its substance and unusual colour will commend it to many private growers. Shown by Mr. Edward Jones

GARDENING IN THE MIDDLE AGES

"Mediæval Gardens," by the late Sir Frank Crisp, Bt. Edited by his daughter, Catherine Childs Paterson, with illustrations from original sources collected by the author. Two vols., 4to. (John Lane, £6 6s. net; limited to 1,000 copies).

"The Old English Gardening Books," by Eleanour Sinclair Rohde, with facsimile illustrations. Demy 8vo. (Martin Hopkinson, 15s. net.)

IN these days, when everyone is attacking the science of gardening with a kind of ferocious zeal, it is sometimes pleasant to look back on days when there was little science in gardening. Then it was a means to an end; the end was repose, a soothing pleasaunce; the means were flowers and herbs mostly collected from the countryside and transferred to a garden. Apart from culinary vegetables, practically every denizen therein was sweetly scented. Did not a Dutchman write in 1560 "their chambers and their parlours strawed over with sweet herbes refreshed mee; their nosegays finely intermingled with sundry sorts of fragraunte floures, in their bedchambers and privy rooms, with comfortable smell cheered me up, and entirely delyghted all my senses."

Although the two books reviewed in this article differ in date and in treatment, yet they both run together in that they delve into the foundations of the modern garden. Perhaps it is unfair to write about them in the same article because "Mediæval Gardens" consists of short notes by the late Sir Frank Crisp with a fine collection of illustrations taken from contemporary manuscripts and books, while Miss Rohde's volume is a finished work written with a sympathetic charm. "Mediæval Gardens" deals with the subject of early gardens from the point of view of contemporary artists. The late Sir Frank Crisp rightly judged that in a subject about which so little is known perhaps a certain amount of knowledge could be gleaned from contemporary art. He collected illustrations of every picture which had even the smallest aroma of a garden even in the background or as a subsidiary subject. His devotion to this collection is worthy of all praise. It is a pity that "Mediæval Gardens" was not handed over to an expert for completion, for it is so obviously an incomplete work. It is sumptuously produced, one of the best that I have ever seen, and the illustrations on the whole are singularly complete, although more descriptive titles could have been given. The notes, however, are unworthy of the book. There is no mention, for instance, of the singular symbolical significance which almost all plants had for our ancestors. It was the heyday of the "doctrine of signatures" when plants were given a medicinal value according to their supposed resemblance to various parts of the human anatomy, and yet this important point is not touched upon. There is a chapter on "Beds and their Sparse Planting," a curious point in all illustrations of mediæval gardens, but there is not the slightest suggestion of a reason for this phenomenon. Why should that title be given to the chapter? Even the editing of the illustrations is occasionally careless. Three plates are duplicated in the second volume alone. On the whole "Mediæval Gardens" is a disappointing book. The illustrations form a marvellous peg on which to hang an enchanting treatise on the beginnings of gardens.

Miss Rohde's book, on the other hand, is full of ripe wisdom. She starts off with Thomas Hyll, who wrote the first book devoted to gardening in England, "A most Briefe and pleasaunt treatyse, teachynge howe to dress, sowe and set a Garden." She then touches on "Tusser's Five hundred pointes of Good Husbandrie," which I think she praises unduly. He used a particularly annoying metre and had little real feeling; in fact, he was a good literary hack. The next author Miss Rohde mentions, one Richard Gardiner, a linen-draper of "Shrewsberie," is much more worthy of attention. He published a book in 1597 dealing entirely with vegetables. There is a particularly charming quotation given about carrots: "Carrets are good to be eaten with salt fish. Therefore sowe Carrets in your Gardens, and humbly praise God for them, as for a singular and great blessing; so thus much for the use and benefit had in the commonwealth by Carrets."

Miss Rohde has an intense and deserving admiration for William Lawson, with whom she begins the next chapter, for he was a particularly charming writer. Here is a sample from his "A New Orchard and Garden": "Store of Bees, in a dry and warm Bee-house, comely made of Fir-boards, to sing, and sit, and feede upon your flowers and sprouts, make a pleasant noyse and sight. For cleanly and innocent Bees, of all other things, love and become, and thrive in your Orchard." Markham, who is mentioned next, was a worse hack than Tusser, and except for a certain picturesqueness of language is of little account; then comes the greatest figure, John Parkinson, who, apart from being a sympathetic man and a charming writer, was also a great botanist. His famous "Paradisus" was founded on the plants he grew in his own garden, and his collection must have been exceedingly large. Nearly a thousand plants are mentioned, most of them exotic. He was also a hybridiser, and I was glad to see Miss Rohde quote his remark about Parkinson's Daffodil: "None ever had this kinde before my selfe, nor did I my selfe see it before the year 1618, for it is of mine own raising and flowering first in my Garden."

And so Miss Rohde wanders through the gardening writers of the sixteenth and seventeenth centuries. From the sympathy with which she treats each individual author and the care with which she selects her quotations I imagine that in these books lies her garden and the rounded quotations are plucked from their pages as others pick a valued flower.

E. H. M. C.

CORRESPONDENCE

BORDER CARNATIONS.

SIR,—On page 746, November 1st issue, Mr. Norman Lambert states: "Gracefulness . . . this is a fine variety for growing under glass, when, with the calyx eased and helped occasionally, it can be grown to a very large size."

What does he (Mr. Lambert) mean by "the calyx eased and helped occasionally"? I have asked other carnation lovers and growers, but they do not know.—LINKMAN.

FRIENDS AND FOES OF THE GARDEN.

SIR,—Among gardeners there must be many who hold divergent views as to the worth of birds of any kind in the garden. Some, indeed, have nothing to say in their favour; rather do they look upon them as a trial which has to be endured; while others, if they do not regard them in the light of enemies, shut their eyes to the help they are, especially in the summer and autumn, in the extermination of numerous pests which would make greater inroads on crops were it not for certain members of the feathered tribe. And they are prejudiced against birds, inasmuch as, like some of us, they have suffered through their depredations in strawberry beds and cherry trees and, possibly, bush fruits in general.

Mr. Clifford W. Greatorex, however, makes a very good defence in the case of the birds referred to in his informative and interesting article in THE GARDEN for November 8th.

Wrens and robins, as well as thrushes, are very busy in the garden in these late autumnal days, and if statistics could be furnished of only one day's menu of these "children of the air," we should, I submit, be very much surprised as to the composition of the bill of fare and the amount consumed.

We have to confess that thrushes and blackbrids have given us anxious moments this year, and we have caught more than one entangled under the netting; but even when we had our prisoners safe we could not find in our heart to do any other than let the frightened birds go, as we count them among the most gifted of our singers. There is no bird, perhaps, more faithful than the thrush, and surely he is the chiefest of musicians. Maybe these lines will catch the eye of someone in a distant land, who conjures up thoughts of home, and with it the garden that he loves and the minstrel that kept company, on the topmost bough of trees in the orchard! What would his views be now as to our lovely songsters? Would he not think that the good they do far outweighs the harm? Would he not be inclined to say:

The cherries that they eat
Are not so sweet
As are the songs, these uninvited guests,
Sing at their feasts, with comfortable breasts"?

We think so.—W. LINDERS LEA.

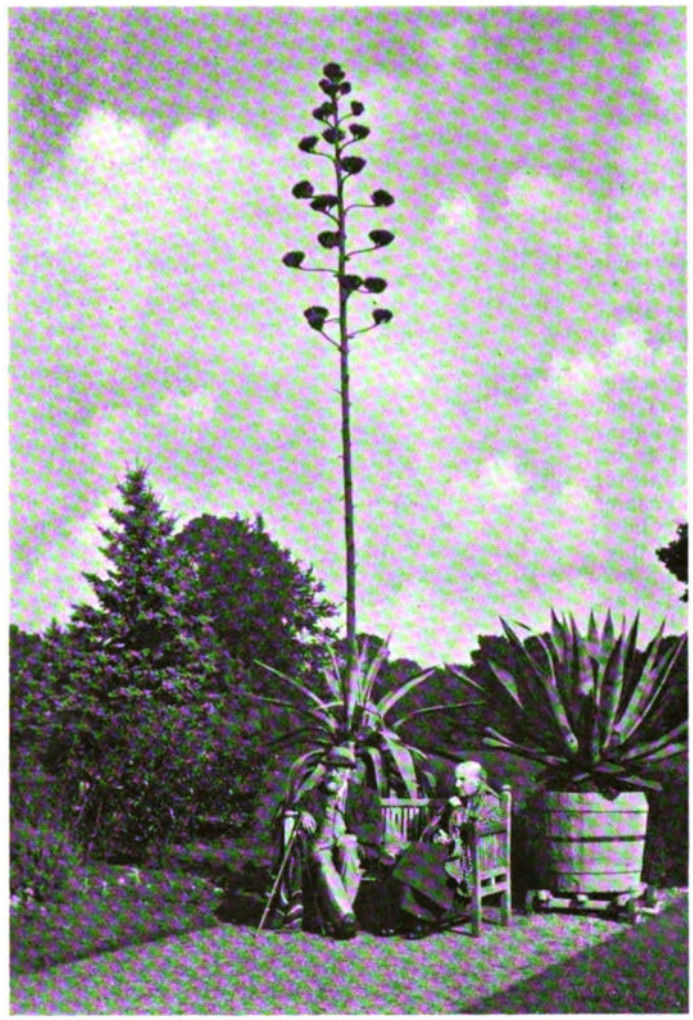
LILIUM AURATUM.

SIR,—In your issue of THE GARDEN, November 1st, page 752, under the heading "Lilium auratum," G. Dell Clarke, Bournemouth, draws attention to the photograph of L. auratum grown by him out of doors and represents what he thinks is a record, with twenty-seven flowers on one stem. I have a Lilium auratum, grown in an 8in. pot, with two flower spikes, one spike with forty-two, the other with forty-four flowers, eighty-six altogether. This is only one out of a batch of two dozen bulbs grown in pots, the smallest having a flower spike of forty-eight flowers.—G. S. LONDON, *Forfarshire*.

A FLOWERING ALOE.

SIR,—The enclosed photograph may be of interest to your readers. It is one of two aloes that were brought by a friend from Madeira in the year 1851. They have never shown any sign of blossoming during the seventy-three years that have elapsed since, until this year when one of them has rather suddenly thrown up this spike of bloom. It measures 19ft. in height from the top of the tub in which it is grown. You will notice how much the leaves of the plant that is in flower have shrivelled up as compared with its fellow plant. When the bud first appeared there was no difference between them in this respect. I fear this means that the plant will die when it has done flowering, as is generally supposed to be the case. Can you or any of your readers tell me if there is any way to prevent this? It seems a pity to lose a plant that has been so long in the family.—WILLIAM S. CLARK, *Somerset*.



A MAGNIFICENT ALOE SEVENTY-THREE YEARS OLD.

CATALOGUE DESCRIPTIONS.

SIR,—In my opinion, the omission to give the height of the plants is one of the most annoying, as well as the commonest, defects in nurserymen's catalogues. In that issued by a leading grower of herbaceous plants the height of only one or two in every hundred is given; consequently, I find it necessary to "work" the catalogue with the aid of half a dozen books on horticulture, which is a great nuisance. I agree, too, with your correspondent, Mr. Humphrey Swann, that to describe a thing simply as "dwarf" is absolutely useless; why should not the maximum height be given? It would be a great advantage, also, if all catalogues were arranged *strictly* alphabetically. This plan would save an infinite amount of trouble in searching for a plant.—R. E. H.

MAGENTA AND COLOUR COMBINATIONS.

SIR,—On returning home after a somewhat prolonged absence it was most interesting to pick up THE GARDEN once more and to find that the subject of colour combination and the right placing of magenta were still to the fore. In April and May, 1923, I pointed out that Cheiranthus Allionii appears to have been sent to restore to us the balance which the magenta of the aubrietia so vigorously disturbs. It was mentioned, also, that although Lunaria biennis is excluded from some gardens, the use of honesty is the best policy, when it can be associated with the rich brown wallflower—a colour combination which we find on the wings of the peacock butterfly.

"Colour mixtures are certainly popular with artists," as your correspondent, writing from St. Briac, in your issue of September 27th states, but he treats us to some of the most irritating examples that it is possible to find. The first selection he gives consists of marigolds, polyanthus, in what he terms "shades" of red, yellow and blue, mauve single stocks, pansies, woodruff and Virginian stock. In this country, marigolds are not easy to obtain in flower at the same time as polyanthus. The strong true orange of the marigold gives a dominating colour note that kills that of the weaker yellow primrose, and which, to use a musical phrase, is a tone above. The red, that he advocates the use of, is a tone below. This has precisely the same effect on the eye as three consecutive musical tones have on the ear when sounded together. To this horrible discord your correspondent adds blue, the mauve of the single stock and pansies. The colour of the single stock is about as raw as it is possible to find, which requires a strong complementary colour to render it tolerable, yet he places it with pansies (presumably purple) and blue—both semitones! Virginia stock is not a pleasing colour. It is what your other correspondent, "H. P. M.," would, I think, curiously term a blue-pink. Few would consider it worthy of a place in any decorative scheme, though it may still be found in some cottage gardens. Later in the summer, your correspondent suggests, a combination of love-in-a-mist with annual larkspurs. Here again, *blue* larkspurs must be rigidly excluded as they are on the violet side of the true blue and therefore form a discord with the Nigella. White larkspurs and pale pink ones might be used with Nigella, but pale lemon yellow such as the carnation would be better. The use of snapdragons and sweet williams is suggested, but no colours are mentioned. Their habits of growth and colourings are remote from the nigella and delphinium.

The combination suggested for the autumn is golden rod, rudbeckia, montbretia and the brown seed-spikes of the stock. I am not familiar with the last-named, but if the montbretia be an orange one, it is about a tone below the colour of the golden rod, and far better used by itself. Should a colour mixture be required, rich warm purple Michaelmas daisies provide the complementary tone; but *one* of the two colours should act as the *principal*, and dominate the whole of the decoration in the room or on the table, as advocated in your article on page 594.

When combining colours, it is useful to remember that the sensation of extreme violet, at one end of the spectrum, is caused by vibrations having double the frequency of those which give the sensation of red. These two colours roughly give us the first and closing notes of the octave. We find them combined in one flower in the fuchsia and Tulip Gesneriana spathulata. The colouring of the Babiana rubrocyanea may be likened to the musical "diminished seventh." Just as the musical intervals known as the third and the fifth produce a pleasing chord, the like intervals produce one in the colour scale. In each case the vibrations causing the sensation follow one another with a sufficient interval of time between them to prevent interference. If the interval is short, the vibrations clash with each other, and before the effect of the first on the retina is exhausted it receives another impulse, thus producing physical fatigue and a sense of great irritation and discomfort.

The complementary colours are any two which when combined give the sensation of white light. When seeing one of these the eye craves for the other, and the introduction of it in the garden or in an arrangement of cut flowers is always safe and pleasing. It is much to be hoped that the days of the barbaric jazz and Futurist horrors, and the indiscriminate mixing of various tints without reference to the laws of colour harmony, are now numbered, and that we may speedily be relieved of what is a nightmare to many of us—H. H. WARNER, *East Herts*.

FORTHCOMING EVENTS.

December 2.—Royal Horticultural Society's Fortnightly Meeting.

December 3.—Glasgow and West of Scotland Horticultural Society's Meeting.

December 6.—Blackburn Horticultural Society's Meeting.

December 8.—United Horticultural Benevolent and Provident Society's Meeting.

SIMPLE GARDENING

THE TREATMENT OF BULBS WHEN TAKEN FROM THE ASHES.

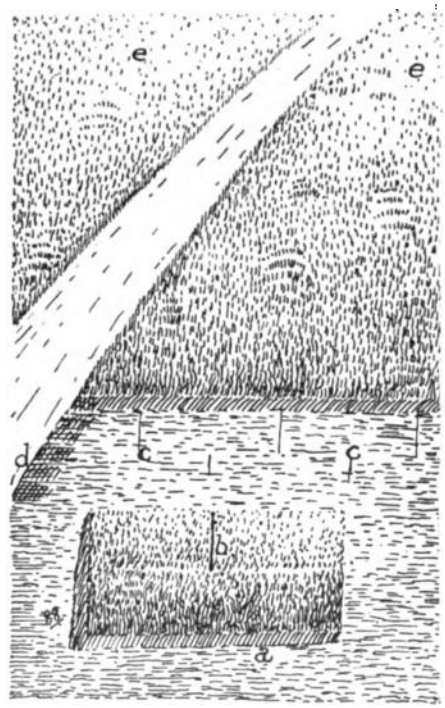
THERE are three very interesting stages in the care of bulbs grown in pots which always appeal to me very strongly, namely, the first handling of them when they are potted, when taken from the covering of ashes or sand and when engaged in arranging the plants on the stages and in bowls when the flowers are developing. I daresay all lovers of bulbs feel similarly. Nearly all the ordinary bulbs, such as those of hyacinths, tulips and narcissi, are buried under ashes, soil or sand after they are potted and, generally, kept in the open air. Empty inverted flower-pots placed in position to keep the covering material from interfering with the new growths are to be preferred to the placing of ashes directly on the pots. About one month after the potting has been done the cultivator should carefully examine the buried pots, and if the new growths of hyacinths and tulips are a little more than 1in. high the pots should be removed to a cold frame. Narcissi should have growths quite 2ins. high before they are taken to the frame. The latter should be ventilated a little at the top but kept darkened by placing mats on the glass for one week. Then gradually expose the bulbs to the light, admit more air and only protect from frosts. Take a few plants at a time to the greenhouse or conservatory to ensure a regular display of flowers. The best way to feed the plants is by standing the pots in saucers of liquid manure for a few hours weekly as the flower-buds form.

PREPARING GROUND FOR ANNUALS.

To some readers it may seem premature seriously to think of preparing the soil for annuals to be grown next year. But it is not a bit too soon. Many cultivators know, through sad experience, how disease and insect pests will work havoc among the plants in some parts of the country. When the young plants are growing in their flowering quarters it is too late to apply any drastic remedies. But lime and soil fumigants may be used while the ground is vacant, and thus destroy pests, their eggs, etc., and the spores and mycelium of fungi. To a limited extent these measures may be taken where the positions for the annuals are near the front of a herbaceous or similar border. Where it is convenient the borders for the annuals should be selected now and the soil deeply dug. There are several common mistakes made by cultivators every year, and it is mainly through these errors that unsatisfactory displays of flowers result—lack of manure, deep digging and timely thinning out of the seedlings. The deep digging should be done now, the top spit being turned over on subsoil that has been well loosened with the garden fork to a depth of at least 2oins. Then the lime should be applied to the newly dug surface at the rate of 6oz. per square yard of ground. The ground should be left in this condition throughout the winter.

LAYING DOWN NEW TURVES.

There will be many thousands of new turves laid down in readers' gardens during the coming winter months. Some lovers of nice lawns will be fortunate in securing good turves, others less fortunate, but all should lay the turves as carefully as possible. The best turves are those cut from old pastures or downs where fibre is abundant and weeds scarce. The 3ft. long turves are generally sought for. I, personally, like those cut 1ft. square or 1ft. by 1oins. The small turves are easily placed in a wooden frame 2½ins. deep, turned over grass side downwards, the soil part pared off quite level and the roots of coarse weeds removed. The soil should be neatly levelled after careful preparation.



The joining of two turves should be opposite the centre of another as shown at *a* and *b* and *c*, *c*. Near the border or path the soil must be freed from stones and made very firm, shown at *d*; then the edge remains level and stones do not interfere with the annual edging and cutting. The finished lawn is shown at *e*, *e*. Fine, sifted, heavy loam is useful for filling up openings between turves. Heavy planks are useful for beating down the lawn at first.

PROPAGATING WINTER-FLOWERING CARNATIONS.

A few years ago amateur cultivators were content to begin the propagation of slips early in March, but they are, rightly, not content to do so now. The first flowers were not available from the March propagation early in the following autumn. But from December and January propagation blooms were open for the October and November shows, and the plants continued to bloom throughout the winter, producing a rich harvest in the spring. As with chrysanthemums so it is in the case of carnations strong artificial manure is neither necessary nor desirable. But I would use the heating apparatus where such is available to prevent the temperature falling below 35° in bad weather. There are two ways to propagate, namely, in boxes and in tiny pots. Where convenient use the pots, as there is no check to progress when the cuttings are rooted and moved from one receptacle to another. First, with regard to the boxes. These should be about 1oins. deep, any size, and covered with loose squares of glass in the absence of a propagating frame. First, again, place a thin layer of half-rotted tree leaves in the box or frame, then a layer of washed and dried sand. The best cuttings are those taken from midway up the stem; the base of each cutting should be slit upwards half an inch. Insert them 2ins. apart each way, water and close the frame. The glass should be dried twice daily. Unlike the chrysanthemums, a rather dry state of the sand proves harmful to carnations. When the cuttings are rooted the leaf-soil adheres to the roots and prevents a check when first potted.

FORCING STRAWBERRIES.

The first ripe strawberries are always highly appreciated. The owner of a greenhouse may have these ripe fruits at an early date if the plants are treated in the right way. It is right to start the new growth very gently and wrong to subject the plants to a strong heat at the first. Frost will not harm the crowns of the plants, but it will, when the thaw comes, crack the pots. If there is a heap of tree leaves available, they should be used to pack between the pots; others, a little later on, should be formed into a mild hotbed either in the open air or in a frame; for preference, in the latter. Plunge the first batch of strawberry plants in this hot-bed, burying the pots to their rims. In this bed allow the plants to remain about twenty days; the gentle heat will induce early root-action and this means strong growth from the crowns when the plants are placed in the greenhouse. Watering is not necessary, as there is sufficient moisture arising from the leaves at first. Before the plants are taken to the house place the pots on the surface of the leaf-bed for three or four days to avoid a big check to the roots. A shelf about 3ft. from the roof glass is a good one for the plants, but cold draughts should be guarded against. Water judiciously, never allow the soil to get very dry; turn the flower trusses to the sunny side of the shelf when sufficiently grown, syringe in fine weather to keep down red spider and feed with liquid manure when the fruits are formed. Bring on the plants in small batches.

GEORGE GARNER.

BOOK REVIEWS

THE gardens of Europe, and of more recent date, those of the New World have formed the subject of several exhaustive treatises dealing in general with the cultivation of plants both indigenous and exotic in that particular part of the world, but those of South Africa, unless treated from a more scientific standpoint, have been comparatively little known or noticed until the present time, when an interesting volume in the shape of "The Gardens of South Africa," by Dorothea Fairbridge (A. and C. Black, Limited, 4, 5 and 6, Soho Square, London, W.1, price 10s. 6d.), has come to our hands. South African plants in past years were little known in this country, and it is only recently with the added stimulus of an excellent exhibit of native plants at the South African building at Wembley that the beauty and value of the indigenous flora of that great Union have been recognised. The book in question should do much to further and foster this newly awakened interest in plant wealth in these southern lands, as graphic descriptions are given of a few of the gardens existing in the Cape, Natal and the Transvaal, in addition to several useful chapters dealing with the native flora and its cultivation, which the beginner will find extremely serviceable in overcoming all the intricacies and pitfalls which beset his path. The volume is full of useful suggestions and hints, many the outcome of personal experience, and they are clearly set forth in simple language which will be readily understood by all. Lists of useful plants and a short monthly gardening calendar should be of great assistance to all those engaged in the pleasant pastime of gardening south of the Equator. The fore part of the book is more in the form of a story, treating lucidly yet instructively of the history of the rise of gardening in that country with the advent of the Dutch East India Company. It is to the pioneers of that Company that South Africa owes much of her exotic flora, especially those plants from the East which so brighten their gardens at the present day.

Numerous coloured illustrations appear throughout the book, and to our English eyes these may seem overdrawn, but very probably give a fairly accurate representation of the wealth of colour which is to be met with in these sunny climes.

The author has a graphic and easy style, indicating a thorough knowledge of her subject, although in parts the matter is somewhat sketchy, and it is a book which we should recommend to our readers in South Africa and to those in this country who devote any of their energies and time to the culture of South African plants. G. C. T.

IN these days of the great popularity of all sports, notably tennis and golf, and with the enormous amount of literature which is already devoted to these games and how to play them, it seems passing strange that no further practical manual has been compiled to aid the general public in carrying out an scheme of lawn making on their own account and also to teach and assist those who are already initiated into the art of greens and how to maintain them save that of "Lawns, Links and Sportsfields," by James Macdonald. That longfelt want (and how long it is we are in a position to judge by the numerous letters we receive from readers asking for advice in the remaking, etc., of a lawn), however, has now been filled by the excellent manual, "Lawns for Sports," by Reginald Beale (Simpkin, Marshall, Hamilton, Kent and Co., Limited, London, E.C.4, price 12s. 6d. net), which enters more fully into the subject than the aforementioned publication. Mr. Beale is well qualified to write such a book and give advice on all matters relating to general lawn management and the reader will not be disappointed, as the book is full of good, sound, practical advice, taken out of a vast store of knowledge gained from a personal experience over a considerable number of years as the manager of the Golf and Sports Department of Messrs. James Carter and Co. To all who are interested in the lawn, its formation and management and the general upkeep of golf courses, tennis courts, bowling greens and other sports grounds, the manual will prove invaluable. The advice is set forth in a clear and concise manner and in the simplest style. Although the title of the manual, is "Lawns for Sports," to the amateur, many chapters will be of the utmost service, such as producing turf from seed; turfing; weeds, a most necessary chapter, adequately treated; fertilisers and quantities to use, and purposes for which they should be employed; methods of dealing with pests, such as worms; drainage; and those four excellent chapters on mowing, rolling and the machines necessary, together with descriptions and prices. In short, it is a perfect practical treatise on the lawn in an exceedingly handy form and is one which we recommend to all our readers in the interests of beauty and economy in the upkeep of the lawn.

"Gardening in Sunny Lands," by Mrs. Philip Martineau. (Richard Cobden-Sanderson, 17, Thavies Inn, London; price 15s. net.) A book of great practical interest dealing with gardening in its many aspects in relation to the climatic conditions found in the Riviera, California and Australia. It is charmingly written by one who is an authority on the subject.

"The Four Gardens," by Handasyde. (G. T. Foulis and Co., Limited, 91, Great Russell Street, London.) The story of four gardens—the haunted, the old-fashioned, the poor man's and the rich man's. It is excellently written in a most natural style. The pictures drawn in the little book are very realistic and somewhat quaint and amusing. It is beautifully printed and the colour illustrations are good. It is a little book which any lover of the garden will enjoy.

BOURNEMOUTH HORTICULTURAL SOCIETY.

THE annual autumn exhibition was arranged to be held in the last week in October, but on account of the General Election taking place then, it was postponed to November 12th and 13th, and almost in every way it proved a success. The number of entries was large and competition keen.

In the open division, Mr. A. E. Usher, gardener to Sir R. Baker, Bt., Blandford, won three silver challenge cups for a display of chrysanthemums, six vases of blooms and four vases, respectively. He was also successful in the classes for collections of vegetables; collection of six distinct kinds of fruit, twelve dishes of apples and two bunches of black grapes. Mr. Lewis Smith, gardener to Captain M. Drummond, Cadland, Southampton, was also very successful in the classes for single dishes of apples. Mr. W. Weaver, gardener to Lieutenant-Colonel Tinker, Chewton Glen, Highcliffe, won the challenge cup for a collection of twelve distinct kinds of vegetables, and for three begonias in small pots. Mr. G. Garner, Delamere Lodge, Highcliffe, was first in the class for a decorated table of fruits, flowers and vegetables in keen competition. He won the silver challenge cup for fifteen chrysanthemum blooms on long stems in vases, staging Mrs. G. Drabble, W. Rigby and Mrs. J. Gibson, large and very fresh. The N.C.S. certificate of merit was also awarded to these blooms. He also won in the classes for nine blooms, for black grapes and salads. Captain Stebbing, Mr. E. J. Wilkins and Dr. Ramsay of Bournemouth were prominent prize winners in the single dish classes for apples and pears. Mr. R. Shave, Wilkford, Christchurch, won two silver challenge cups in the amateurs' division for a collection of vegetables and "points," respectively.

NON-COMPETITIVE EXHIBITS.

Large Gold Medal.—Messrs. Stuart Low and Co., Enfield (orchids and carnations).

Small Gold Medals.—Leonards, Bournemouth (floral designs), Toogood and Sons, Southampton (vegetables and chrysanthemums), Butler Bros., Bournemouth (floral designs).

Silver Medals.—Skelton and Kirby, Pirbright (rock plants and shrubs), Stacey and Staddon, Bournemouth (rockery), Hillier and Sons, Winchester (hardy shrubs), Grainger and Co., Bournemouth (bulbs and plants), Jeans and Trowbridge, Bournemouth (hardy shrubs), Ingram and Son, Parkstone (chrysanthemums and lilies).

Bronze Medals.—Messrs. G. Watts and Sons, Bournemouth (chrysanthemums), H. T. Sessons, Parkstone (roses), J. J. Kettle, Corfe Mullen (violets).

In Messrs. Stuart Low's collection, charmingly arranged, there were splendidly grown carnations and orchids which made a fine display. G. G.

LIST OF FRUITS SUITABLE FOR YORKSHIRE.

Apples, Cooking.—Early Victoria, Potts' Seedling, Cellini, Lord Derby, Lane's Prince Albert and Bramley's Seedling.

Apples, Dessert.—Worcester Pearmain, Jas. Grieve, Allington Pippin, Cox's Orange Pippin (in warm districts only), Chas. Ross and Newton Wonder.

Pears, Cooking.—Catillac.

Pears, Dessert.—Hessle (for standards), Fondante d'Automne, Fertility (for pollen-bearing), Pitmaston Duchess, Emile d'Heyst and Doyenne du Cornice.

Damsons.—Merryweather.

Plums, Cooking.—Early Prolific, Czar, Monarch and Victoria.

Plums, Dessert.—Early Transparent Gage, Kirke's and Coe's Golden Drop.

Red Currants.—Red La Versailles, Red Dutch and Comet.

White Currants.—White La Versailles and White Dutch.

Black Currants.—Seabrook's Black and Boskoop Giant.

Gooseberries.—Whinham's Industry, Red Warrington, Crown Bob, Green Ocean and Whitesmith.

Raspberries.—Pyne's Royal, The Devon and Balmforth's Seedling.

CATALOGUES RECEIVED.

Messrs. Morse Brothers, Melton, Woodbridge, Suffolk.—Roses.

The Four Oaks Spraying Machine Co., Sutton Coldfield, Birmingham.—Spraying and Lime-Washing Machines.

Messrs. James Vert and Sons, Saffron Walden, Essex.—Hollyhocks in all Varieties and Shades.

ANSWER TO CORRESPONDENT

Plants for Australia.—(E. M. C.)—The most suitable case for your requirements is a Wardian Case, if it can be obtained. It is the ideal way to send growing plants long distances. Bottom should be filled with fibre and the roots of the plants rammed in as hard as possible to keep them from shifting. Ventilation is supplied by two holes at the top of the case. A batten should be nailed down between each row on top of the fibre.

NOTES FROM CONTRIBUTORS

NANDINA DOMESTICA.

IN several parts of Gloucestershire this plant has proved hardy for a number of years, and this fact should encourage others in more favoured localities to try it. There was a beautiful plant in the garden of the late Canon Ellacombe's, Bitton, Gloucestershire, and Miss Jekyll in her book, "Wood and Garden," states that it struck her as one of the most beautiful growing things she had ever seen, the beauty being mostly in the form and colouring of the leaves. A short time ago it was in flower. Individually they are small and white with yellow anthers, but the glory of the plant is its brightly coloured foliage. In the full blaze of the sun it is almost scarlet, especially the younger leaves, which are well displayed on bamboo-like stems. N. domestica is often grown as a greenhouse plant, but in a pot its full beauty is never seen, and where any starved specimens still linger in the corner of a greenhouse just plant them out in a sheltered spot of the garden. It is a native of China and Japan, from whence it was introduced in 1804. In China it is known as the sacred bamboo, but it really belongs to the Natural Order Berberidaceæ. This plant is one that ought not to be planted in great quantity in every part of the country, but it will be quite safe in many counties.—T. W. B.

POLYGONUM POLYSTACHYUM.

MANY of the knotweeds are quite unsuited for the garden and must perforce find their way to the outlying portions of the grounds, the wild garden, and by streams and lakes, where there is ample room for their free development and where their beauty may be seen and enjoyed.

The above Himalayan plant, however, is an exception to this rule and may with advantage be introduced into borders containing other hardy flowers, as, unlike many of this family, it is easily kept within bounds.

Growing about 4ft. in height, this charming plant commences to bloom early in September, when large loose plume-like sprays of pale pink and white flowers appear in profusion, having the scent of honey and retaining their beauty over many weeks. Groups of it look remarkably well in the foreground of trees and shrubs, especially in full sunshine, and even when not in bloom are attractive by reason of their red-veined, olive green leaves.—E. MARKHAM.

TRAINED FRUIT TREES FOR SMALL GARDENS.

IT is a comparatively easy matter to arrange the space to be allotted to flowers and vegetables in a garden. When it is desired to have a supply of home-grown fruit in addition, it is a matter of consideration how best to use the space available, which is often more or less limited. Trees and bushes in the form in which they are planted in orchards are not always the best suited for garden planting. It is possible to obtain a supply of fruit with very little loss of space. In the case of apples, pears and plums, the trees will need to be in the form of espaliers or cordons, and in order that as little space as possible may be used, they should be planted as path or lawn borders. Bush fruits also may be grown in the two forms suggested for apples and pears, and although care and time will be necessary to train them to these forms, a considerable amount of space will be saved if this system is adopted. Bush fruits may also be trained as standards, and currants and gooseberries so trained possess a big advantage as regards space saving over the more general form in which they are grown. If planted between strawberry rows or other ground crops, they will take up no extra land, but if grown as bushes and planted in the same position it will be found that after a year or two one or more rows of strawberries will have to be dug up to make room for the spreading bushes.

Bushes grown as standards will need staking, but apart from this they are no more trouble than those grown in the more general form, and the fruit is certainly much more easily picked when it is on branches 4ft. from the ground than when it is necessary to stoop the whole time that the fruit is being gathered. Just as roses are budded on to briars, so it is often the practice to bud a drooping variety of gooseberry on to an upright variety, the result being somewhat similar to the umbrella rose. This method has certain advantages, but it is not as useful where space is valuable as is the simpler method of training cuttings of upright-growing varietise to the standard form.

Gooseberry and currant cuttings to be trained as standards are prepared in the usual way, with the exception that they may be much longer than cuttings intended to be grown to the bush form. When they have become well rooted they should be encouraged to make growth upwards until they have reached the desired height. The upward-growing bud should then be nipped off to encourage the young trees to send branches outwards to form a head, Any branches beginning to grow from lower down the stem should always be stopped as soon as they start into growth.

Wall-trained fruits are also useful in small gardens, and trees trained in this manner occupy no extra space. Unfortunately, however, suitable walls are not always available to grow enough fruit for household purposes. It is in gardens in which little wall space is available that tree and bush fruits trained as suggested will be found to furnish a welcome addition to the fruit stores, with a minimum allowance of garden room —T. W. MORTON.

CEPHALARIA TARTARICA.

THE cephalarias are tall, scabiosa-like flowers of commanding stature, as a rule, and generally well adapted for the back or near the rear of the border. They have flowers of various shades of pale yellow, with the general appearance of the scabiouses, which are so well known, either in the form of the annual scabious or the popular S. caucasica and its varieties. The general habit is quite good with their ornamental foliage and their flowers, which are not held erect, but face one, thus adding to their effectiveness in a border. They are, generally, tall plants with sturdy stems and rarely require support unless in very exposed positions. Their only failing is a distinct tendency to run at the roots, but this is not too pronounced, and they are easily kept in bounds. The cephalarias are perfectly hardy and grow in ordinary soil. Most of the few species in cultivation are about 5ft. or more in height. Propagation is effected by division in spring or autumn or by seeds sown under glass in spring, in the ordinary way for hardy perennials. Of the moderate number of species known to botanists, only a few are in commerce; but none of the other cephalarias surpasses or even equals that known as C. tartarica. Many years ago I had an opportunity of studying a collection of these plants in a botanic garden—the only real collection I have ever seen grown for comparison, and among the numerous species none there equalled C tartarica, a plant of which I then acquired, through the courtesy of the Curator, and which I have not been without since that time. It was the boldest, the largest-flowered and the most effective of all, and I have had opportunities since that of seeing various cephalarias in nurseries and elsewhere.—S. ARNOTT.

WHAT WILL YOU BE LIKE AT FORTY?

The athlete who won his blue at twenty is often unrecognisable at forty, and if you enquire far enough you will generally find that his deterioration dates from the day he went into business and had "no more time for games."

Mr. Thomas Inch has a lot to say about this sort of man in his new book, "Inch on Fitness." Lack of fresh air and exercise, the strain and stress of city life, take a serious toll of every business man's health, no matter what an excellent physique he starts with; but Mr. Inch demonstrates how easily that perfect fitness, and that supple figure on which he prided himself in his younger days, can be retained or regained by means of a little common sense and ten minutes' scientific exercising daily.

It is a book you should certainly buy and read, for although you may feel that your fitness and your figure are fairly safe for the present . . . will they be safe at forty?

"INCH ON FITNESS" by Thomas Inch.

RHODODENDRON NOTES

I HAVE just returned from Scotland, where I have been examining the progress made by my rhododendrons. In practically every case the growth made this year has been above the normal; even such tricky doers as R. hæmalium, hæmatodes and dichroanthum have added 4–6ins. to their stature, which for the dry and rather unfavourable east coast is remarkable. I have a number of the neriiflorum-sanguineum-hæmatodes group, and the only member which refuses to move is R. citriniflorum. It is planted in precisely the same conditions as others of the series, but there it sulks and, I am afraid, will ultimately disappear. I have a gully which appears to be particularly suited for Alpine rhododendrons, and yet here are two inexplicable failures, one R. calostrotum, the other R. scintillans. They are both perfectly hardy and are flourishing in many parts of the country, and yet with me they are steadily declining. I have one firm rule and that is never to coddle a rhododendron. I have had a fair amount of experience with them and give them every chance. These two will have one more year's trial: if they do, well and good; if not, out they go to make room for something else.

There has rarely been such a promise of flower in some parts of the country as there is this autumn. In the south and west many plants have been deceived by the mildness of the autumn and have tried to break into flower. I have seen R. Thomsoni with half-expanded flowers within twenty miles of London. Luckily, I have escaped this premature forcing so far, and the plants appear to have gone to rest definitely for the winter. From Cornwall and the South I hear a very different tale. Apparently, in those favoured climates rhododendron buds have been bursting right and left, a bad lookout for the spring.

A curious fact, noted all over the country this year, is that rhododendrons are to a great extent losing all their old leaves, thus making the plant rather ragged and open in appearance. The reason for this phenomenon is still obscure, but a possible explanation seems to me to be that the growth this year has been exceptionally vigorous, so much so that the root system has been unable to supply the whole of the plant, with the consequent starvation of the weakest members, namely the old leaves. This possibly accounts for another strange fact, that rhododendrons apparently in the best of health will either die outright or will shed a limb or portion of the plant. The more luxuriant a rhododendron is, the more liable it is to this sudden loss: it is curious that starved or unhealthy rhododendrons will never die with the same suddenness. It has been pointed out to me that when a limb dies off it either consists of or is topped by a second growth, but whether the second growth is the cause of death or the effect of weakness is not known.

Some rhododendrons, particularly of the Fortunei series, are liable to swelling of the stem, with consequent bark-splitting and sometimes death. It will be noticed that the stem below the swelling is constricted and tight. Little is known of the circulation system of rhododendrons, but a possible reason for this swelling might be that in a plant of strong growth the circulation system in the main stem is not large enough to carry the return flow of sugar-filled sap. The cells above the constriction which store this sugar become congested, with consequent swelling and splitting of the bark. The only cure is to cut the bark longitudinally below the swelling, but this should be done in July or August.

It is as well to point out again the value of examining the ball of rhododendrons which have been lifted. If they come from a heavy soil and are planted in a light soil without having their roots freed of some of the clay or heavy loam, progress for some years will be slow. The roots are so clogged by the heavy soil that they have little chance of expansion. It must be remembered that clay will never mix with loam and that the clay will be found on the roots many years hence. This does not mean that the roots must be cleaned, because they are so fine that this is impossible without serious damage, but the ends can be freed to some extent and carefully teased out. This applies to all sorts and conditions of rhododendrons.

A correspondent has written to ask when is the best time to collect the seeds of rhododendrons. The capsules should always be left on the bush until they have begun to split at the apex. At home it is easy to wait for the exact moment, which is usually after heavy frost, but in the wilds it is often impossible to catch them at the right moment, and the capsules have to be gathered before they are completely ripe. They are then either allowed to open by exposure or are artifically ripened in front of the fire. This is a mistake and may account for the poor germination of an occasional packet of recently introduced seed. E. H. M. C.

AUTUMN COLOUR in the GARDEN

BY MARK FENWICK.

NOW that the autumn garden is over and most of the leaves have fallen, it is worth while looking back and making a note of those trees and shrubs which have given the best display of autumn colour this year.

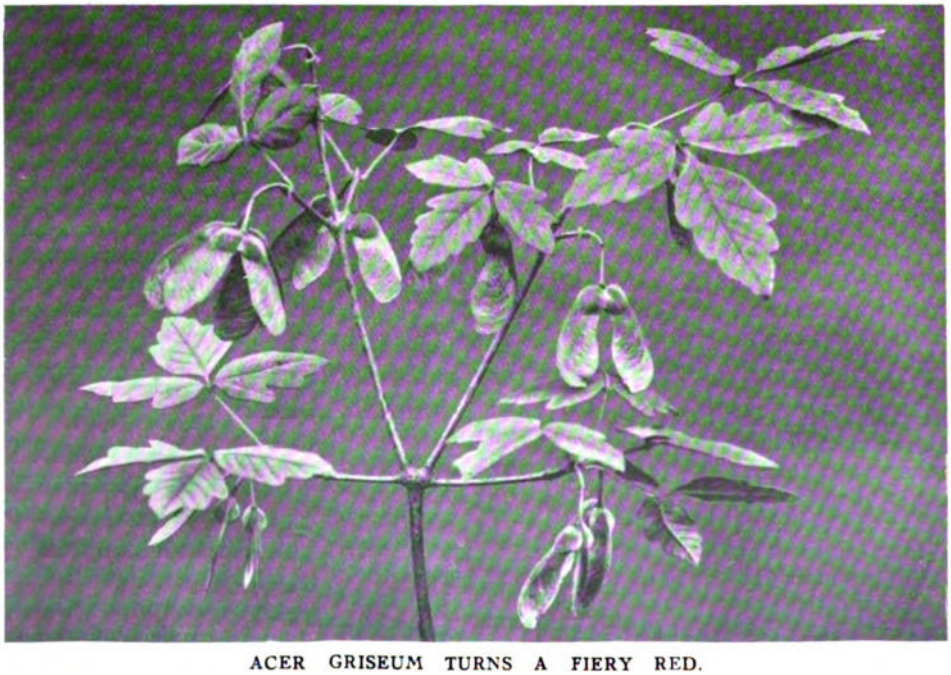
It may be said at once that, on the whole, it has been a good year, certainly much better than we had any right to expect after such a wretchedly cold and wet summer. It is nearly always the case that some shrubs fail to colour for some reason or another which no one seems quite to understand, and this year it has been the berberis family which have been very disappointing, even B. Thunbergii, which invariably turns scarlet here as early as the end of August or beginning of September, was quite poor. Almost the only one to colour was B. aggregata, though B. Polyantha is now making an eleventh hour attempt to do its duty, and is succeeding fairly well. BB. virescens, dictyophylla and yunnanense, which can generally be relied on to colour well, have been very poor, but on the other hand some of the family, such as Prattii, Wilsonæ and Stapfiana, have produced most magnificent crops of fruit.

Cercidiphyllum japonicum is always a first shrub to turn colour here and in my opinion is *facile princeps*, as no other shrub can produce such dazzling effects of crimson, scarlet, orange, pale yellow, pale pink, purple and green at the same time. This year it was extra good and lasted from the first week of September to the middle of October.

Acer tataricum Ginnala is always early and good, so is Nyssa aquatica, though the leaves of the latter fall all too soon. The Japanese maples were rather disappointing on the whole, although the palmatifidum divisum forms gave a brilliant pyrotechnic display for four or five days, and then shed every leaf, and the only other two varieties which have been good here were Polymorphum atropurpureum and one called by the Japanese name of Osakasuki. This is a magnificent variety with green and rather uninteresting leaves in the summer, but which never fail to turn the most brilliant scarlet in late autumn, generally about October 18th.

I think Vaccinium corymbosum, Enkianthus japonicus and Euonymus alatus were all extra good this year; the last-named turns a kind of Rose du Barri pink, quite distinct from any other coloured shrub in the garden and is certainly one of the very best; moreover, it has the advantage of holding its leaves longer than anything else and even now (November 15th), is still almost in full leaf and looks very well with pampas grass and Cotoneaster horizontalis against a background of yew and holly. Euonymus latifolius atropurpureus is also a most reliable autumn colourer. It becomes crimson about the beginning of September and retains its leaves till the middle of November. Of the Acers, dasycarpum and lætum are, as usual, good, but A. rubrum was only moderate. My plants of nikoense, griseum and rufinerve are too small to colour really well, but the variety rufinerve albo-limbatum turned a brilliant colour though only a small plant.

A RELIABLE AUTUMN COLOURER E. LATIFOLIUS ATROPURPUREUS.



ACER GRISEUM TURNS A FIERY RED.

When at Batsford Park a few weeks ago, I was lucky enough to catch at its very best a tree of Acer nikoense, which had been planted by the late Lord Redesdale about twenty-five years ago, and the shrimp-pink leaves seen against a blue sky made one of the most entrancing pictures I have ever seen. To return to my garden, Parrotia persica, so fine in some places with its scarlet and yellow leaves has never done itself justice here, but I have hopes of a young plant sent me two years ago by Sir George Holford from Westonbirt, which is growing in full sun and which made a gallant attempt to colour this year and may do better next.

Liquidambar has always been a failure here, but some of my trees were rather better than usual and are still holding their leaves, as are Quercus palustris and Q. marylandica and

Digitized by Google

Waterer's Scarlet Oak, though these all lost their brilliancy after 9 degrees of frost.

Rhus Cotinus has not coloured at all, but one of my purple-leaved forms has turned a very pretty red. R. cotinoides also failed, but R. typhina laciniata was brilliant, so was R. sinica, a little known but very pretty and graceful shrub which carries scarlet as well as green leaves at the same time.

Azalea Vaseyi was good and the common A. pontica better than I have ever seen it. Fothergilla major was almost the only shrub to turn a good clear yellow in early October, as the Gingko and tulip trees do not colour till later in the month; the latter, by the by, never turns a really good colour and is always rather rusty. F. monticola does not appear to be well known in gardens, it is of dwarf habit and its leaves turn red and yellow, and is altogether a desirable plant for lime-free soils.

Photinia villosa is quite one of the best colourers and is very largely used in conjunction with Amelanchier canadensis and Pyrus discolor for autumn effect at Sheffield Park where Mr. Soames has a splendid collection of autumn-colouring trees and shrubs. It was here I saw a beautifully coloured specimen of the rare Disanthus cercidifolius, which as far as I know is unobtainable anywhere, as I have tried all the English and the principal Continental nurserymen, and I am now trying Japan, of which country it is a native. There is a plant at Kew, but I believe it does not colour. A tree which had turned a fine, clear yellow at Sheffield Park was Davidia involucrata which I did not know was any good in autumn. My form of amelanchier which came here under the name of A. Botryapium has much larger leaves than the Sheffield Park tree, and they turn scarlet and orange.

Ribes aureum coloured well here, but R. americanum, of which Messrs. Cheal showed some finely coloured branches at one of the autumn shows, was quite a failure. Other shrubs which coloured well were Gaylussacia dumosa, Rhodora canadensis, Sorbaria arborea, Pyrus Sorbus japonicus, Stachyurus Willmottiæ, Pyrus arbutifolia, Aronia atropurpureum, Prunus pumila and P. Sargenti, Viburnum tomentosum Mariesii, V. plicatum and V. Opulus, Rosa nitida and R. lucida and Cratægus coccifera. C. prunifolia, though generally a fine colour, failed this year.

My cornus trees are only small but C. Kousa coloured quite well and CC. florida and Nuttallii a little.

The vines, except the claret vine (Vitis purpurea) were poor, Andromeda arborea (oxydendron), fair, and last, but not least, Eucryphia pinnatifida is now a glorious sheet of orange and scarlet. This about finishes my list (and high time, too, I think I hear the Editor say), but Stephanandra Tanakæ and Celastrus articulatus have still time to turn yellow if severe frost keeps away.

I am aware than many owners of good gardens take very little interest in autumn colour and say it presages the fall of the leaf and the approach of winter, but surely no one who has seen Westonbirt or Sheffield Park about the third week in October could fail to be struck by the lovely picture displayed there. For my part I get as much pleasure out of my October garden as from any month of the year, because the tints vary every day and one hardly knows what fresh picture the next day will bring forth, and if these pictures last till the second or third week in November, as they have this year, it must surely be worth while growing some of the shrubs I have enumerated.

VERONICAS

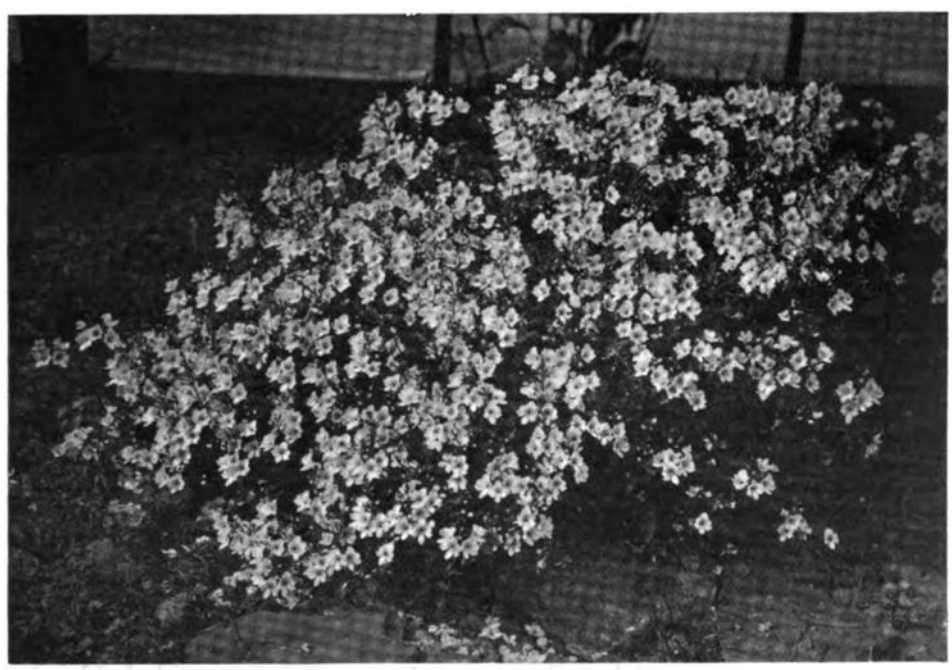
VERONICAS are among the most useful and most beautiful of flowering shrubs and plants. The genus veronica is an extensive one, consisting of over sixty varieties to my knowledge, and there is a good number with which I am not yet acquainted.

The various species differ considerably, from tiny gems for the rock garden to the handsome shrubby species which, according to their variety, are useful for greenhouse decoration, herbaceous borders, shrubberies, for planting in woodlands as single specimens in bush form or as standards. With such a huge and varied list for selection, there is no trouble to suit the requirements of the owner of a large or small garden.

Their value in gardens situated near the sea is well known, as they readily adapt themselves to the strong sea air and are not distressed by the rough winds. They are not particular regarding soil and seem to thrive in anything from sand to chalk.

In exposed districts some of the shrubby species are not quite hardy, but in the South and West of England they need practically no protection. Sometimes a very severe spell of cold weather will kill the existing growth, but the plants will come away freely in the following spring.

The propagation of veronicas is quite simple. The herbaceous varieties can easily be divided and replanted; this should be done in early autumn. Cuttings are the best means of increasing the shrubby varieties. These should be made from the young growth in September or October and rooted in a cold frame. Afterwards they should be potted into 3in. pots and grown on and kept as hardy as possible with covering at hand to protect them in very severe weather. It is best to keep the plants in pots through the winter and plant them out in the spring; they will then get well established before the next winter. This treatment only applies to the shrubby varieties, which are rather tender in the young state.



ONE OF THE SUBSHRUBBY SPECIES, VERONICA LYALLII, WITH PALE MAUVE FLOWERS.

In the following list I have selected some of the best varieties worth growing and a brief description of each. The majority of veronicas flower from June till August, and some varieties, according to atmospheric conditions, will continue to flower well into November.

VERONICA ALLIONII.—A rare species for the rock garden with flower-spikes of sapphire blue; 3 ins. high.

V. AMARANTH.—This is a handsome plant of the hybrid shrubby variety with fine crimson spikes of flowers. A good plant for the herbaceous or shrubbery border or as a specimen trained as a standard.

V. AUTUMN GLORY.—One of the finest shrubby veronicas for free flowering; produces small spikes of blue flowers which continue to appear from summer till late autumn. A fine plant for

Digitized by Google

massing on a large rockery; height about 2ft.

V. ANDERSONI.—Another shrubby variety with blue flowers which are paler toward the base of the spike.

V. ANDERSONI VARIEGATA.—A variegated form of the above—fine for greenhouse decoration—makes a fine standard.

V. BALFOURIANA.—Fine for the rockery; only 3ins. high with bright blue flowers.

V. BIDWILLII.—The true form is rare, quite a miniature of tiny leaves and white flowers. The false V. Bidwillii is a small sub-shrubby variety with white flowers. There is also a similar form called V. Bidwillii Lilacina.

V. BLUE GEM is a fine shrub growing 6ft. high with fine blue flowers. It is useful for making a hedge.

V. BUXIFOLIA.—The box-leaved veronica, very uniform in shape; extremely useful for bedding out. Produces white flowers, but not very freely. It is quite hardy.

V. COOKIANA.—A beautiful shrub with blue and white flowers on the same spike. It is very effective as a specimen; height from 3ft. to 4ft.

V. CUPRESSOIDES.—Resembles a dwarf cypress tree and gives off a smell like pencil cedar. It is rather rare, but very interesting, with purple flowers.

V. EDANTANTE.—A very free-flowering shrub with carmine flowers; height about 4ft.

V. GAUNTLETTE.—A grand shrub with flower-spikes of rich salmon pink, 6ins. long.

V. GENTIANOIDES.—A herbaceous variety; fine for the border, with spikes of pale blue flowers. Produced on stems 18ins. high. There is a variegated form,

V. GENTIANOIDES VARIEGATA, which makes an excellent border plant.

V. GUTHRIANA.—A small-leaved sub-shrubby variety, best grown with effect in the crevices of rocks or as a wall plant. Pale blue flowers.

V. HECTORI is quite a distinct variety; the foliage has a cord-like appearance. It looks very effective hanging over a rock; it is also quite hardy.

V. HULKEANA.—A gem for the cool greenhouse, where it will flower early in the year. The lilac flowers are borne on graceful stems which look very effective grouped with some graceful foliage, plants or ferns. It is also a fine addition to the alpine house. In some favoured districts it will thrive in the open, but it is not very reliable.

V. INCANA is very useful for the front of the herbaceous border or as a rock plant. The flower-spikes are of a very pleasing blue, produced from a mass of grey foliage. It is a very distinctive plant and much admired when in flower.

V. GLOIRE DE LORRAINE.—A shrubby species with lavender and white flowers on the same spike.

V. KOTSCHYANA.—A dwarf shrub with a loose, flopping habit with pink flowers;

THE STATELY SPIRES OF VERONICA VIRGINICA.

only 3ins. high. Excellent for the rockery.

V. LAVAUDIANA is a very rare shrub and very beautiful. The leaves are rather fleshy, with a red margin and short spikes of pink wax-like flowers. A grand addition for the rockery in a prominent position with shelter from the cold winds.

V. LONGIFOLIA is a herbaceous variety, very effective used in a stream garden with its upright spikes of blue flowers. It can also be used as a border plant, especially V. longifolia alba and rosea.

V. LYALLII.—A sub-shrubby species rather tender in most districts. A good plant for the alpine house. If grown in the open it is advisable to have plants in a cold frame through the winter in case those planted out are killed by the frost; they can then be replaced in the spring.

V. MME. DELEAUX.—A shrubby species with bright red flowers. Can be grown as a standard.

V. ORNAMENT is rather a distinct shrub with round leaves and pretty lavender flowers; about 2ft. high.

V. PECTINATA ROSEA.—A hardy variety for the rockery with grey woolly foliage and bright pink flowers. It makes an excellent wall plant.

V. PIMELIOIDES.—A dwarf shrub with purple flowers and glaucous foliage.

V. PINGUIFOLIA is very similar to the above in foliage, but it has white flowers and more erect growth. Both varieties are very ornamental as foliage plants in the rockery.

V. PURPLE QUEEN is a fine shrub for massing, as the large purple flower-spikes look very effective in a group.

V. REINE DE BLANCHE.—A white-flowering shrubby variety; very free flowering.

V. REPENS is a useful little plant for planting in paved walks or as a wall plant. It is very fast growing and smothers itself with white flowers, shaded with lilac.

V. ROTUNDIFOLIA forms a very thick bush, about 3ft. high, with fine blue flowers.

V. SALICIFOLIA.—The willow-leaved veronica makes a fine wall plant and is quite hardy as such. It is also valuable as a late-flowering shrub. It will flower well into November. The flowers are white with a blue tint.

V. SAXATILIS is not often seen in gardens, but it is a very pretty plant for the rockery, rather on the shrubby side, with a trailing habit, with rich blue flowers.

V. SPICATA, another herbaceous variety with blue flowers; very similar in growth to V. longifolia.

V. TRAVERSII is a handsome shrub with box-leaved foliage and pale lavender flowers. It forms a fine specimen plant and will grow anywhere, even under trees. It attains a height of 5ft. and is hardy.

V. VIRGINICA.—One of the tallest herbaceous varieties. It will with good treatment attain a height of 4ft. with bright blue flowers. An excellent plant for the border.

V. VEITCHIANA is a shrubby species with large handsome foliage and royal blue flowers; height 2ft. to 3ft. Rather late flowering; will make a good standard.

R. C. JOLLIFFE.

FASHIONS IN GARDENING

IT is difficult to speak of fashions without rousing some feeling of opposition, for the word calls up the idea of following passively, even unwillingly, someone else's lead. Yet it is really rather doubtful whether people accept the prevailing fashion quite as passively as they suppose. The fashion makers, who should know, insist that the public only accept what they really want, though they may not know what they want until they see it. This point of view, whether it be right or wrong, at least gives an interest to any striking change of fashion, and may even provide a self-satisfactory excuse for following it should one be needed. On the garden, more than elsewhere, it must be difficult to impose a fashion from without, for sooner or later the gardener's real preferences make themselves felt in that struggle for existence of which every garden is the theatre, and schemes which do not quite coincide with the owner's personal taste are gradually, perhaps unconsciously, modified. If we look at garden fashions from this angle it seems worth trying to discover the factors that lie behind the various changes of taste that occur from time to time. It will seem significant,

Digitized by Google

for example, that the rise of the informal, or natural, garden and the revolt against carpet bedding coincided with a growing tendency to admire the wilder kind of scenery, a tendency that was beginning to drive people farther and farther afield on their holidays, and it will be noticed that this coincided with the spread of urban conditions of life and with the drift of the population towards the towns.

With the informal garden came the rock garden, which soon acquired so strong an independent life and popularity that it may be taken as the most marked development of the general movement, just as the attraction of the high Alps is the most extreme reaction against the town. The rock garden, in its most austere form, has perhaps a special attraction for us because of its contrast with the lush exuberance of much of the English countryside. This contrast has led, quite reasonably, to adverse criticism of the rock garden as a thing inevitably incongruous with our landscape, yet the contrast seems to be part of its *raison d'être*, seeing that we naturally desire what we feel to be lacking in our surroundings. That this last motive counts for something seemed to be borne out by a little garden on a rock promontory in Dalmatia, where a keen gardener had removed at great expense a natural rock garden planted with cistus, Convolvulus Cneorum, Putoria Calabrica, Orchis pallens and other treasures of that coast in order to replace it with geometrical beds of geraniums and lobelia. And it seemed a very reasonable thing for him to do, seeing that he was surrounded by several hundred square miles of rock garden and he, naturally, wanted something different—as different as possible. His great desire, he said, was to possess a bed of sweet-scented violets, and the story of his solicitude and inevitable failure on that sun-baked rock would not have seemed strange to any gardener who had tried to reconcile, let us say, Calochortus or Oncocyclus iris with the English climate.

It is interesting to find in a late development of rock gardening that the almost hopeless attempt to bring the high alpines into harmony with the landscape has been frankly abandoned by growing them in stone sinks and troughs, so that each one with its square foot or so of alpine lawn or flowered scree becomes a tiny excerpt of mountain scenery rather than an imitation of it. This way of gardening, and the miniature rock gardens in general, may be looked upon as an attempt to bring the wild and natural element in gardening within the limitations of space and income that circumscribe so many gardens of the post-war period. These limitations may also account for the revived interest in the dwarf conifers, which had a short vogue about the middle of last century, and are now being used not only in the rock garden but also as specimen trees in the small grass plot and even for making a miniature pinetum. For the same reason dwarf shrubs, such as Osmanthus Delavayi, Cydonia Maulei, Buddleia Nanhœnsis, etc., are being more and more appreciated.

Perhaps the smallness of many modern gardens accounts for the return of certain old formal fashions, the knot garden and the paved and Dutch garden, since their full effect can be obtained in a small space; but there must be other reasons as well, for many of the old-fashioned florists' flowers have also returned to a popularity that is quite evidently independent.

To some people the old quilled daisies, flamed tulips and striped roses may not seem to come quite within the category of flowers, any more than do the tight little Victorian nosegays whose vogue immediately preceded them, yet many of us admit their charm, though, it may be, a little self-excusingly. Perhaps their artificiality and their association with the past suggest an aloofness from reality and its conflicts that may appeal to something in the mood of the times. These old florists' flowers (and we may add to the list the double primroses, gold-leaved polyanthus and double wallflowers) do not belong to the Victorian era, whose fashions, a little faded and sentimentalised, have lately re-emerged, for tropical flowers against a background of sombre shrubbery were more typical of Victorian gardening. They seem to belong rather to the time of Parkinson and his "Paradisus," a period, as one imagines it, of flamboyant vigour and individuality.

Most of our open admiration goes out nowadays to the single flowers, and especially to the wild species, with their balance of design and their perfect adaptation to the conditions that begot them, yet for all that an edging of double daisies and scallop shells has, somehow, a certain charm and fascination.

F. A. HAMPTON.

THE CHARM OF GARDENS

EVERYONE recognises the pleasures that arise from gardens. And not pleasures merely. Gardens give mental and physical relaxation. Away from the public gaze the garden yields a peace which is unknown amid the busy haunts of men. It is secluded, enclosed, fenced in. The word itself is suggestive of tranquillity and retirement, It is "a temple of Nature, where the goddess is enshrined, and where a devoted worshipper seeks to do her honour by delicately imagined devices." Nature cares not for novelty: she loves the old ways. She never assumes that she is not. Vulgarity is unknown to her. Disliking artificiality, she endeavours to remedy mistakes, and grows in her own wild and winsome ways. She frequently avenges herself on man's desire for the abnormal by not yielding her best, and though she has the power to adapt herself to her environment, the struggle is sometimes long and tedious. Foreign methods have from time to time influenced the character of our English gardens, but, generally speaking, the national traditions have been upheld, and though artificial developments form special features of the gardener's art, we still recognise the claims of "the old red daisies, the primroses, the polyanthuses, the simpler tulips and crown imperials that had their only homes in cottage gardens." Nowhere are beauty and utility so charmingly combined as in a cottage garden. Nine months out of the twelve you may have flowers, and some kind of edibles may be obtained during the greater part of the year. About such a garden there is nothing pretentious; there is no affectation. It is characterised by simplicity, which is the offspring of the highest taste and a prime element in pure beauty. There are no patterns; the form and colour are there, and both blend harmoniously, for Nature is a good colourist, and her sense of form is highly developed. Nor is fragrance wanting —"the fragrance of eternity," as Oliver Wendell Holmes puts it. The back garden may indeed be an avenue of regions transfigured by imagination to a veritable fairyland. Thus scent and form and colour gratify the senses; and, at times, when one would least expect it, there is a delightful pleasurable feeling as the gentle showers fall like "a patter of voices, quick, eager, multitudinous, full of hopes and projects."

In modern gardens we endeavour to obtain what Lord Bacon suggested in *his* day—"gardens for all the months of the year, in which, severally, things of beauty may be then in season." He enumerates the various plants that, in his opinion, should be cultivated in succession, and remarks: "thus, if you will, you may have the golden age again, and a Spring all the year long." And he proceeds to expatiate on "the breath of flowers," which, he says, "is far sweeter in the air than in the hand." He cares little for the ordinary rose, in which he finds "nothing of sweetness." He goes to the violet and musk rose to yield the finest perfume, and then enumerates a host of those old-fashioned flowers of the herbaceous type that, happily, are now prized for their simplicity and grace.

We do not care to follow him when he describes "the ordering of the ground," beyond this, that he divides his garden—be it remembered its size is some thirty acres —into three parts: "a green in the entrance; a heath and desert in the going forth; and the main garden in the midst," this "main garden" being the largest. His reason for this arrangement is obvious, his intention being to provide shelter alike in the heat of summer and a moderate temperature during the winter months.

We have come to recognise that a garden should have some affinity to the field whence it comes. It has gone through many transformations, but amid all changes it still possesses the homely flowers of past days. A garden is, indeed, "a filter to filter the grossness out of us." And may we not add that it reminds us of the Source of all life and teaches us patience and hope.

SOME INTERESTING PLANTS

HYBRID ARGEMONES.

TOO few gardeners know of argemones. Although several species exist that are well worth cultivating, including A. mexicana, deep yellow; ochroleuca, pale yellow; grandiflora, white; platyceras, white; platyceras rosea, reddish; etc., it is particularly the hybrid forms, a comparatively new strain, that are worthy of attention.

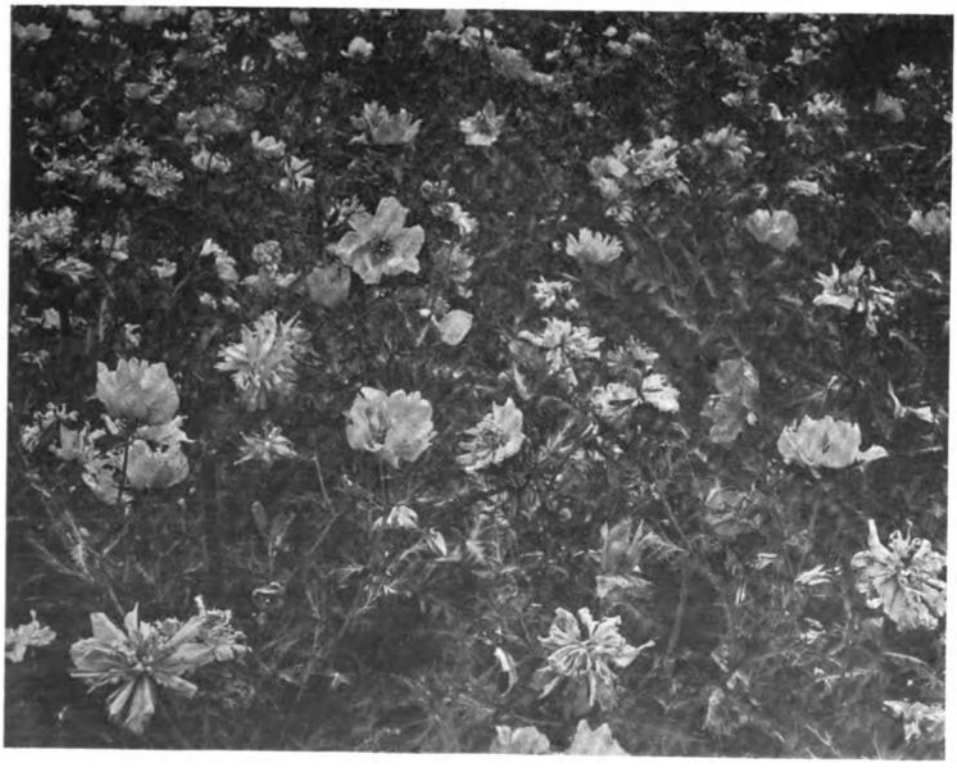
The origin of these hybrid argemones is curious. Twelve or fifteen years ago, while studying the laws of heredity for purely scientific purposes, Messrs. Vilmorin and Meunissier of Paris crossed the yellow single A. mexicana with the equally single, white A. platyceras. The first generation gave plants of a uniform yellowish tint. In the second came, besides whites and yellows and intermediate forms, a number of other shades and, what was most unexpected, several double flowers. In the generations that followed these double and differently coloured flowers, through selection, became more and more numerous, so that now strains exist that are perfectly double and range in colour from white and white shaded pink to pale yellow, deep yellow and yellow tinted red. All these plants are of striking beauty and, being of comparatively easy culture, are worthy of being grown in our gardens.

The argemones are members of the Papaveraceæ. They are perennial in warm countries but must be treated as annuals in our northern climate. Most of them are natives of tropical America. The best way to grow them in a warm garden is to sow them directly on the spot they are to occupy in deep, rich ground and very open situation, late in the season, that is, in May, when the soil has become warm. In cold gardens or in wet seasons it is better to sow them in pans or pots at the end of April in a house or frame and to transplant the seedlings, while very small, singly into small thumb pots. The transplanting in a very small stage is important, for the plants resent disturbing at the roots, and stand this best while in a very young condition. The young plants are then kept in a frame with plenty of sun and ventilation till big enough to plant in their permanent quarters. At that time it is very important again not to disturb the roots, a comparatively easy task with plants established in pots. Once the plants are fully established they do not give the least trouble and grow luxuriantly to a height of 2ft. to 2½ft., flowering abundantly from June till the frosts come. They should be planted 1ft. to 1½ft. apart. When the end of the season approaches the flowers of the double strains have a tendency to become single. The foliage of argemones is of a beautiful glaucous tint, but having the disadvantage of being prickly, the plant can be of little use for indoor decoration.

They are best kept, as a rule, on the dry side, especially in the young state, although during the hot season copious watering always benefits them.

Other beautiful hybrids of argemone have been obtained at times from crosses between other types; for instance, A. grandiflora × platyceras rosea, but unfortunately these have, so far, proved sterile. For the amateur who likes unusual plants another pretty plant to grow is A. platyceras rosea, already named, a dwarf kind with large, almost red flowers that is most effective through its unusual colouring. CHARLES LERAY.

A NOVELTY IN HYDRANGEAS, H. DOMOTOI.



HYBRID ARGEMONES ARE BEAUTIFUL ANNUALS.

A NEW HYDRANGEA

From Japan, through America, there comes a novelty in hydrangeas called H. Domotoi, which is likely to create a certain amount of interest. It is a double form (so it is claimed, at least) of Hydrangea Otaksa, which is said to have all the advantages of this species, in addition to doubling of the flowers, an interesting point that adds greatly to the duration of flowering and to the general showiness of the plant.

It was on the occasion of the Pan-American Exhibition in San Francisco in 1915, that the plant became known. A Japanese firm exhibited it there, where it was secured by a Japanese-American concern, the Domoto Brothers, of Oakland, California. The name of "Domotoi" was then given. In 1920, Dreer of Philadelphia, a most modern

Digitized by Google

establishment always on the look-out for any new and meritorious plants, got hold of some stock and began intense propagation at their Riverton nurseries. Of late, the plant has crossed the Atlantic, and several nurserymen, such as Lemoine of Nancy and Barbier of Orléans in France, are already listing it.

The new hydrangea, which the writer saw growing luxuriantly at Mr. Barbier's private garden at Orléans, is really a fine and interesting plant. It has the general appearance of H. Otaksa, but the flowers are of a fine pale pink and their double nature makes them quite conspicuous. This attractive doubling is, in reality, as is the case with Arabis albida flore pleno, only a proliferation of the external floral envelopes, although, in some cases, stamens are produced at the end of flowering, a peculiarity which is valuable for the hybridist and which never happens in arabis.

The plant is well adapted for pot culture, but it is rather as a hardy outside shrub that it is particularly valuable. In this last case, it stands the cold of the winter very well and is very free-flowering. All nurserymen who have handled it lay stress on this point.

Several hydrangeas with double flowers have already been offered to the public, such as H. stellata, H. s. rubra, etc., but these have never met with much attention. Hydrangea Domotoi, however, being far superior to these, will certainly soon make a place for itself in gardens, owing to its great decorative and other qualities. CHARLES LERAY.

THE CHINQUAPIN.

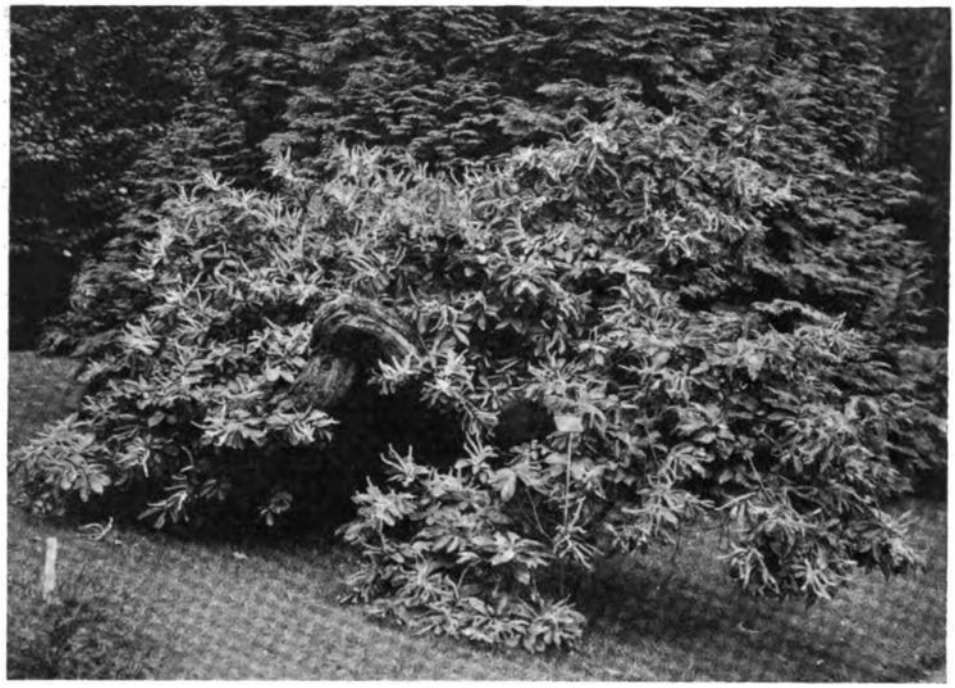
When, years ago, I visited for the first time the famous dendrological collection of M. Philippe de Vilmorin at Verrières, near Paris, I was surprised by the striking appearance of a fine flowering specimen of the North American dwarf chestnut or chinquapin, Castanea pumila, which is such a rare plant on the Continent and even in Great Britain. I was fortunate to get a picture of it which shows well the picturesque habit of an old plant. In its native country where it is found, according to Britton, from New Jersey to Indiana and southward to Florida, Missouri and Texas, it not infrequently becomes a small tree, attaining a maximum height of about 50ft. with a trunk diameter of about 3 ft. I have never seen a tree, for in our collections there are usually only small shrubs that do not grow too well. It likes a warm Continental climate to flower well and to develop its egg-shaped thin-shelled nuts, of which the seeds have a good flavour. The spiny fruit usually contains only one nut.

The firm leaves, which are rather light green and smooth above, are coated beneath with a fine rather persistent felt, and look almost evergreen. They are, however, deciduous, and form a pleasant background for the whitish male catkins appearing towards the end of May or during the first week of June. They form very graceful clusters, and make the plant unusually attractive. Through its habit of spreading by suckers the chinquapin often forms real thickets, and it ought to be planted more freely in warm situations there to become a conspicuous feature of our parks or large gardens.

We do not have too many plants of the habit of this dwarf chestnut. Most of our shrubs and smaller trees are rather stiff. Castanea pumila is of a different shape. Like its congeners it thrives without difficulty in any loamy and well drained soil. It seems to abhor limestone or, at least, too much lime in the soil, and it can be raised by seed or by suckers. CAMILLO SCHNEIDER.

THE BUTTONBUSH.

Among the rubiaceæ there are a great many fine flowering trees and shrubs, but very few of them can, even in England, be planted in the open air. On the Continent there is just one species that can really be regarded as hardy: the North American buttonbush, Cephalanthus occidentalis. Other plants of this family, like Serissa fœtida, Damnacanthus indicus and several species of coprosma from New Zealand, may be seen occasionally in



A FINE NORTH AMERICAN CHESTNUT, THE CHINQUAPIN.

A WARM GROWING PLACE IS NECESSARY FOR THE BUTTONBUSH.

Digitized by Google

small collections of rare plants—for instance, in the Botanic Garden at Darmstadt, Germany.

The buttonbush, however, is hardy in most parts of western and central Europe; but it is by no means a common garden plant. One of the finest pieces I met with was in the garden of the late Philippe de Vilmorin at Verrières. I took a picture of it years ago when it was in full bloom. It is a rather ornamental plant with its glossy green foliage and its uncommonly shaped yellowish-white flower-heads that appear late in August and usually last until almost the end of September. A well grown flowering bush is quite attractive.

In its native home the buttonbush grows in very wet or even swampy places. I collected it myself several times on the borders of swamps. On the Continent it thrives well in any good garden soil, and does not need any excessive water supply. I do not think it would be quite hardy with us in a really wet place. It seems to do best in a rather sandy but by no means dry soil, and in a warm sunny place where the wood ripens well. In such a situation it flowers very freely, but the seeds do not ripen in Central Europe, so far as my knowledge goes, except in very warm sheltered places.

After all, the buttonbush can be highly recommended as one of the more attractive late-flowering shrubs for small gardens as well as for the park.

CAMILLO SCHNEIDER.

CHRYSANTHEMUMS AT NORWICH

THE Norwich Chrysanthemum Show was held in St. Andrew's Hall on Thursday, Friday and Saturday, November 20th, 21st and 22nd. It proved to be one of the best in the records of the Norfolk and Norwich Horticultural Society, which goes back for nearly 100 years. The entries totalled 797. The exhibition chrysanthemums, both of the Japanese and single-flowered varieties, were staged in splendid condition. There were five entries in the class for thirty-six Japanese blooms, first place for these being secured by the Lowestoft Corporation (gardener, Mr. G. H. Smart). They also took premier position in the class for six vases three blooms with long stems in each. The premier positions for the singles were taken by Brig.-General Dale. There were three competitors in the circular group class of chrysanthemums and foliage plants in pots. Here Miss McLentock of Catton Grove took first place with a beautifully arranged group. Mrs. Barker-Hahlo of Langley Park, who was second, had perhaps better individual blooms on her plants, but the arrangement looked too heavy. Decorative hall vases and baskets were responsible for some very artistic displays Major Bruce was first for the vase with a combination of single pink chrysanthemums and golden privet foliage. Mr. Gordon Lang, Plumstead Hall, was first for a basket with light terra cotta flowers and beech foliage.

There was a goodly array of miscellaneous cut flowers, including some well grown carnations from Lord Ailwyn's gardens.

Of pot plants primulas made the largest show, but for a blaze of colour the salvias stood out pre-eminent, the best of these coming from Sir Edward Mann. Begonias of the Lorraine and the hybrid winter-flowering kinds were excellently shown by Mrs. Herbert Smith of Dealington Hall. Fruit was a very strong feature. It really did one good to see what splendid apples can be grown in the county of Norfolk. The nine dishes of distinct dessert kinds from the Earl of Stradbroke's garden staged by Mr. T. Simpson were ideal. This and the many other classes for dessert kinds were keenly contested. Of cooking apples one knows hardly how to express the magnificence of the exhibits, so superb were the huge quantity staged. The Rev. T. D. Chute, Moulton Rectory, who is quite an enthusiast upon apples, had the best nine dishes, clean and nicely finished; he also staged a dish of the new variety Monarch. The veteran William Allan, Gunton Park Gardens, surpassed all comers in the classes for pears and grapes, and won the challenge cup for grapes. His Muscats were indeed examples of good culture. Mr. S. High, gardener to J. A. Christie, Esq., M.P., had the best dish of Emile de Heyst pears. There was a profusion of vegetables. The best collection was staged by Mr. T. Bentley, gardener to Mrs. Barker-Hahlo. One was pleased to see that the classes for allotment-holders' produce were keenly contested and some extra well grown specimens staged.

The trade helped considerably in making the show a success. Messrs. Daniels Brothers, Limited, Norwich, had a great display of apples, and side by side with these were specimens of the fruit trees they are now supplying, healthy and vigorous in appearance. Suttons had a display of vegetables and a fine bank of potatoes. Allwood Brothers and Mr. C. Engelmann had carnation displays. Keith, Luxford and Co. had a fine show of chrysanthemums. Clibrans made a speciality of winter-flowering begonias. Messrs. A. Reeves and Co. had a good display of fruit and fruit trees. Mr. R. Winder had berried shrubs and roses. Reamsbottoms were there with their ever popular anemones. The East Norfolk Fruit Growers' Association displayed a great collection of apples grown by its members.

Captain Sandys-Winsch, the secretary, had carried out the arrangements exceptionally well.

AYTCH-PEA.

THE NATIONAL DAHLIA SOCIETY

ALTHOUGH there was a small attendance at the Annual General Meeting of the National Dahlia Society, those present made up in enthusiasm what was lacking in numbers. The Society seems to be in a prosperous condition, for there has been a good increase in membership during the past year and the balance of £54 is another cause for congratulation. But the Society has experienced a serious loss in the resignations of its Hon. Secretary and its Hon. Treasurer, both of whom have done so much towards the prosperous condition of the Society. Although Mr. W. Stephens has been Hon. Secretary for less than a year he has, during that short period done an immense amount of work for the Society. But most unfortunately his health broke down immediately after the show and compelled his resignation. Mr. W. J. Chittenden of 2, Dents Road, Wandsworth Common, S.W.11, is the new Hon. Secretary. Mr. John Green, who has been Hon. Treasurer for fourteen years, was also compelled to resign for reasons of health and he is succeeded by Mr. D. B. Crane. The President, Mr. Reginald Cory, and the Chairman of Committee, Mr. J. Cheal, were both re-elected as also was the Committee with the addition of Mr. J. Green and Mr. R. Findlay.

TREATMENT OF OLD ORCHARD TREES.

SOME of our old orchard trees are retained because they are old favourites, some on account of their bearing qualities—though, probably, the fruits may not be of really good quality—and many are retained because the owner neglects his fruit trees generally. Old, useless trees should be discarded and uprooted, the branches formed into faggot wood, the trunks and main limbs into fire-logs. "Very drastic," some reader may remark; maybe, but it is the only right way to deal with such specimens. A few fruits are borne, two years out of four, on the outer branches, the individual trees cover many square yards of valuable ground which would be better occupied by young stock of the newer varieties. There are, now, good selections in our nurseries; more fruits of higher quality would be produced on the same ground with a minimum cost as regards labour and a maximum amount of satisfaction as regards yield of fruits. The present is a suitable time for dealing with the matter, and the carrying out of all such renovation work.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

PLEASE REMEMBER TO MENTION "THE GARDEN" WHEN ANSWERING ADVERTISEMENTS.

CORRESPONDENCE

FRUITING OF RHODODENDRON NOBLEANUM

SIR,—Your correspondent "P. D. W.," in THE GARDEN of November 1st, page 752, asks for the experience of others as to the natural seeding of this old hybrid. As I write I have before me a branch bearing seven capsules taken from a plant growing here in a large bed of this early-flowering plant. Fruiting branches were not by any means common on the plant, and only two out of about twenty specimen bushes bear capsules. These are well developed, about three-quarters of an inch long, and are now shedding a quantity of seed of a fat and heavy appearance, some of which we shall sow to test its germinating qualities. Seeds of this hybrid are never gathered, and it is undoubtedly a shy fruiter here. This may be due to the early-flowering habit, the flowers generally being subjected to the frosts usually occuring while the plant is in bloom.—R. L. H., *Edinburgh*.

CATALOGUE DESCRIPTIONS.

SIR,—If "Claremont's" letter (page 782) is intended seriously it implies that he considers that he knows the nurseryman's business better than those who live by it. That may or may not be so; but surely when he asks that a trade catalogue, besides furnishing cultural and other particulars about novelties, should also "enlarge upon the merits of older plants," he is demanding a handbook to be supplied gratis. Now the dictionaries explain a catalogue as "a list set down in order," and it is a great convenience to customers when they have such a list to refer to. I often marvel at the clearness and, in many cases, the beauty, of the catalogues distributed by nurserymen, especially having regard to the greatly increased cost of printing in recent years. Surely any tradesman may reasonably expect a customer to know the sort of goods he wants to purchase, be it grocery, whisky or what not, and considering the vast amount of literature upon every branch of horticulture at the disposal of all of us, there is not much excuse for anyone who, desiring to furnish his borders, chooses to continue in ignorance of the character and requirements of plants offered for sale.—HERBERT MAXWELL, *Monreith*.

SIR,—With regard to your most useful and interesting subject of catalogue descriptions, it strikes me that a practical, and at same time profitable, way out of the difficulty would be for a firm of horticultural printers to edit a complete set of descriptions, habits and instructions on each item as to soil, flowering time, position, etc., as in any of the best books published; arrange all in the same order (1, 2, 3, 4, etc.), set in small, clear type, electro them in quantities, catalogue them with distinctive numbers, and supply all firms with the ones they list for insertion after the names and prices. All growers issuing lists would pay willingly a reasonable all-round price (say 2s. 6d. or 3s.) each, and the saving in composition in printing would fully recompense them for the payment of, say, two or three hundred stock electros which would last for several years' lists of course. From the buyer's point it would be ideal and from the grower's point, as already shown, most advantageous. A word as to the point of view of the publisher of these "stock electros": The expense would be heavy and the work in compiling ditto, but if all nurserymen and growers were circularised their co-operation should be assured. It might even be taken in hand jointly by the issuers of catalogues to publish the set themselves and the printers to sell on commission. Of course, the matter would be copyrighted and responsibility for errors guarded against by a footnote explaining the source of the descriptions. Well, Mr. Editor, what do you think about it?—PRINTER-GARDENER.

COLVILLE BLANC APPLE.

SIR,—If Mr. W. Chamberlain, who refers to a former correspondence in these columns on the above apple, will send me his full address I will forward the apples and give the information for which he asks. The reply sent him has been returned from the Post Office "insufficiently addressed."—F. T. FOSTER-TREVILLE, *Liskeard, Cornwall*.

TROPICAL CORNWALL.

SIR,—This illustration, which may be of interest to readers of THE GARDEN, represents an Indian summer's night on Mount's Bay, Cornwall. The picture was taken by real moonlight from a hillside garden at Penzance on October 13th at 9 p.m. The moon in the picture is real.—T. E. CORIN, *Penzance*.

AN OCTOBER SCENE AT MOUNT'S BAY, CORNWALL, FROM A HILLSIDE GARDEN.

ON COLCHICUMS.

SIR,—I should like to make a suggestion to those who do not like to see the delicate blooms of colchicums—single or double—lying on the ground as a result of rough weather.

If any who grow them have also mahonia bushes which they can afford to plunder, I should advise them to break off 6ins. to 8ins. from the tips of the branches and push them in all over the clumps of bulbs so that the leaves cover the ground at a height of about 3ins.

I think it is advisable to do this when the white noses just break the surface. The blooms will then force their own way up through the leaves and will retain their erect position and keep their freshness in a way that will please the grower. It will be found, I think, that the glossy leaves lend an additional charm to the clump.—GARDEN.

EUPATORIUM WEINMANNIANUM.

SIR,—In THE GARDEN for November 22nd Sir Herbert Maxwell mentions this interesting shrub as being grown in a garden in the West of Scotland. One seldom finds it mentioned in gardening literature, and it is certainly not grown in many gardens where it would be appreciated were its attractions once discovered. It is evergreen and a rapid grower, so it soon forms a bush four to six feet high and as much in diameter. It bears cutting back well and is suitable for planting as an informal hedge in sheltered gardens. The flowers are borne in the greatest profusion in creamy white corymbs and are strongly and curiously scented. It is quite a pleasant scent, unlike anything else in the garden; it has been compared with coconut oil and bay rum, but does not suggest either of these to the writer. But the greatest charm of this eupatorium lies in the way butterflies crowd to its blossoms; it is delightful to watch numbers of Peacocks, Red Admirals and Tortoiseshells with an occasional Painted Lady or a Speckled Wood jostling one another to feast on the nectar. If one could plant a sunny corner of the garden with this fine South American eupatorium, the low-growing Buddleia variabilis nanhoensis, Aster Climax and Sedum spectabile atropurpureum in front, one would be certain of adding a great deal of interest to the autumn garden by the number of exquisite and perfectly harmless butterflies which would gather around the flowers.—N. G. HADDEN, *West Porlock, Somerset*.

SAXIFRAGA FORTUNEI.

SIR,—For many years I have attempted to grow this interesting and hardy plant in the open with very indifferent results. As a rule, its quaint late flowers, as well as the succulent foliage, are spoiled with the first touch of frost, and the only way to enjoy them is to protect with a small frame or bell-glass. I potted up a plant or two, but was not satisfied with the result, especially after seeing some potted plants grown by a friend. I then learned that this plant likes good rich soil to grow in, but even with this knowledge I had only poor flowers, so I turned out the plants this spring, and soon saw where I had been at fault. S. Fortunei is to a great extent a surface rooter, and as such wants the rich soil at the top of the pot and as a top-dressing; then, as in my case, this back-end one has massive foliage and a wealth of bloom like a white mist a foot or more high, and continuing in beauty for a month or more.—T. O. WALKER, *Carnforth*.

ECONOMIC PROPERTIES OF THE OAK.

SIR,—Two great needs of the world at the present time are more food and more wood, the former a bodily, and the latter (as a basis of paper) a mental necessity. These needs would be largely supplied by the development of an oak bearing acorns fit for human food and producing wood which might either be used for pulp or timber that would set free other forms of wood to be used for pulping.

Acorns of various kinds of oak are habitually used in many parts of the world and have been often eaten in times of famine. The acorn of the Quercus ballota, a native of North Africa, is regularly brought to market in Algeria and southern Spain; that of Q. excula is eaten in Italy; the Q. Chinquapin of North America is especially recommended for esculent cultivation; and other American and Himalayan species produce edible acorns.

A food prepared from acorns in Turkey is, I believe, especially appreciated by Turkish ladies for its fattening properties. Oil, too, is made from acorns in considerable quantities in various parts of the world, and is used in cookery. Some trees of the common oaks are said to produce acorns that are as sweet as chestnuts, and even those that are bitter are stated to become sweet by being buried for a time.

These facts in regard to oaks and their acorns suggest that under modern horticultural plans of improving and evolving fruits, an acorn might be developed that should be thoroughly edible, adding immensely to the food resources of the world and especially of this country. I venture to suggest that the attempt to produce such a great benefit to humanity is worthy of the efforts of a society formed for that purpose.—H. RAYNER, *Hampstead*.

BORDER CARNATIONS.

SIR,—In the issue of THE GARDEN for November 22nd your correspondent, Mr. R. Morton, says, *re* Carnations, "I do not consider any yellow self in commerce an ideal outdoor plant." My experience is quite the reverse as regards Border Yellow, of which, last year and the year before, I had a wonderful show, the admiration of all my friends. This season none of my carnations has done so well, owing, I think, to the constant wet weather, which rotted the buds.—J. W. ROBERTS, *Bognor*.

A NOVEL METHOD IN GREENHOUSE HEATING.

SIR,—I have a greenhouse, from which I wished to exclude any frost, and I applied to our electric light company to supply me with a self-regulating plant that would switch on at about 34° Fahr. and switch off again at about 42° Fahr. They have done so, and apparently it acts perfectly. We have not had many frosts since it has been installed, but I have never found the temperature below 38°, and the other day I was watching and it switched off exactly at 42°. It takes up little room, a small instrument connected with the town current, regulated by a sort of thermometer, which switches the current off and on to two electric radiators, one at each end of the greenhouse. The saving in labour, burning of coke often uselessly, and anxiety as to fires, is very great. I have never seen this plant advocated previously, so think others may like to hear of it. The first instrument supplied to me switched on at 34° Fahr., but did not switch off till between 70° and 80° Fahr. This was much higher than I required, so they changed it; but others may prefer the higher temperature.—X.

NOTES FROM CONTRIBUTORS

NOTES FROM THE PYRENEES

THE summer session of the Société Botanique de France was held this year in the Pyrenees, and July 20th found us being received at Toulouse by the Faculté des Sciences of that old university. From there we went, under the direction of Professor Gaussen of Toulouse, to those scarcely visited mountains, where many interesting discoveries were made. At Foix was found the rare Æthionema pyrenaicum, while another day at the Quié de Lujat, above Ujat-les-Bains, we found the other rare Æthionema ovalifolium, which was thought to be Oriental. At the same place many curious forms of Sempervivum and the rare Alyssum diffusum (Tenore) were discovered. Fields of bright magenta snapdragons growing there under the woods and the darkest forests astonished me very much. The Genista Scorpius—very spiny and bushy—haunted the dry slopes everywhere with Astragalus monspessulanus, Centranthus angustifolius (sweet valerian), Lavandula pyrenaica (a Pyrenæan form of L. vera which differs by its longer white calyx and the diffuse ramified stems), Scabiosa pyrenaica, Sideritis pyrenaica, etc.

Another day we set out to the Port de Saleix (Port, from Porte=door, means in the Pyrenees a path or col) to find the rare Gentiana pyrenaica, which is a very curious species with its corolla, like a little cup, and its accrescent pistil. It forms dense tufts of deep green fine foliage and seems to be rather abundant in some places, growing just in the same manner as our G. bavarica. In the rocky walls of the "Port" were rare finds, such as Dethawia tenuifolia (a finely cut Umbellifer), Saxifragas media, cæsia, aretioides and the hybrids. Two interesting little shrubby forms of the Thymelæaceæ allied to the daphne are there: Passerinas calycina and dioica, which are rarely seen; the Passerina nivalis I found earlier at Gavarnie. These tiny shrubs are interesting and are very ornamental in the rock garden. Oxytropis pyrenaica is abundant there, too, along with Potentilla alchemilloides, with its pure white flowers and its beautiful leaves, mixed with the dwarf Columbine Aquilegia pyrenaica and the delicate-coloured Geranium cinereum, which adorns the rocks everywhere.

We then travelled on to Estours and the Port d'Aula (6,880ft. altitude) to find other treasures, such as Erodium petræum, Jasione humilis, Ranunculus Gouani (a big form of montanus), Potentilla nivalis with its silver white foliage, of which the natives make tea. We tasted the roots of Trifolium alpinum, which is here called "réglisse" because the root is very sweet and is utilised to sweeten drinks. It is, indeed, curious that the same root in the Alps is quite destitute of sweetness. Hypericum nummulariæfolium is everywhere in the shady and damp rocks hanging with its branches covered with bright yellow flowers in company with the delicate Reseda glauca, Myosotis pyrenaica, Brunella grandiflora, Betonica alopecuros, etc.

One day we paid a most interesting visit to a park at Siradan. There the trees, thanks to the damp atmosphere and the mild climate, attain very large dimensions, and the collection, made three-quarters of a century ago, is very complete. All the conifers known to me were there, with others which I have never seen elsewhere, and they attain such proportions that they are worth attention. A Cryptomeria elegans is nearly 40ft. high and the japonica still bigger. A magnificent group of three Thuyas gigantea (Lobbii) covers an area of 280 sq. ft. with their branches, some measuring 20ft. long. The collection of trees here contains conifers of the north (spruces) and of high altitudes, such as Pinus Cembra (Swiss pine) and those from Chili and California, the olive tree and laurus, Punica granatum, Buxus balearica (very high and strong), the rare and local growing Quercus Toza, the big Magnolia glauca, Maclura, Juglans nigra (bearing mistletoe), Libocedrus decurrens, a close ally of Araucaria, etc. In the neighbourhood we went to visit a Mediterranean station where the Quercus coccifera and Ilex, Pinus Laricio, Cytisus capitatus, Oxyria alba, Asparagus acutifolius, Coris monspeliensis and many other South European plants were mixed together. On a wild slope at the base of the hills we found here and there the beautiful pink-flowered Calystegia sylvestris rosea as figured and referred to in August 30th issue of THE GARDEN (page 607). It bears pink flowers (of a soft pink) much more delicate than those of Calystegia dahurica. I found this variety often in the Pyrenees, and must add that many plants have the tendency of darkening their colours. For instance, Saponaria officinalis and Dianthi monspessulanus, deltoides, barbatus and hirtus are deep pink.

We went to Frontignan to see the gigantic chestnut (Castanea vesca), its trunk measuring, as we found, nearly 30ft. in circumference at 3ft. from the base. From Luchon we went to Superbagnères, where we found the most luxuriant vegetation one can imagine—I would call it the "macroflore" of the Pyrenees. Hesperis matronalis alba, Lunaria rediviva, Lilium pyrenaicum, Lactuca Plumieri, Ranunculus platanifolius and R. aconitifolius, Valeriana pyrenaica, Myrrhis odorata, Geranium phæum and G. pratense attain large dimensions, together with Impatiens Noli Tangere (especially under the trees) and the rare Aspidium Braunii, which grows in the Vallée du Lys. The north facing walls are covered with ramondia, and the Welsh poppy adorns the slopes everywhere. The white form of Campanula latifolia is there a real beauty with its long pure white spikes of flowers, and the Gentiana Burseri with its yellow bells speckled with brown is exceedingly pretty. Hypericum Richeri I have never seen in such abundance and so bright, while Scrophularia pyrenaica was also at its best.

The session was brought to a close with a lecture by Professor Gaussen at the Laboratory of the University of Toulouse, which is at Jouéou (5,200ft. high). We found there many more interesting things, Scilla Lilio-Hyacinthus, Lilium pyrenaicum (of enormous dimensions, I measured one of 8ft.), Anarrhinum sempervirens, Dianthus barbatus very bright in colour, Fritillaria pyrenaica (as seeds), Senecio adonidifolius, Pedicularis pyrenaica, Cephalaria alpina, Angelica Razulii, etc.

I then left for Cerdagne, where I went alone to botanise in that real paradise of the botanist. From Perpignan to Mont Louis the slopes from the railway are adorned with a great collection of plants, such as Bupleurum fruticosum, Cistus albidus, C. laurifolius, C. umbellatus, Genista horrida, Capparis spinosa, the many pinks (Dianthi hirtus, pungens, Seguieri, Geranium pratense, etc.). From Mont Louis (you gave a view in THE GARDEN last spring of the town and environs) I went to the little Valley d'Eyne and there I found the *crême de la crême* fields of Fritillaria pyrenaica, of Genista anglica, Senecio adonidifolius, slopes of rhododendron with all their thick foliage,

Digitized by Google

rimula graveolens (very large form), Adonis yrenaica, Delphinium elatum (shorter and ghter blue than the alpine one), Senecio ourneforti, Aconitum pyrenaicum, Aquigia pyrenaica, Saxifragas geranioides, aquaca (adscendens), umbrosa, Linum alpinum, mpetrum nigrum, Azalea procumbens, etc. the meadows the delicious Gentiana yrenaica and G. brachyphylla, Campanula ifolia, Molopospermum cicutarium, Trifoum alpinum, phyteuma and ranunculi. On gher situations—the way is climbing at ooft. to the Port de Nuria — Senecio icophyllus makes large carpets of elegant ver foliage with brilliant orange flowers—beauty—and Saxifraga oppositifolia grandiora or pyrenaica adorns the north side of e rocks. The curious Iberis spathulata ith light pink flowers, the very curious alium cometerhizon, which makes very ort and dwarf tufts with deep red flowers, e Jasione humilis (a beauty very dwarf too) d the Ranunculus parnassifolius, with its r. angustifolius, are the jewels of the errier. Erodium macradenum adorns the cks of the limestone part, and Papaver yrenaicum with its multitude of orange owers enriches the landscape.

ut, above all plants, the axifrages call for special dmiration. Here many botnists, such as Luizet, Soulie nd Sennen, made their best bservations and have made uite a collection of types. I ound at the Port and in the icinity Saxifragas capitata, ajugæfolia, adscendens, androsacea, entadactylis, varians, mosata, nervosa, intricata, Iratina, pubescens (in its best orm), obscura, media (anything igher up the limestone), enuifolia, planifolia, oppositiolia. The Jasione humilis is t the top a real beauty, very dwarf and bushy blue masses!

By returning to Eyne in he evening I found for the irst time in my life Potentilla ruticosa with its brilliant big yellow flowers, much better than in cultivation, and enormous tufts of Iberis Garrexiana. The Pyrenees Orientales are the richest part of the chain, and I long to return there, as I was in a great hurry the last time. Antirrhinum Asarina was everywhere over the walls near Mont Louis.—H. CORREVON. *Geneva.*

SOME PLANTS THAT NEED NOT BE STAKED.

THE rough and inclement weather experienced this past year has emphasised the worth of those plants which need little or no staking. When it can possibly be avoided, I am always much averse to staking, owing to the great expenditure of time and trouble entailed. Unless, too, it is carefully done, the true beauty of a plant is frequently spoiled.

Despite the succession of heavy rains and strong winds during the flowering season—and my garden is an exposed one—several plants in the border have demonstrated very well indeed their ability to withstand such adverse conditions without the assistance of staking of any sort.

For the last few weeks Rudbeckia Newmanii has presented a neat and attractive appearance, the bright yellow flowers of stellate form standing up well on their stiff, erect stems. A few clumps of this well known flower are most useful at this latter end of the season.

Plants of Anemone japonica have been no trouble at all despite day after day of rain and high wind. These graceful plants seem to come up smiling after each onslaught.

Helenium pumilum magnificum and the variety H. Crimson Beauty stand up well, the latter particularly. They cannot throw off a combined attack of wind and rain in the same easy way as do the two foregoing examples, but staking was not resorted to until it was seen that the rough weather might eventually spoil their beauty.

In the case of herbaceous phloxes comparatively large clumps of certain of the older varieties stood up against the rain and wind quite well with no support whatever, but most of the newer sorts seem to lack the constitution of the older varieties and had to be staked.

Earlier in the season the tall and graceful Thalictrum aquilegifolium needed no support, although it grows in my soil over 5ft. in height. Most of the lupins were not staked, but all varieties are not equally reliable in this respect. String tied round the lower part of each clump has, as a rule, however, been found quite effective in most instances. First year plants of sidalcea stood the strain well without being staked, but older plants had to be supported.—HOWARD H. CRANE, *Highmead, Cheney Lane, Eastcote, Middlesex.*

TALL AND ELEGANT FLOWER SPIKES OF PRIMULA LITTONIANA.

AMONG THE ASTERS.

THERE are certain charmingly coloured compositæ, which when the weather is not so severe as to destroy the blooms give a bright effect throughout November, especially the earlier part of the month, and among these most frequently seen are the asters, or Michaelmas daisies as they are usually called. No one should be without them on the hardy plant borders if they really desire to have a joyous coloured show in the late autumn. The flowers of asters range in size from tiny things to the giant-like and wonderful coloured blooms of Aster Amellus King George; this comparatively new variety, which has rich deep violet blooms gives one the impression that perennial aster flowers may one day rival in size those of the annual sinensis strains.

The fine foliage and shape of the florets with the early blooming qualities of Aster acris mark it out as one apart from the other members of the group; as in an ordinary season it gives a good display about the middle of September. Michaelmas daisies of the Amellus strain are usually well furnished with clean and healthy foliage of a pleasing green shade. No one would plant Aster ptarmicoides for a floral display, but its fine feathery appearance warrants it a place in the borders. A. cordifolius is a floriferous, graceful and very useful variety and exhibits, like A. multiflorus, a step towards the larger-bloomed kinds. A. cordifolius when left unstaked or untied spreads its long stems clad with dainty flowers o'er the grey green growths of the catmint and the silvery carpet of Stachys lanata. Those on the look-out for a compact-growing and very floriferous aster should feel elated over A. Amellus elegans; it has medium-sized blooms of a soft blue; but really the last portion of the name properly denotes its qualities. A. paniculatus is a taller-growing variety with fine free flowers of a lavender blue most suitable for cutting. No collection of these daisies would be complete without a light coloured or white form, and the variety Mrs. John Wood well maintains the floriferous qualities of the aster family. It is one of the tall-growing kinds although not a pure white. None, however, is more striking at this late date than the tall and stately variety known as Mrs. S. T. Wright, with its purple or rosy-purple flowers.—DAVID ARMSTRONG.

PRIMULA LITTONIANA.

THE enclosed photograph, showing Primula Littoniana, was taken at the beginning of August this year. These primulas were raised from seed in the spring of last year and the seedlings planted out in their position in July. I find this primula dies down in the winter and is the latest primula with me to show any signs of growth in the spring. It was the second week in May this year before it started to push up its oval foliage; but when it starts to grow it does so very quickly and begins to flower in two months from the time growth appears above ground.

Primula Littoniana is a most striking species with a tall powdered stem terminated with a bright red spike that is very attractive before the flowers expand. After a time the pendent little flowers begin to open, and vary in colour from lilac to deep purple.

The tallest stem shown in the photograph measured 33ins. high and the flower spike 9ins. long. These plants may be the species named Littoniana robusta.

This primula is growing in damp peaty soil facing north alongside of primula vincæflora, and has set plenty of seed this autumn. —A. H.

AUTUMNAL ROSES.

THE following have been picked here today, November 13th, in most cases in perfect condition. Lieut. Chauré, Capt. Hayward, Col. Oswald Fitzgerald, Padre, Capt. Ronald Clerk (hitherto marked down as worthless has given blooms quite worth having in November), Zépherine Drouhin, Mme. Pierre Cochet, A. R. Goodwin, Mme. Falcot, Souvenir de Georges Beckwith, St. Helena (especially good, a perfect little buttonhole rose of faultless shape), Commander Bartie, Etoile de Hollande, Macbeth, Serge, Bassett, G. Amadee, Hammond, Dr. Joseph Drew, Papa Gontier, Prince Charming and Socrates. Many others were blossoming on November 5th, such as Souvenir de Claudius Pernet, Safrano, L'Ideal, A. N. Mellersh, Raymond, Waltham Crimson, Gorgeous, Sovereign, Ariel and Rouge Angevine.—EDWARD SHOOSMITH, *Halland, Sussex.*

GARDENING OF THE MONTH

FLOWER GARDEN.

HERBACEOUS BORDERS.—Cut down remaining flowers and tidy borders. Fork lightly in between the plants. Take care not to disturb any bulbs.

ROSES.—Finish planting soon in mild weather only. Just cover the union of the stock and scion. Spread out the roots. Plant firmly, but not deeply. Spray roses infested by black spot with copper sulphate solution. Use 1oz. of copper sulphate to 2 gallons of water and spray in mist form the bushes and the soil round the base. Gather up any fallen diseased leaves and burn. Finish pruning ramblers. Place straw or bracken round the roots of tea roses to prevent injury by frost. Draw up soil round stems of other roses, taking care not to remove any soil from the roots. In cold districts place bracken among the branches of standard roses.

RANUNCULUS.—Cover autumn-planted roots with leaves to protect from frost.

ST. BRIGID ANEMONES.—Cover with twiggy branches to give slight protection to the leaves and buds.

FRAMES.—Guard against damp and cold. Ventilate only on warm days and give very little water to the plants. Pick off dead leaves and clear away decayed cuttings. In frosty weather cover the sashes with mats at night. Feed violets occasionally and stir the surface soil. Give water only when quite dry and ventilate carefully according to the wind. If damp gets in sprinkle a mixture of powdered lime and charcoal round the plants.

HARDY FRUIT.

PLANTING.—Continue during suitable weather.

PESTS AND DISEASES.—Weave strands of cotton round gooseberry bushes to prevent bullfinches destroying the buds. Spray trees infected by American blight or scale with Woburn Wash. Ingredients: 1½lb. of copper sulphate, ½lb. of quicklime, 2lb. of caustic soda, 5 pints of paraffin, 9½ gallons of water. Dissolve copper sulphate in water in a wooden vessel, put lime in 1 gallon of water in another vessel. Leave for a few hours. Mix, add paraffin and remainder of water and shake in caustic soda. Stir well and apply in fine mist form. Cleanse old orchards and any fruit trees with caustic alkali to destroy lichen and moss. Only use once in three years. Spray with a solution of 1lb. of 70 per cent. caustic soda in 10 gallons of water.

PRUNING.—Can be done in any weather. Spur back laterals of apples and pears to within two eyes of the base. Cut off unripened wood from the leaders. Prune fruiting standards lightly and thin out branches. Train young trees carefully. Keep centre of young bush trees open. Spur back laterals of plums and sweet cherries and leave some well ripened shoots of the current year's wood. Cut out completely unfruitful whippy shoots of pears.

PROTECTION.—Cover roots of peaches, vines and apricots outside with litter.

RE-GRAFTING.—Cut back main branches of fruit trees intended to be re-grafted next April. Select strong, well ripened shoots of varieties to be used as grafts and insert in soil or sand to keep the sap dormant until required.

VEGETABLES.

ASPARAGUS.—Bastard trench any new beds. Add a liberal supply of well decayed manure between each spit and, on heavy soils, road grit and lime rubble.

BROAD BEANS AND PEAS.—Draw soil up round the young plants.

CAULIFLOWERS.—Lift the remainder and store in a dry shed until required.

CELERY.—Protect by covering the ridges with litter.

PARSLEY.—Cover with a hand-light to prolong the supply.

POTATOES.—Set up a few tubers in boxes and place in a frost-proof shed for early spring supplies.

GENERAL.—Continue digging and bastard trenching and consider the question of rotation of crops. Add farm manure to heavy soils and cow or pig to light soils. Give a dressing of road grit, wood ashes or burnt soil.

SHRUBS AND TREES.

PLANTING.—Complete as soon as possible during mild weather the planting of deciduous and evergreen shrubs except hollies and rhododendrons. Prepare the ground well and allow to settle before planting.

PROTECTION.—Draw soil up round the stems of tender shrubs and wrap remainder of stem round with haybands. Cover tender climbers facing east with thin canvas sheets. Do not remove covering each day until the plants have thawed, as bright early morning sunshine on frozen plants is most harmful. Protect tender shrubs with mats supported on a light framework during very severe weather. Shake off snow from conifers to prevent the branches from being broken.

PRUNING.—Finish pruning Ceanothus azureus, Buddleia variabilis, Hydrangea paniculata, Cornus sibirica, Rubus biflorus, etc.

GENERAL WORK.

CONSTRUCT new borders, rockeries, rose-beds, walks, pergolas, etc. Wheel manure on to ground in frosty weather.

FRUIT STORE.—Examine, pick out decaying fruit. Damp down the floor to prevent the fruit shrivelling.

LAWNS.—Continue renovation and prepare ground for new lawns. Most soils need drainage. Place drainpipes 15ft. apart and 3ft. deep. Cover cracks at the joints with clinkers. Make the pipes slope very gradually to a pit filled with broken bricks. Level site and leave to settle.

PESTS.—Fumigate ground badly infested with wireworm. Use Vaporite or Kilogrub. Pick out wireworms from soil when digging and set traps of slices of potato, parsnip or rape cake 2ins. below the surface of the soil. Examine these traps daily.

PERGOLAS.—Examine woodwork and repair. Tar base of all posts.

SEED ORDER.—Send for catalogues and prepare lists.

SHEDS.—Clean out and tidy during wet weather. Examine tools and make list of new ones required. Overhaul and thoroughly oil all lawnmowers. Repaint labels. Tie stakes in bundles and repoint. Prepare hooks for layering.

STORES OF ROOTS, DAHLIAS, ETC.—Ventilate occasionally on a warm day.

STACK good fibrous loam, grass side downwards.

WALKS.—Put fresh gravel where it has become thin. First loosen the surface, cover with a good layer of new material and then roll well.

WASH and stack pots during bad weather.

FLOWERS UNDER GLASS.

GENERAL.—Avoid excessive moisture. Water early in the morning. Guard against mildew. Always use tepid water. Fumigate for red spider and aphis. Ventilate carefully. Close the houses early to conserve as much sun heat as possible. Do not pot plants this month if they can wait until next with safety. Thaw frozen plants very gradually. Cover with mats for a few hours and then [illegible] cold water. Protect from sun [illegible] Rapid thawing or syringing with warm water is fatal. Keep atmosphere dry and warm for flowering poinsettias, pelargoniums, freesias, lachenalias, etc.

CARNATIONS.—Ventilate at all times. Feed with liquid manure or soot water. Give an occasional dose of Clay's or Peruvian guano.

CHRYSANTHEMUMS.—Insert as many cuttings as possible. Purchase cuttings of new varieties. Pot, into 3in. pots, the early struck cuttings.

FEED primulas and cyclamen twice weekly with liquid manure and cinerarias with soot water. Take care not to pour water near the base of the latter, otherwise "stem-rot" will set in.

FORCE in pots Azalea mollis, Deutzia gracilis, lilac, dielytra, spiræa and roses. Bring into gentle heat.

GLADIOLUS.—Pot up into 5in. pots.

GLOXINIAS.—Shake out old corms, pot up in leafy compost and start in a temperature of 60° at night.

LILY OF VALLEY.—Pot up lightly crowns of Fortin or Victoria varieties, plunge outside to expose to frost for a short while, and then bring in for forcing. Give bottom-heat of 80°–90° and an outside temperature of 65°–70° at night.

NARCISSI AND TULIPS.—Bring in to warm temperature from the plunging ground when an inch of growth has been made.

FRUITS AND VEGETABLES UNDER GLASS.

APRICOTS.—Prune on the spur system.

FIGS.—Finish pruning, cleaning and top-dressing. Cut out weak and overcrowded shoots. Ventilate well except on cold damp days or in frosty weather. Scrub, with hot soapy water, trees infected with scale.

NECTARINES AND PEACHES.—Prune and thoroughly cleanse. Cut out old fruiting wood and lay in sufficient of the current year's wood to cover the required space. Keep every shoot perfectly straight and train the tree in the shape of a fan. Keep the shoots about 4ins. apart. Prepare border for young peaches. Take out 2ft. of soil, put in 9ins. of broken bricks and cover this drainage with turf, grass side downwards. Make border on a slight incline to allow excessive moisture to pass away. Fill with a compost in the proportion of twelve loads of best loam, one load of lime rubble, half a load of burnt ash and 2cwt. of ½in. bones. Plant four or five year old trees.

VINES.—Ventilate late vines well to ripen the wood thoroughly. Prune back laterals of midseason vines to within two eyes of the base. Prune when vines are quite dormant to avoid bleeding. Clean off bark and scrub rods with Gishurst Compound. Prepare border for young vines in the same way as advised for peaches, but use for the compost four loads of loam instead of twelve loads. Cement the bottom of borders for vines. Top-dress old borders with chopped loam and ¼in. bones.

CUCUMBERS.—Allow the plants to carry only a few fruits. Water with liquid manure when fruit has set. Keep temperature 65°–70° at night and the atmosphere humid. Ventilate cautiously.

DWARF BEANS.—Sow in 8in. pots in well drained compost. Grow in an airy position in a temperature of 65°. Syringe to keep down red spider.

FRENCH BEANS.—Make small sowings every few weeks to form a succession.

MUSHROOMS.—Collect horse manure for eight days, store in dry open shed for eight more days, turn frequently. Make up beds in mushroom-house. Tread firmly and leave until temperature has declined to 80° and then add spawn. Cover lightly with soil and keep atmosphere moist.

SIMPLE GARDENING

DIVIDING HERBACEOUS SHRUBS.

THE division of the roots of old clumps is a work that cannot be neglected if one is to be quite satisfied with the herbaceous border as a whole. The large border is more easily managed than the small one, because these plants require elbow room as it were, and cultivators are sometimes inclined to overcrowd them, wishing to include this gem and that one, too, and so on. It is a suitable time now to overhaul the border, to discard the exhausted and renew the vigorous roots; also, to enlarge the border where this can be done, making use of surplus good stuff and adding new. I am sure many readers have recently noticed the condition of the roots and flowers of such as Michaelmas daisies, and earlier, of phlox, to name two kinds. The outside portion of each old clump produced strong stems and large blooms, so it is advisable to discard the weaker central parts and retain the outer. Carefully lift and separate the roots, before digging up and enriching as much border space as possible and re-planting. Where the soi lis cold and very clayey it is a good plan to mix a compost of lighter material for a raised and warmer border and to transfer the divided portions of the clumps to it, arranging them in lines fairly close together for the winter months. In this temporary border leave them till next spring, when the clumps may be planted in their permanent quarters and thrive there. In the meantime the permanent border soil can be dealt with and improved.

PRUNING AND PLANTING DECIDUOUS TREES AND SHRUBS.

The decision to prune these subjects should be made during the summer months, when the leaves have fully developed on the new shoots. The specimens have a different appearance then; overcrowding can be easily observed and a note made as to the extent of the pruning necessary in the winter. In dealing with each tree or shrub due regard to its natural growth must be taken so that such natural growth will be maintained in the future. This is accomplished by keeping the balance of each specimen without crude formality resulting. The severing of large branches should be very carefully done, first with a saw then smoothing the wound with a sharp knife, taking care that the bark portion is neatly pared off. In some positions it is necessary to prune the trees or bushes very severely because the space is so limited. The resultant growth is, naturally, strong and the general appearance formal; this, in the circumstances, cannot be avoided. The planting of these trees and shrubs is a very interesting work. Unlike evergreens, they do not suffer from strong winds, even if the taller ones are left unstaked; indifferent staking is a very unwise thing. If a specimen is allowed to be blown to and fro, root action is considerably delayed the following year, whereas neat and effective staking is beneficial in every way. The specimens that are to be permanent should be planted first, the intervening space being filled afterwards. If wet weather prevails, and dry, dusty soil is available, a spadeful scattered on the roots before replacing the bulk of soil will prove beneficial.

ABOUT POTATOES.

Both seed and store tubers are very precious at the present time. In many parts of the country quite half of the crops rotted before lifting was completed, and decay has, in many instances, continued in the store shed. Those cultivators who grow potatoes on a small scale are very anxious as to treatment. Only where there are no other means of storing would I consent to store the eating tubers in heaps in open-air clamps. The shed store, this winter is the best, if covering litter is available in sufficient quantity to exclude severe frosts. It should not be overlooked that store sheds raised a few inches above the ground level are unsuitable unless a thick layer of straw be placed on the floor as well as on the heap of tubers. I remember one cultivator who stored some of his seed tubers on the floor of a shed of this kind and, although he had piled thick coverings on the boxes during a severe spell of weather, found, when the thaw came, that two-thirds of the tubers were soft and useless. There is always a cold current of air passing under such sheds, and when frost prevails it penetrates and does a lot of harm. Where eating tubers are still decaying I would recommend the use of dry lime. The heap should be carefully hand-picked, all diseased tubers taken away and the sound ones nicely covered with dry lime before the protecting material is replaced. The seed tubers require careful watching; they are all the better for exposure to light and air when the weather is favourable, but when it is not, ample coverings will do good, not harm.

LATE CHRYSANTHEMUMS.

Where high feeding has not been the rule, loss from damping is lessened, but there is sure to be some disappointment from this cause where neglect in regard to watering, ventilation and temperatures exists. Although frosts of six or seven degrees severity do not kill the blooms in unheated houses, they damage some of the petals. In the unheated house there is, more or less, condensation of moisture on the flowers and opening buds, and when they are frozen, ever so slightly, while in this condition, loss of petals will occur. There is no difficulty where the houses are nicely heated. In unheated structures the cultivator should ventilate very carefully, watch the weather closely and so expel as much moisture as possible without letting in cold currents of air. The right thing to do is to water, where necessary, early in the day; to open the front ventilators a little and the top ones wider; to close the front lights early in the afternoon and to leave a small chink of air at the top of the house all night.

GEORGE GARNER.

WHY is "HOMES and GARDENS" such a Great Success?

BECAUSE it shows greater House Comfort & Convenience —with less Labour and Expense.

THE SCIENTIST & THE PRODUCER

IT is an unfortunate but, perhaps, a natural occurrence that agricultural and botanical science is moving quicker than its discoveries can be put into practice. Scientists are advancing so fast in their achievements that ordinary mortals are unable to keep up with them. You constantly hear the producer, whether he be farmer, forester, fruit-grower or gardener, blamed for not making use of the most modern methods. The scientist has a good deal of justification for his complaint. Whereas manufacturers and traders always keep on the look-out for money-saving appliances and new methods of salesmanship, producers of products from the soil are notoriously conservative. One obvious reason for this conservatism is lack of capital. Another is that science has only really started to help the cultivator since the beginning of this century, and that from 1900 onwards the amount of discoveries about the scientific value of stocks, fertilisers, bacteria, various soils and so on has been so stupendous that the producer has been staggered and does not know where to start, or once he has started where to stop.

There is, however, one reason for the lack of co-ordination between scientist and producer, for which I think the scientist is largely to blame, and that is that the language they use is quite incomprehensible to ordinary mortals. There is no linguistic mean in which the scientist and the producer can meet on common ground. Each new text book or monograph becomes more complicated and more involved; in fact, few are produced in which there are not at least a baker's dozen of newly coined words or phrases. The scientists' answer is that they are an international brotherhood and that new ideas must be expressed in philological terms so as to be understandable in almost any language. This is surely forming the scientists into a very close corporation with a more definite cleavage every year between the specialist, and the ordinary well educated human being. Naturally the ordinary human has only a limited amount of time at his disposal for delving even into the outer fringe of the scientific side of any subject, but this does not mean to say that he would take no interest in it, if he could.

I was much struck the other night by hearing over the wireless a most excellent lecture on what the Rothamsted Experimental Station was doing for agriculture. It was a short address and lasted a bare twenty minutes, but I am sure that most of those who listened to it wished it had been twice as long. It was expressed in simple language, was lucid, and was intensely interesting. I have heard the same thing said about the lectures which members of the Rothamsted staff give at different agricultural and horticultural colleges and training centres. This proves that it is possible to interest the ordinary man in the scientific side of plant production. And yet there is nowhere, outside of scientific or technical journals, which he never sees, where simple explanations can be given. I know that on the East Coast of Scotland where most of the farmers are keen to try new improvements if they are minutely and carefully explained to them, they do not do so because they do not hear about them, or if they do, they do not understand. Even the Board of Agriculture leaflets, excellent though they are, are often couched in too technical language. The same applies to new discoveries in science which are applicable to gardening or to fruit cultivation.

So sure am I of the interest, even among beginners, in gardening as to the why and wherefore of the growth of a plant and their attendant ramifications that THE GARDEN is shortly going to begin a series of articles on the interior economies of plants. These articles are going to be short and will be written in the simplest non-technical language.

There is little reason why scientists should not give us a little of their knowledge with as few scientific terms as possible, and perhaps if our readers understood why and how a plant grows, as no doubt some of them do, a better understanding of modern discoveries may not prove such a difficult step to follow. Naturally, such discoveries and improvements are particularly important when applied to economic crops.

Meanwhile this does not do away entirely with my original plaint, that modern scientific terms are becoming year by year more terrifying. At the present rate of increase there will be an entirely new language in another ten years. It will be only recognisable as English by the occasional insertion on a page of an "and" or an "is." Perhaps philologists could help.

CHRISTMAS PRESENTS.

A correspondent has written asking me to draw attention to the value of plants as Christmas presents—actually he does not confine himself to plants, but includes trowels, a garden book, raffia, or an instrument for strangling slugs: and, after all, why should not these instruments be included, for Christmas presents are becoming more and more utilitarian every year? It is true that children are old-fashioned enough to object to finding a pair of boots or half a dozen collars in their stocking, but then, children at Christmas live in a world by themselves. Grown-ups are different, and the more useful the present the more they are pleased. Think how pleasant it would be to hang a sack on the end of your bed and find therein the next morning a ton of rock of exactly the right shapes and sizes for the rock garden you had been planning, all the plants to stock your herbaceous border for the coming year, and the lawn mower you have put off buying for the past two years. It is not an impossibility—provided the sack is large enough. I am much obliged to my correspondent for drawing my attention to this important point. E. H. M. C.

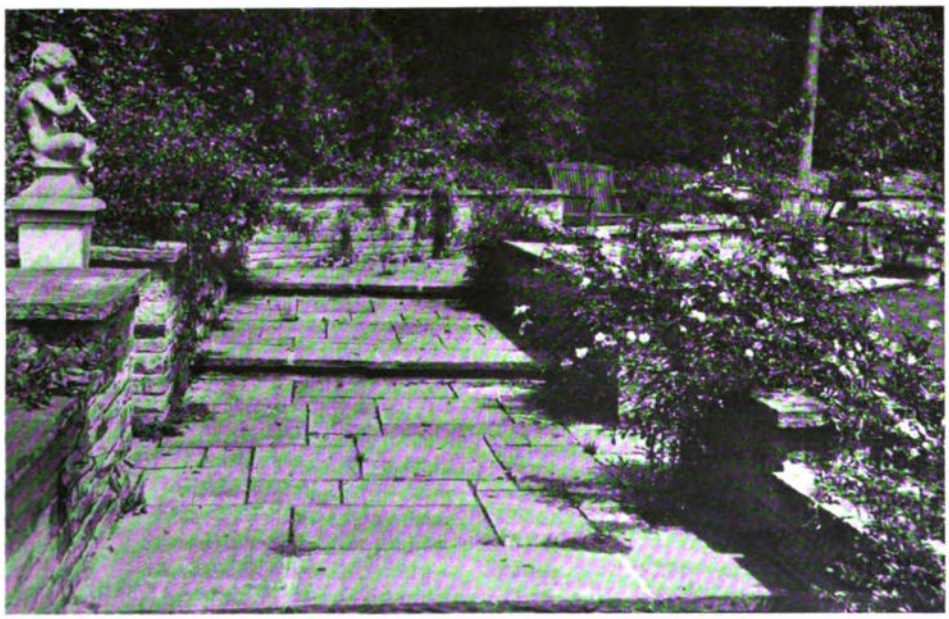
GARDEN DESIGN

SOME SUGGESTIONS ON PLANTING.

AT this time of the year the gardener's thoughts turn naturally to plants and planting. Nature, left to go her continuous unmolested way, clothes the earth with vegetation—wonderful alike in its myriad forms and the range of its ever-changing colours; from tiny close-growing mosses to tallest forest trees; from the plain greens and comparatively simple organisms of ferns and allied plants to the brilliant colouring and complex structure of orchids and many another plant; with herbaceous plants, for these cover the country-side as well as the garden, springing to fresh loveliness of flowering year after year; with deciduous shrubs and trees, full of changing beauty from the first sign of spring's delicate greens until their leaves fall, only to show the tracery of branches as lovely as the leafy dress they have discarded. Everything with wonderful fitness and economy of purpose carries on its destined work and helps to beautify the earth.

Nature plants in broad stretches and with harmonious colours, and, with due regard to proportion, the garden maker should follow her example and plant in masses. Many plants that singly or in small groups are unnoticeable or even unpleasing, can be very beautiful freely scattered in their green setting. To realise the value of massing one has to have numbers, as many as possible, of, say, Anchusa italica in lawn or grass against a background of green foliage of trees and shrubs. Seen thus it is far more effective and beautiful than in a mixed border. What, for want of a better description, I will call the wilder plants are best grown in this way. Many plants one feels are so much the result of cultivation that their place is in the border or gardens proper.

Everyone realises the beauty of narcissus in grass, and also that hyacinths and tulips would seem as wrong as daffodils seem right when growing naturally in some woodland walk or in the lawn. And to grow certain herbaceous plants in the same way is but an extension of the idea. Lupins, especially the blue, mauve and purple ones, are always effective massed by themselves. So also are iris, some of the veronicas, V. spicata and V. subsessilis, verbascums (mullein), eremuri and most of the hardy lilies.



THE PAVED GARDEN.

Most of the different varieties of any plant family mix together harmoniously, as also do the greater number of those plants that like more or less the same conditions. The many different forms of plant life are the result of ages of natural adaptation to environment. Aquatics and moisture-loving plants perish on dry banks, just as berberis, cistus, etc., dislike even an ordinary amount of moisture. In all their variety of colour and habit of growth roses in their different sorts tone, as do delphiniums, phloxes, berberis in their different sorts, also the varieties of most of the plant families. From all this the lesson to be learned is that, in our gardens, plants should be given their proper places and conditions and should be massed.

To consider more particularly the always popular herbaceous border. It may, with careful planning, be a continuously changing succession of colour schemes; or, if that is too ambitious a description, it can be more simply said that from an effective arrangement with any principal colour another and an entirely different colour scheme may arise as plants succeed plants in their flowering season. The clear yellows of early daffodils may be followed by the pinks and scarlets and wine and ruby reds of tulips, of which there are shades enough to form wonderful chromatic harmonies. Then for the summer there could be blues, cooler and welcome in hot weather, with grey foliage and perhaps pale yellow or pinks, these again to be succeeded by the deeper yellows and crimsons and bronzes of autumn.

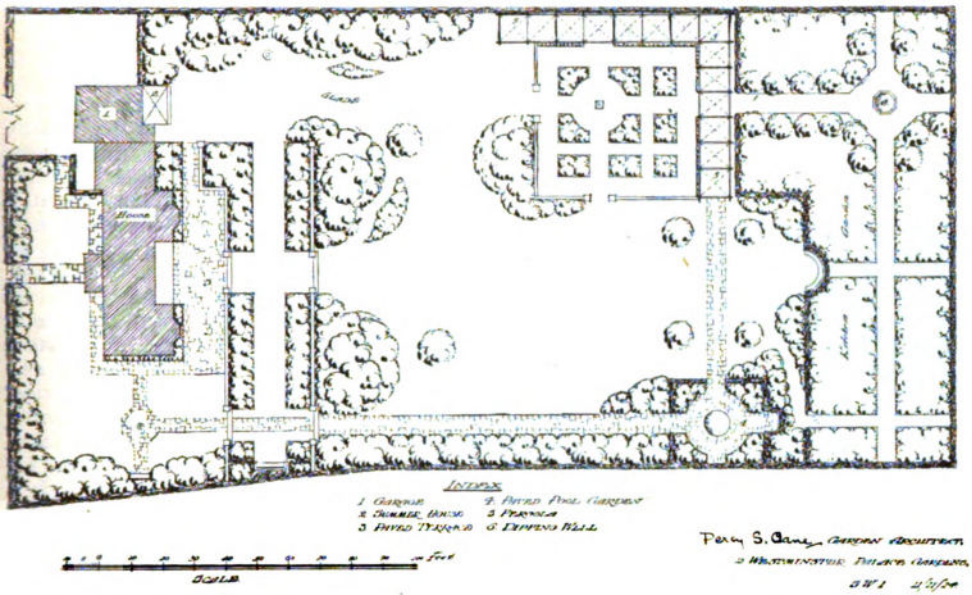
It is not always realised by the amateur how important form is in garden design. From the ground plan to the more important grouping of shrubs and trees it must receive first consideration, and colour must, so to speak, be built on to form. There must in all the different kinds of planting be first a proper balance, that is to say, the principal or outstanding masses chosen primarily for their ultimate height and substance must in opposite borders be balanced by other outstanding masses, not necessarily opposite or even alike, but so arranged that when fully grown a nicely related harmony and proportion is felt between the two sides.

Even in herbaceous borders weight may be given and their effect made richer by the introduction of evergreens or other shrubs, or perhaps some of the smaller flowering trees and bushes. These being outstanding, so far as form is concerned, should be placed with a careful regard to the attainment of a good balance, and as, unlike herbaceous plants, their growth is permanent and increasing, they are valuable alike in winter as in summer.

As well as the planting scheme as a whole, plants in the borders should form a succession of harmonious groupings each beautiful in itself and giving in its results every opportunity for individual taste and skill of grouping. The number of possible combinations is without limit. Grey foliage plants, and plants with white, very pale yellow, and the softer shades of mauve and lavender are valuable as foils for and to relate what might be, when used together, clashing stronger colours. Delphiniums, perhaps the keynote of the summer border, should be in as large groups as may be. They are lovely also against green only or in conjunction with cool whites, such as the large-petalled Chrysanthemum maximum, and in a warmer, stronger way with the bronzy foliage of Prunus Pissardii or Chinese peonies.

Foliage also is invaluable and should be considered in the colour scheme. Peonies are nearly as effective afterwards as while they are flowering, and should be placed so that their bronzy foliage tells in the general scheme. Yellow and bronze heleniums, red and yellow gaillardias, sulphur yellow anthemis, golden yellow coreopsis and orange marigolds will, with the coppery bronze foliage of peonies and purple-leaved Prunus Pissardii or the larger-flowered Prunus Moseri, make harmonies always pleasing and in sunshine glowing with light and colour. What may be described as autumn reds, beautiful as they are,

Digitized by Google



need to be carefully placed. Clear blues may be used with them most effectively, but they should not be near whites, pinks or any red approaching scarlet.

You may take the plant materials, endless enough in their numbers, and by finest artistry of arrangement make of them what you will. Your borders may be strong, glowing with gold and purple, red and blue; they may be softly delicate—mauve and greens and lavenders and white and palest yellows; they can be mixed to include all of your favourite flowers or they can be of one colour only, blues from the palest to the deepest shades, or yellows and gold and bronze; but, so long as they are harmonious in colour and the groups are proportional in size to the border or garden of which they form a part, the results must be, even in the simplest garden, interesting and beautiful. PERCY S. CANE.

THE CLASSIFICATION OF ROSES

BY H. R. DARLINGTON.

MANY GARDENERS FIND IT DIFFICULT TO UNDERSTAND HOW ROSES ARE CLASSIFIED INTO THEIR VARIOUS SECTIONS. IN THIS ARTICLE MR. DARLINGTON GIVES AN EXPLANATION.

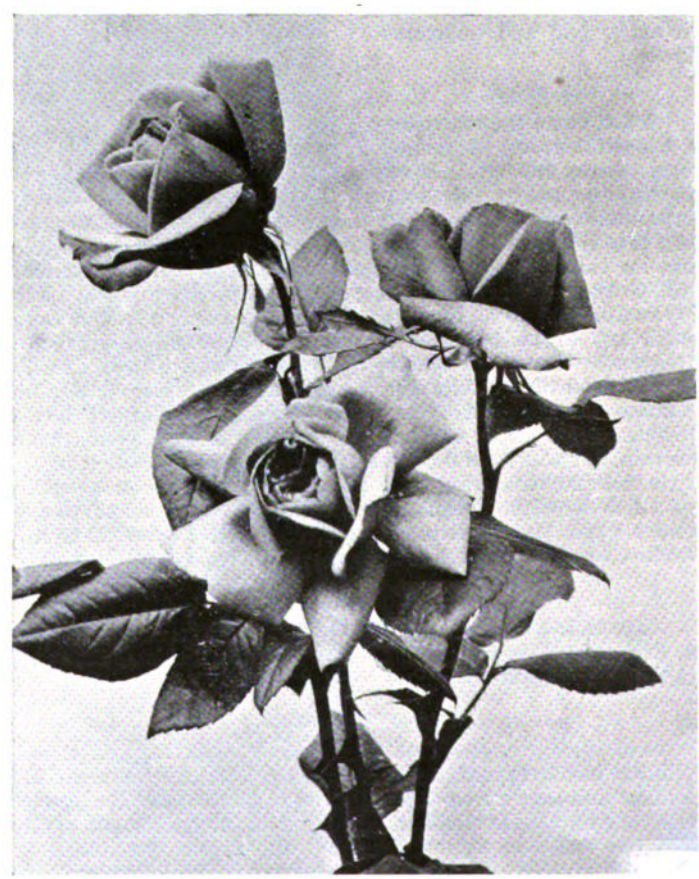
SOME ten years ago—shortly before the war—a good deal of discussion took place on the classification of roses, and several papers on the subject were contributed to the National Rose Society's Annual of 1914, under the general supervision of the late Mr. George Gordon.

The main object of classification of any group of plants should be, so far as practicable, to give some indication of the affinities, history, origin and character of the plants classified, in aid of detailed description, but it is clear there may be other objects. We may wish to indicate the use to which the different plants may be put in the garden, and their adaptability for special purposes, or the flowers that should be shown in particular classes at our exhibitions, or the most convenient arrangement of the different forms in a nurseryman's catalogue.

In the roses generally grown in modern gardens there is one clear line of difference that may easily be recognised, the one group being the bunch-flowered roses, which carry their flowers in a truss or bunch all opening more or less at the same time. This we find in the polyantha pompons, such as Mrs. W. H. Cutbush and Orleans Rose, and in many of the climbing roses of the Wichuraiana and multiflora sections, such as Dorothy Perkins and Crimson Rambler. The individual flowers in these cases are small and generally rather open in character. In the second group the flowers are much larger and borne more or less singly or, if they are carried in a head, as is often the case, they open successively and not all together. The flowers themselves are large and generally enclose the floral organs rather closely, giving the high pointed forms with which we are familiar in roses such as Avoca, Mrs. Theodore Roosevelt, Mrs. Herbert Stevens and the pink and white Cochets. However convenient a rough classification of this kind may be for certain purposes, it tells us nothing of the origin, and little as to the character of the individual varieties, and neither this nor any of the artificial arrangements that have been suggested have displaced the more orthodox groups, which have arisen with the development of the rose and give some general idea of the parentage and habit of the members of the different groups.

In this article I shall deal only with the more or less dwarf growers suitable for beds and borders and shall not include the climbing roses.

The modern rose has been produced mainly by crossing wild and garden forms of the rose with varieties of the China or tea rose, over a long period. Sometimes this was done naturally and later artificially. The results so obtained were re-crossed over and over again with China or tea roses. By this method forms have been produced which combine the hardiness and, in some cases, the fragrance of the older forms with the perpetual flowering character of the Chinas and teas. Fifty years ago garden roses had become very numerous



A TYPICAL ROSE OF THE PERNET GROUP.

Digitized by Google

in spite of those discarded. Of the list of some 200 names given in the Appendix to Lindley (1820), very few were left even then, and, if we except Spong, York and Lancaster, and Maiden's Blush they are probably all gone to-day. The classification of those grown fifty years ago had, however, become very complicated. Mr. William Paul in his great book on the rose garden enumerates no fewer than forty-one classes of garden roses, twenty-one of which he classes as summer flowering and twenty as autumnal. There was the reign of the hybrid perpetual which in size, and form, and often in fragrance, held easily the first place in the rose garden. To-day the hybrid perpetual is gradually disappearing — nay, it is almost gone, but it will be convenient to consider first this group and then the large-flowered kinds that are in effect replacing it.

A TYPICAL TEA ROSE.

THE HYBRID PERPETUAL.

The hybrid perpetuals still contain two roses of the first rank, Frau Karl Druschki, perhaps the best and most easily cultivated white rose, if one can forget its lack of fragrance, and Hugh Dickson, of delightful fragrance, fine form and habit. Mrs. John Laing, also very fragrant, is not far short of these two, and perhaps the wonderful flowering capacity and fine colour of Victor Hugo may keep it for a time, but it possesses in a marked degree that characteristic of so many of this group, namely, that to get one good rose there will be many bad and quartered flowers.

TEA ROSES.

Then come the tea roses, a beautiful group of refined form which, much to my regret, seem almost to be sharing a like fate so far as this country is concerned. British raisers have almost ceased to produce them. We had two good decorative teas in 1910, Lady Hillingdon and Mrs. Herbert Stevens, also an exhibition tea, Mrs. Foley Hobbs; in 1911, Alexander Hill Gray; in 1912, Mrs Herbert Hawkesworth; in 1914, Lady Plymouth and Mrs. Campbell Hall; since which I can only recall Mr. Prince's Muriel Wilson (Dr. Campbell Hall, 1922). There are two things against the teas as garden roses; nearly all the beautiful exhibition forms, such as white and pink Maman Cochet and Mrs. Foley Hobbs, hang their heads downwards, a habit which, while it protects the flowers from the rain, detracts from their garden value; and, in the next place, their delicate colouring and tender petals are readily spoilt by a few showers. Perhaps this country is too cold for them. Under glass the Bride and its pink sport, Bridesmaid, still produce lovely flowers, but they are of little use out of doors.

THE CHINAS.

The Chinas form a small group of even purer descent from R. indica than the tea rose. The old monthly rose and Comtesse du Cayla are good examples.

THE HYBRID TEAS.

This group began with Cheshunt Hybrid, 1873, and was followed by La France, 1877, a rose which became immediately popular and may be considered to have established the group. The very numerous members of this group merge imperceptibly into the teas the hybrid teas and the Pernet group (to be presently noticed). I think few rosarians could define precisely why Hugh Dickson should be classed as a hybrid perpetual and George Dickson as a hybrid tea, both roses making the strong autumnal growth chiefly characteristic of the former group.

Between the hybrid tea and the roses of the Pernet group the distinction is yet more difficult to find. Emma Wright, which is classed as a hybrid tea, is in the bud stage and that of the opening flower, indistinguishable from Severine, which is classed with the Pernet group. It is true that as the flowers fade Severine becomes slightly more pink than Emma Wright, and it has perhaps slightly more polished foliage of not quite so deep a green as that of the other, but these differences are not such as separate the typical members of the two groups. We must therefore be content to recognise that the boundaries of these groups are to some extent artificial and arbitrary and have been determined to a large extent by the judgment or fancy of the raisers.

In this group a very beautiful class of single or nearly single decorative roses has arisen of which Irish Elegance, Irish Fireflame and K. of K. may be taken as examples. In the best forms of these single or semi-single varieties the flowers are borne very freely on long sprays and open more or less in succession.

The perpetual flowering of the members of this group is obtained by the readiness of the plant to push up fresh growths from the flowering stem often before the first flowering is finished, this process being again repeated till the frost interposes and it is characteristic of the typical forms, such as Mme. Abel Chatenay in their second growth to produce from near the base a much branched panicle of flowers which open successively, and should be moderately thinned while still buds if good flowers are required. Although some of the group, such as Betty Uprichard and K. of K. possess little, if any fragrance, and must rely on their colour and form for their attraction, the group contains many highly perfumed flowers, notably Mrs. Bryce Allan and George Dickson.

PERNET ROSES.

The Pernet group has become both numerous and popular, the original member, Soleil d'Or, was obtained by M. Pernet Ducher in his search for a yellow rose by crossing the hybrid tea with Persian Yellow. The plant proved a strong grower, but the flower was very poor in form, and had little to attract except its colour. It was, however, succeeded in 1910 by Rayon d'Or and two years later by Mme. E. Herriot, often called the *Daily Mail* rose in consequence of its winning the cup presented by that paper at the International Exhibition of 1912. These have been followed by a numerous progeny, which, as above stated, merge into the hybrid teas. They are for the most part lacking in fragrance, but some few, such as Golden Emblem, possess a certain tea rose perfume. The typical members of the group are characterised by having many strong thorns, generally red and translucent when young, and large, dark and glossy foliage.

These roses were at first called Austrian hybrids, from a supposed connection with the Austrian briar. Later the National Rose Society adopted the inconvenient and incorrect Latinised form, "Pernetiana." It is better, however, to refer to the group as Pernet roses. No one nowadays speaks of Rosa Noisettiana, which is a case very similar to this.

Digitized by Google

MUSK HYBRIDS.

Mr. Pemberton has given us another new group of beautiful decorative flowers by working with the musk rose on our garden hybrids. Perhaps the best known and most useful of these are Moonlight and Pax, both of which grow well, but there are many others, and he may doubtless show us even better roses in the future.

POLYANTHA POMPONS.

The polyantha pompons form a gay little group, specially suitable for growing in small beds in place of bedding plants, for they are full of flower and bright all summer. Crossing the hybrid tea with R. multiflora, produced three groups of plants, first the tall-growing ramblers of which Crimson Rambler, brought out by Mr. Turner in 1893, was the first to attract attention. These were summer flowering only; next came an intermediate group which grew to 6ft. or 8ft. and flowered again in autumn. Of these Adrian Riverschon may be taken as an example. Finally came a dwarf group which flowered continuously through the season. One of the first of this group was Cecile Brunner, 1880, but it was the arrival of Mrs. W. H. Cutbush in 1906 which really established the popularity and value of the group as bedding roses. Since then the group has extended rapidly and includes such well known kinds as Orleans, Ethel Poulsen and Edith Cavell (the best crimson so far). For the most part they possess little fragrance, but Ethel Poulsen and Yvonne Rabier are delightfully scented. The flowers are generally rather open in character and produced in large heads, all the florets of which open more or less simultaneously.

The above groups in effect represent the dwarf roses of our modern gardens. For those who have room there are many others still worth growing. The dusky Tuscany, Maiden's Blush, Rosa alba, and R. altaica are all charming, but their place is outside the rose garden proper.

THE SOUTHERN BEECHES

BY W. J. BEAN.

NOTHOFAGUS ARE HANDSOME TREES WHICH SHOULD BE FAR MORE OFTEN SEEN IN OUR GARDENS AND WOODS. THEY ARE ONLY FOUND IN THE SOUTHERN HEMISPHERE AND ARE CLOSELY ALLIED TO OUR BEECHES.

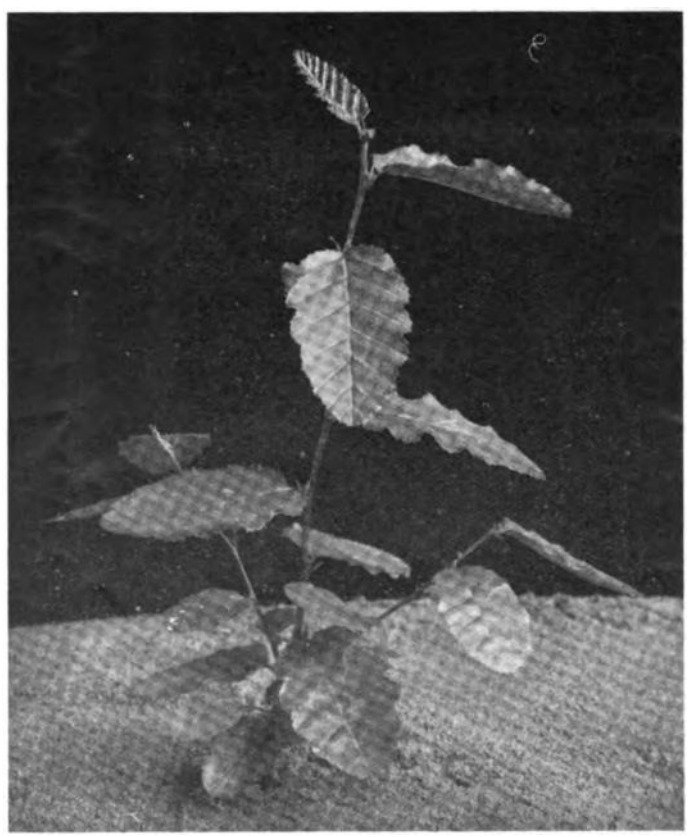
TO the tree lover, one of the chief anticipations engendered by the prospect of a visit to Chile or New Zealand would be the sight of the magnificent beeches growing in those countries. Until comparatively recently they bore the same generic name as the beeches of the Northern Hemisphere (Fagus), but there is now a general agreement that they should be distinguished by the name Nothofagus. Many of them are evergreen, while all the northern species are deciduous and their foliage as a rule is very much smaller. Apart from conifers, indeed, several species seem to stand alone among the large trees of the world by reason of the smallness of their leaves. There is the Chilean N. Dombeyi, for instance, which has a trunk 8ft. or 9ft. in diameter with leaves averaging 1in. in length; still more remarkable is N. Cunninghamii, a Tasmanian tree, which is described as attaining 200ft. in height with a trunk 12ft. to 13ft. in diameter, but whose leaves are only about ¼in. long; then N. obliqua is 120ft. high, and Menziesii and fusca 100ft.

In this country we admire these trees chiefly for their elegance and distinction, for, with the exception of N. obliqua, none of them promises to become of timber-producing size. But even in a small state they are very attractive, largely perhaps because they are so different from our northern type of tree. One of their characteristic features is the arrangement of their leaves in two opposite rows along the branchlets.

As regards hardiness they are certainly not fitted for the most inclement parts of the British Isles. They succeed best south and west of London, but the following species have for several years grown well at Kew: antarctica, betuloides, Dombeyi, obliqua and procera. These, it will be noticed are all South American; in fact, no success in the open air has been obtained with the Australasian kinds. The successful cultivation of New Zealand, Tasmanian and Australian species can only be accomplished in localities where the general run of New Zealand trees and shrubs and Himalayan rhododendrons such as Aucklandii and grande succeed.

They do not seem particular as to soil, but prefer more than any perhaps a good, deep, friable loam. But on the peaty soil at Knap Hill there used to be (perhaps is now) a quite good specimen of N. betuloides. I do not remember seeing any of them in gardens situated on chalk or lime that I have visited, but that is a matter on which I have no definite knowledge. Perhaps information could be supplied by some readers of THE GARDEN.

The best grown trees will probably be those raised from seed, but layers for possibly all, and cuttings for some, may be used. N. Dombeyi and N. procera we have struck quite easily from late summer cuttings, and N. betuloides and N. antarctica have taken root from layers; the former, however, is very slow.



ONE OF THE MOST PROMISING SOUTHERN BEECHES, N. OBLIQUA.

SOUTH AMERICAN SPECIES.

N. ANTARCTICA.—According to Loudon, this tree was first introduced to this country along with betuloides in 1830; it was also sent from Tierra del Fuego by Sir Joseph Hooker in 1843. Writing in his "Flora Antarctica," this famous botanist and traveller says that, along with betuloides, it principally composes the dense dark forests which cover the shores of the Straits of Magellan and the mountain slopes of Tierra del Fuego. N. antarctica reaches considerably higher altitudes than betuloides and ought, one would imagine, to be considerably hardier. The earliest introduced plants, nevertheless, did not survive, and Elwes and Henry at the time of publishing the third volume of their great work had only been able to discover in Great Britain a single tree, which was at Hafodunos in Denbighshire and was then 15ft. high. Mr. Elwes brought home seeds from Chile in 1902, from which a considerable number of plants were raised. These have succeeded very well up to the present time and some are now 15ft. to 25ft. high. N. antarctica is

Digitized by Google

deciduous, and although these trees have not the slender shape or stature of N. obliqua introduced at the same time, being more spreading and bushy in habit, they are still quite elegant. The leaves are ½in. to 1½ins. long and are set in two opposite rows on the downy branchlets not often more than ½in. apart; they are minutely round-toothed.

N. BETULOIDES.—First introduced from the south of South America in 1830 and afterwards by Sir Joseph Hooker in 1843, this charming evergreen tree is still comparatively rare—not so rare, however, as its companion tree, N. antarctica, was up to 1902. It has lived in the open air at Kew for the last twenty years and I have seen good specimens in the late Mr. Chambers' garden near Haslemere and in the Knap Hill Nursery. But it will never be so fine a tree in any of those places as it is in the south-western counties. No specimen of it in the British Isles, so far as I know, equals one in Lord Clinton's arboretum at Bicton in South Devon. I measured this in 1920 and it was over 50ft. high, about 40ft. in diameter, its trunk 9ft. in girth at 18ins. from the ground. The leaves are ½in. to 1in. long, ¼in. to ⅜in. wide, dark glossy green above, paler beneath, but not downy. They are set on the twigs ½in. apart and form masses of foliage, dense but not ungraceful. The leaf margins have rounded teeth and the young shoots are covered with fine down.

N. DOMBEYI.—For the first introduction of this fine tree we are indebted to Mr. F. R. S. Balfour of Dawyck, who imported seeds at the end of 1916. It is remarkable that so notable a tree should not have been introduced before, for, according to Mr. Elwes, it forms, along with N. obliqua, the chief timber supply of Chile. Near the Baths of Chillan he measured two trees, one 27ft., the other 22ft. in girth of trunk. But the seeds of these southern beeches seem to keep badly, or a large proportion of them are infertile. Mr. Elwes brought home seeds in 1902, but none of them germinated, and of the considerable quantity Mr. Balfour imported in 1916 only four grew. This is an evergreen tree, its leaves being ⅜in. to 1½ins. long, half as much wide, ovate to ovate-lanceolate in shape, pointed, finely and rather unevenly toothed. They are dark glossy green above, paler bright green beneath and specked with minute blackish glands on both surfaces, but more thickly beneath. The young shoots are clothed with very minute down. As a young tree it is very elegant. The young trees raised from Mr. Balfour's seeds are succeeding well and have not been affected adversely by any winter cold since 1917, although towards spring they sometimes lose a good proportion of their foliage and cease to be as strictly evergreen as they appear to be in their native country.

N. OBLIQUA.—At present this is the most promising of all the southern beeches in cultivation. It was originally introduced from Chile by William Lobb for Messrs. Veitch in 1840, but apparently none of that sending survives, and the best trees now in cultivation we owe to the late Mr. H. J. Elwes, who brought seeds home in 1902. One of several trees at Kew now twenty-two years old is 56ft. high, the stem 3ft. 2ins. in girth. They are slender in form, extremely elegant, and on the whole among the most attractive of all deciduous trees of their size and age. And apart from poplars there are not many hardy deciduous trees whose average annual growth exceeds 2½ft. It does not appear to be known how it was that trees of Lobb's introduction died out. If one had time to wade through the gardening periodicals from 1849 onwards, it might be possible to find out. Judging by the behaviour of existing trees they would appear to be quite hardy, but since 1902 we have had no frosts like those of February, 1895, or winters like that of 1860–61. Until we do, there must remain some uncertainty as to whether this beech can endure all that the English climate is capable of. Its leaves are 1½ins. to 3ins. long, about half as much wide, with irregular, triangular, pointed teeth on the margin. The young shoots are not downy. It flowers quite freely and develops the small three-sided nuts, but none of these, so far as I know, has proved fertile.

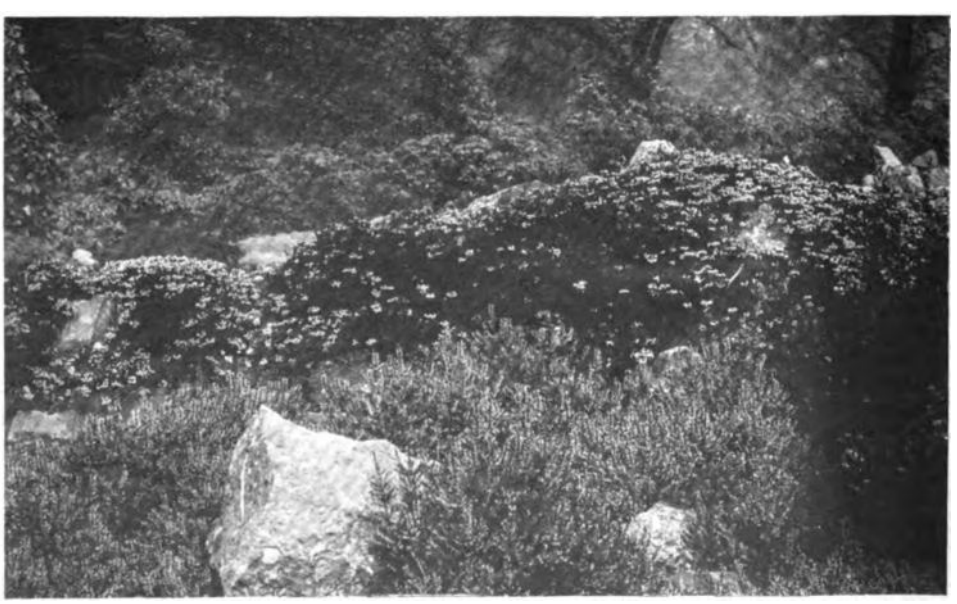
N. PROCERA.—This Chilean tree does not appear to have been introduced to this country before 1913, in which year seeds were sent to me by the Dendrological Society of France, of which I am a member. It has grown well, and during the eleven years it has been growing at Kew has not been in the least affected by cold. Naturally, it is a deciduous tree of large size. From the other Chilean beeches it is very distinct in the size and character of the leaves, the largest of which are up to 4ins. or 5ins. long and 1¾ins. wide, finely toothed. In general appearance they suggest the leaves of hornbeam or, still more, those of Alnus firma, having on each side the midrib fourteen to eighteen prominent parallel ribs. The young shoots are downy. Our young trees are of erect growth, rather stiff in habit, and unless their progress is interrupted by more cold than they like, promise to make fine trees. Cuttings put in in gentle heat in August have taken root readily.

(To be continued.)

SOME NOTABLE ERICACEOUS PLANTS

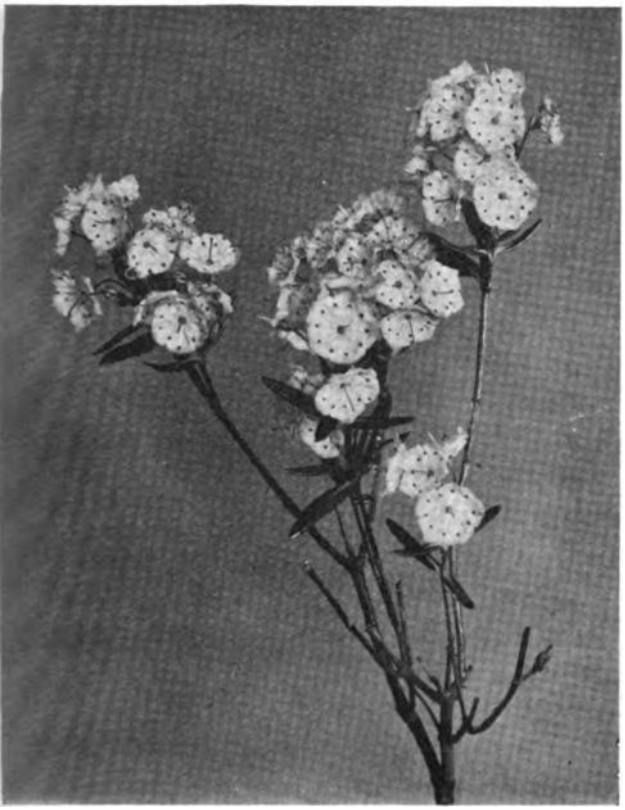
APART from the rhododendrons and heaths there is a number of allied shrubs which do not seem to be as well known as they deserve to be, plants often of the rarest charm and which are not in the least degree difficult in any medium lime-free loam. Most of these, it is true, like the latter to be on the cool side and they enjoy really old leaf-mould. But that these so-called peat plants need peat is a fallacy which has doubtless been instrumental in deterring many gardeners who do not possess that material from going in for them.

Here I can only deal with a select few, and none of the easier ones is more deserving of first mention than Bryanthus (Phyllodoce) empetriformis. This delightful little shrub will cover a couple of square feet or more with its semi-prostrate, heath-like foliage, and in spring and again in autumn it is singularly beautiful with its crop of bright rosy purple, pitcher-shaped flowers supported by stems and calyces in a vivid crimson. This species is the best and hardiest of its genus, and none is more worthy of fuller recognition. B. Breweri, not less charming, of much the same habit of growth and with very similar foliage, is not quite so hardy and it does not always flower with the freedom of the sister species. The flowers of this



THE BEAUTIFUL AND HARDY BRYANTHUS EMPETRIFORMIS WITH ITS CHARACTERISTIC ALMOST PROSTRATE HABIT AND ITS MASSES OF ROSY PURPLE BELLS.

Digitized by Google



ORNAMENTAL IN FLOWER AND FOLIAGE, KALMIA LATIFOLIA

Californian are borne in short racemes instead of singly as in empetriformis, and the rosy lilac corollas are not contracted at the mouth but spread wide open like little bells.

B. erectus, now called Phyllothamnus erectus by our masters, is a rare and choice shrublet which no lover of dwarf ericaceous plants should be without. It may be expensive, it may even be difficult to acquire at any price, but there are firms—all praise be to them—who stock this jewel and it is worth all they ask for it. B. erectus is said to be a hybrid between Rhodothamnus Chamæcistus and B. cœrulea (which I find is not nearly as blue as it is painted) and it presents itself as a sturdy bushling under a foot in height and well furnished with a bright glossy green, yew-like foliage. In spring the flowers appear in clusters at the tips of the branches, and these might be likened to those of some tiny azalea, the spread of the five-lobed corolla, which is a lovely shade of clear rose, being about half an inch. We find this precious treasure quite easy and good-tempered on a cool side in the heath garden, the soil being shaley loam enriched with a little leaf-mould.

Under similar conditions Bruckenthalia spiculifolia also prospers, making dense cushions of fine, heathy foliage. Above these arise the flowers in early summer, closely packed racemes of pale pink corollas, their wide-open mouths being suggestive of some calluna. I have seen this neat little heathy plant growing under conifers where the ground is often very dry, but it seems to need exposure to enable it to flower well. Kalmia glauca must also be included in this list, for it is a singularly pretty shrub, not often more than a foot in height, with narrow leaves of a deep lustrous green and almost white undersides. The flowers, which appear in late spring in terminal clusters, are about half an inch across, of the characteristic kalmia shape, and the colour is a pleasing full-toned rosy pink. Being naturally a bog plant (I have seen it flowering with its feet in shallow water in the Rockies), K. glauca has a right to insist on moisture being sufficient at all times, especially in spring, but it will be happy enough in a really cool mixture of leaf-mould and loam with a top-dressing of the former (or layer of sphagnum) over the roots in April.

Another dwarf North American of quality is Leucothoë (Andromeda) Davisiæ, the Benjamin of rather an exclusive race and perhaps the most beautiful. This, again, is by no means difficult if the simple demands of most of its genus are observed. We grow it in a partly shaded woodland bed allotted to such things, the root run consisting largely of leaf-mould, mainly of the pine wood variety. L. Davisiæ is a shrub of 1ft. or 2ft., rather rigid in habit, with leathery, dark green leaves and jaunty cockades of flower racemes, the corollas being white and nodding.

In the same grouping, but where it gets full sun, is Leiophyllum buxifolium, the sand myrtle of the Eastern States of North America. Sweet-tempered as it is and charming at all seasons, this pretty bushling is not seen as often as it might be. It prospers in any coolish loam and when its small, box-like foliage, dark green and highly burnished, is studded with its innumerable crimson flower-buds it is even more delightful than when the whole plant becomes a rounded mass of silvery white, pink-tipped blossoms scintillating like crystal in the sunshine of May.

L. buxifolium has a cousinly relationship with the ledums, but we have not yet managed to make much of a success with these, and the cassiopes and Epigæa repens must also be numbered among the willing but weak nostalgics which refuse to be comforted. While we have not yet abandoned all hope of satisfying these fascinating wildings, there is no gainsaying that what they usually crave for is not so much their native soil as their native air. They yearn for the spartan winters and mosquitoed summers of their far-off motherland, the silent North, and for these our kindliest substitutes are but a poor makeshift.

Vaccinum glauco-album is an uncommon and distinctive member of a numerous and conflicting clan, a shrub of rather more than 2ft. which at first glance might be taken to be Gaultheria Shallon. But it is smaller in all its parts than the latter, the undersides of its leaves are a vivid bluish white, and this colour also pervades the flower-bracts and the fruit. A most desirable shrub for associating with heaths and kindred subjects. Here it has for stable companions some of the more easily grown gaultherias, such as G. Veitchiana and the closely allied Hookeriana. G. Forrestii and pyroloides cuneata, Used as a carpeter about such subjects

THE HANDSOME WINTER GREEN, GAULTHERIA PROCUMBENS.

Digitized by Google

as the above and others, G. tricophylla is very precious and, once it is established, by no means backward in yielding its intensely blue fruits, which seem so enormous for so small and slender a plant. As for G. procumbens, it grows freely almost anywhere in the woodland, and familiarity will never breed contempt for its bright red winter berries. G. nummularioides also prospers abundantly, draping a bank with its long, prostrate stems, closely set with their pairs of dark green, rusty leaves and overlapping one another in a dense tuft like a greatly magnified spleenwort fern. Though this Himalayan flowers well, hiding its inconspicuous corollas underneath the leaves as if it were conscious of their feebleness and never suffering from frost, it does not ripen its fruit with us. A. T. JOHNSON.

DECEMBER AT VINCENT SQUARE

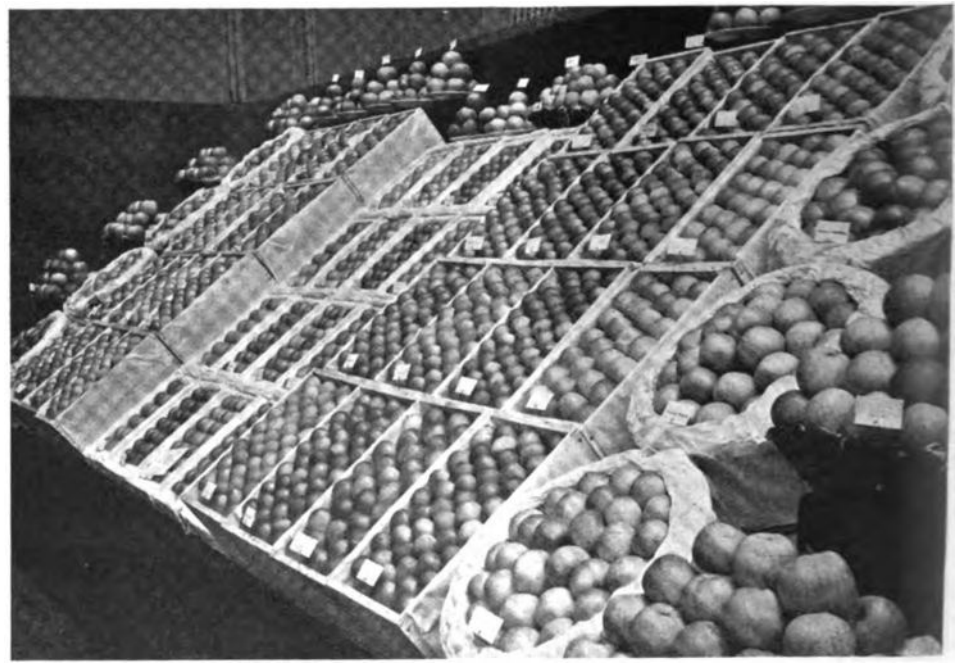
THE end of the season is gradually becoming more apparent at the fortnightly shows of the Royal Horticultural Society, and although there were many exhibits at the second last meeting of the year, held on December 2nd, there were few floral exhibits to lend brightness to the hall. True, there were one or two fine shows of chrysanthemums for December, and the orchids were good, but one had to rely chiefly on the work of the artists for colour effects. There was also a distinct falling off in the attendance, due, no doubt, to the miserable weather conditions. Fruit was represented by small but well arranged collections from Messrs. Bunyard and Co., H. Hemsley and the Hollesley Bay Labour Colony. The main exhibits were those from landscape architects, artists and sundriesmen, and these always evoke a considerable amount of interest, especially if any new and, to all intents and purposes, useful article makes its first appearance before the public. Gardeners, although often criticised as a conservative body, are sometimes eager to have a trial of any new appliance when it comes along, and if it meets with their requirements the extended use and ultimate success of the article is assured. One particular exhibit was of interest, that of Mr. J. Jardine with his Médoc and Guienne secateurs. Gardeners are well aware of how many patterns of this useful tool are on the market, and also how many of these are totally inferior. These "Guienne" secateurs, however, although expensive, apparently have everything in their favour and merit a trial.

One of the main exhibits at the Show was that of Mr. George Reuthe, Keston, Kent, who had a very fine collection of conifers, almost every genus being represented by one or more species and varieties. Within recent years, conifers have come to occupy a most important place in the world of horticulture. Their value from a timber and forestry standpoint has long been recognised; but with recent explorations all over the world and the discoveries of many species new to science, and the interbreeding of these species by the enthusiast, there has arisen a multiplicity of new varieties and forms eminently suited by their shape and size to be classed as inhabitants of any ordinary garden. The rock gardener knows their value in his alpine patch, while the shelter given by others, suitably planted, to plants of less hardy constitution is unrivalled. They are admirable as shelter belts, wind screens and hedges. Mr. Reuthe's collection enabled one to see the enormous progress which has been made during this present century. It was a representative world collection—from China and Japan to the western seaboard of America, and from New Zealand to northern Canada. The pines were well represented by such species as aristata, Balfouriana, contorta and flexilis—the latter a most graceful species; while the spruces or piceas, so often confused with abies, were shown to advantage by such forms as aurantiaca, koyamia, Morinda and Engelmanni. Perhaps the most ornamental and decorative of the cultivated conifers are the firs, especially valued because of the white under-surfaces of their leaves. Their decorative qualities were admirably shown by species such as balsamea, numidica, concolor and Webbiana.

Those selected as suitable for pot culture and decorative plants for the house included Widdringtonia Schwartzii—a most graceful plant—Picea Vilmorini, species of podocarpus and abies. Formerly, the one and only decorative conifer grown in the house was Araucaria excelsa; but with such a selection one's slightest whim can be satisfied. The gathering together of a collection such as Mr. Reuthe staged involves much labour and skill, time and patience, and we feel sure that his efforts will be well rewarded by the patronage he deserves at the hands of the horticultural public.

A touch of colour was lent to the drab and mournful appearance of the hall by Major Pam's well arranged exhibit of begonias. There were well grown seedlings in shades of pink, salmon and white, all tastefully arranged. The flowers were carried well on their stems and were shown off to distinct advantage by the always delightful green tints of the leaves. The plants did not show any ill effects of frost or other evils attendant on our clime which befall so many other raisers of this plant, and the fact that Major Pain braved the elements in these dull December days with his exhibit gave pleasure to many on Tuesday last. Begonias, more than ever, are being largely employed for bedding purposes, and as such give excellent results, far superior to the old days, when they were treated as stove plants. They also lend themselves for conservatory and other decorative work, being especially valuable owing to their long flowering season, which lasts from mid-July till the advent of frost. They are of easy culture and, in fact, in every way they merit the attention of the amateur. Major Pam's collection should do much to arouse that interest in this plant which is only now beginning to assume its rightful position among the many others of its kind.

The Hollesley Bay Labour Colony showed a most excellent selection of apples and pears packed for market. Although the size in some cases was not large, yet the colour was good and the grading beautifully carried out. Many of the common market varieties were to be seen, among them very fine examples of Bramley's Seedling. The packing was equal to that of any foreign apples that we have seen. The exhibit reflected great credit on Mr. H. Barton, the superintendent.



THE EXCELLENT EXHIBIT OF APPLES BY THE HOLLESLEY BAY LABOUR COLONY.

Other exhibits were as follows:

Apples.—Messrs. Bunyard and Co., Hollesley Bay Labour Colony, H. Hemsley.

Begonias.—Major Albert Pam.

Cacti.—Mr. Sidney Smith.

Carnations.—Messrs. Allwood Brothers, Stuart Low and Co., C. Engelmann.

Chrysanthemums.—Messrs. Keith Luxford, Cragg, Harrison and Cragg, A. G. Vinten, Mr. Arthur Young.

Conifers.—G. Reuthe.

Cyclamens.—Messrs. Stuart Low and Co., Caledonian Strain Floriculturists, Sutterbridge, Luton.

Grapes.—The Hon. Vicary Gibbs.

Hardy Plants.—William Wells, jun.

Orchids.—Messrs. Cypher, Limited, Sanders, G. F. Moore, London Gardens, Florists, Stuart Low and Co., H. J. Pitt, A. J. Hollington, Sir Arthur Watson, Messrs. Cowan and Co., Robert Paterson.

Shrubs.—H. Hemsley.

Topiary.—J. Klinkert.

Digitized by Google

Violets.—J. J. Kettle, Baldwin Pinney.
Landscape.—Percy S. Cane, Jean Graef (mistletoe grafts).
Artists.—Edith A. Andrews, Maud G. Angell, Marion Broom, Edith Fisher, Agnes Foreman, Margaret Linnett, Sophia Miller, Mrs. Henry Spenser, Claridge Turner, Winifred Walker, Ellen Warrington, Juliet Williams, Alice E. Wilkinson.
Horticultural Sundries, Tools, etc.—House and Garden Sundries Company, Limited, Messrs. Walkers (fruit tree protectors), Chase Continuous Cloche Company (alpine plant protectors), E. R. Buggé (sprays and powders), J. Jardine (Médoc and Guienne secateurs), Thomas Gunn, Limited (tools), Miss Alice Baker, John Pinches (Acme labels), Ashtead Potters, Limited (china bowls), H. J. G. Wood (plant supports), Radium Fertilizer Company (fertilisers), Carter and Williams (labels and insecticides), Abbott Brothers (bird sanctuaries and shelters), A. Everitt (gardening gloves), S. E. Wilson (garden lights).
Jams, etc.—Miss Hilda Sewell, Moyleen Confections, Limited, Pickering Cottage Preserves (bottled fruit).

NEW AND RARE PLANTS.

AWARDS OF MERIT.

CARNATION JANET.—This is a perpetual-flowering variety with well formed blooms of a deep carmine tinged with blue in colour. These are borne on stiff, wiry, tall and erect stems, carrying the flowers well. It has a slight fragrance. Shown by Mr. C. Engelmann.

CARNATION DORIS COX.—A perpetual-flowering variety which did not in any way appeal to us. The blooms are carried well, but the colour is in no way attractive. It is a washed-out shade of lilac-mauve. Shown by Mr. George Carpenter.

RHAMNUS ERYTHROXYLON.—This species is a representative from eastern Siberia and Mongolia, and, from the fruiting sprays exhibited, appears closely allied to R. cathartica. It is a hardy deciduous shrub, and at this time of the year bears clusters of black fruits about ¼in. across. In appearance it is handsome, though somewhat funereal. Shown by the Hon. Vicary Gibbs.

ORCHIDS.

Cypripediums formed the chief feature at this meeting, the day having previously been selected for a special display of the autumn-flowering kinds. A gold medal was awarded to G. F. Moore, Esq., Chardward, Bourton-on-the-Water, Glos., for a group of outstanding merit, while a silver-gilt Lindley medal was awarded to his gardener, Mr. W. H. Page, for the excellent cultivation of all the plants. Another attractive group was staged by Robert Paterson, Esq., Cathcart, Glasgow, who received a silver-gilt medal for a choice selection, a bronze Lindley medal being awarded to his gardener, Mr. Merry.

CERTIFICATED ORCHIDS.

BRASSO-CATTLEYA BRITISH QUEEN VAR. SPLENDENS (B.-C. Dibyano-Mendelii × C. Lord Rothschild).—An immense flower of its kind, of rose pink colour, the expansive labellum prettily fringed at the margin, of rosy mauve colour on the front and side lobes, the throat lemon yellow. From Messrs. Cowan and Co. First-class certificate.

CYPRIPEDIUM CAPPAMAGNA VAR. FRED SANDER (Cardinal Mercier × Nubia).—Flower well above the average size, the broadly developed dorsal sepal heavily flushed with deep purple colour, the petals and labellum well proportioned and tinged with red-brown. From Messrs. Sanders. First-class certificate.

CYPRIPEDIUM CRUSADER, WESTONBIRT VAR. (Lucifer × Julian).—Probably the best hybrid yet seen combining size and colour. The large dorsal sepal orbicular in shape, almost covered with crimson colour, the upper border being white; petals and labellum yellowish, heavily tinged with mahogany colour. From Lieutenant-Colonel Sir George Holford, K.C.V.O., Westonbirt, Tetbury, Glos. First-class certificate.

CYPRIPEDIUM DORIS STANTON (Goliath × Pyramus magnificum).—One of the largest of hybrids in the genus, the dorsal sepal flushed with light rose, the upper part white, the broad petals and labellum tinged with dark purple. From G. F. Moore, Esq., Chardwar, Bourton-on-the-Water, Glos. First-class certificate.

ODONTONIA ALEXANDRA (Odontonia Merope × Odontoglossum Crethus).—A further step in the production of a warm-growing Odontoglossum, suitable for the United States of America, and produced by the inclusion of the genus Miltonia in the parentage. Sepals and petals blotched and spotted with crimson-purple, the widely formed labellum whitish, blotched with dark red at the base and with a yellow crest. From Messrs. Charlesworth and Co. Award of merit.

ODONTONIA OLIVIA VAR. PRINCESS (Miltonia Bleuana × Odontoglossum triumphans).—An improvement on the original form of this bigeneric hybrid; the segments of golden colour, blotched with red brown. From Messrs. Charlesworth and Co. Award of merit.

CYPRIPEDIUM OUR PRINCE (Goliath × Tommy Curte).—A large flower of bold construction, carrying forward the well known attractive features of both parents. From Robert Paterson, Esq., Cathcart, Glasgow. Award of merit.

CYPRIPEDIUM MRS. STEPHEN ANDERSON VAR. BISEPALUM (Bourtonense × Christopher). The chief feature of this large flower is the unusually developed ventral, or lower, sepal, which closely resembles the dorsal, or upper, sepal, hence the varietal name. Of light greenish yellow colour, the sepals margined with a white band. From G. F. Moore, Esq., Chardwar, Glos. Award of merit.

NEW CHRYSANTHEMUMS.

The following novelties were submitted to the Floral Committee of the National Chrysanthemum Society on December 1st, when awards were made.

JOHN HOWE.—A large single of attractive shape with slightly reflexed tips to the florets. There is a broad zone of pale golden colour which towards the tips is heavily stippled with bright crimson. Shown by Messrs. Keith Luxford and Co.

MRS. E. C. KINNS.—This is a sport from the well known Baldock's Crimson, but is rather a more graceful bloom. The colour effect is bright orange. Although not a market flower it would be of use, on account of its colouring, in gardens. Shown by Mr. E. C. Kinns.

SUNSHINE WILCOX.—A well grown plant about 4ft. high, and several vases of this sport from Miss Wilcox were shown. The golden bronze Miss Wilcox has been sent in large quantities to Covent Garden Market during the past week or so. Both sorts are grown in graceful sprays of small flowers with narrow florets. Sunshine Wilcox is a very bright golden yellow. First-class certificate. Shown by Mr. Arthur Young.

WALTER HOWE.—A most brilliant single fully 6ins. across. The broad flat florets are in two rows and of a rich velvety crimson colour. First-class certificate. Shown by Messrs. Keith Luxford and Co.

PROPERTY DAMAGED BY ROAD IMPROVEMENTS

GARDEN WAYSIDE PROPERTIES.

OWNERS and occupiers of garden wayside properties often find that they are sufferers by reason of the activities of their local authorities in attempting to cope with the requirements of modern traffic. Two examples are to be found in connection with tar spraying work or road drainage, the results of which frequently cause damage and loss to properties bordering the highway. The unfortunate owner or occupier who is adversely affected in this way is generally perplexed when considering whether he has any right to be compensated for any injury imposed upon him by public work of such a character.

A CASE OF TAR SPRAYING.

Quite recently there was an action in the High Court against a District Council which had allowed its road surface water, charged with tar acids, to drain into two watercress beds belonging to the plaintiff, and through these beds to the streams beyond. The result was that the watercress beds were destroyed. The Council had tar-sprayed the road adjoining the property, but the tar was broken up some months after, during a spell of frost, and the surface water from the road soon contained sufficient tar acid to cause the injury described. The Council attempted to protect itself by its statutory powers under the Public Health Act, 1875, which, no doubt, allowed it to tar-spray the road, but not to discharge the road water so affected by the tar acid into the plaintiff's watercress beds to do damage there; unless, at least, the damage which resulted was not, practically, avoidable, in the exercise of the Council's statutory authority. The Council did not try to prove that the road water could not be taken to the stream, which was close by, without going through the plaintiff's property. But while it was entitled to the right to drain off the road water in this way, it had no such right to let the water drain into the watercress beds in the state it was in, nor, for that matter, into the stream itself, in its noxious condition. The Council failed to show that the result of what it had done was a necessary consequence of the discharge of its statutory power, and judgment was given for the plaintiff.

A DRAINAGE CASE.

It frequently happens that the property or premises of rural owners and occupiers, and sometimes those in urban centres, are injured by floods, or an abnormal rainfall, which the defective or insufficient drains or sewers of the local authority are unable to carry off quickly enough to avoid damage and loss arising. This question, too, has been lately considered, and by the Court of Appeal. A local authority, as it was then observed, would be liable in an action for damages, notwithstanding its statutory powers, whenever it was proved that those powers were exercised negligently in these matters.

A STATUTORY REMEDY.

When, however, there has been no such negligence by a local authority, in such or similar cases, but, nevertheless, damage has resulted from its proper discharge of its public work of this nature, the remedy of any person who suffers damage is not by an action, but by recourse to Section 308 of the Public Health Act, 1875, which provides that full compensation shall be made to any person, not in default, by the local authority exercising such powers for any damage which may have been sustained by reason of the exercise of any of the powers of the Act.

A LAWYER.

Digitized by Google

MADRE DE LORO

FROM the crest of the ridge we look back down the tortuous mountain valley up which we have toiled, with its great rock masses, its patches of trees and bushes, and little terraced fields poised here and there on the steep slopes. Turning again, a glorious view lies in front of us. The ridge on which we stand sweeps away to the left in a semi-circle, varying from 3,000ft. to 4,000ft. in height, and enclosing a broad basin some miles in diameter, filled with dense unbroken forest—a finer forest scene than can be found anywhere else on the Canary Islands, for Gomera surpasses the other islands in the extent and luxuriance of its woods. Under the guidance of our Canario friend, we plunge downward into the cool shade. The composition of the forest is very interesting, for all the species which grow here are unfamiliar to us, at least as forest trees. Four members of the laurel family are conspicuous—Viñatico (Persea indica), Loro (Laurus canariensis), Barbusano (Appolonias canariensis) and Til (Ocotea fœtens). The first two of these are particularly striking, forming glorious lofty trunks. The beautiful davallia (D. canariensis) and the common polypody of our English rocks (P. vulgare) cling to their trunks, and a species of sempervivum (S. amnium) perches high up on the moss-grown boles and makes yellow splashes of colour, outshone by the scarlet fallen leaves of the viñatico. Among the other native trees we see the mocan (Visnea maconera), the hija, which we call Portugal laurel (Prunus lusitanicus), a fine large-leaved holly Acebiño (Ilex canariensis), Palo Blanco (Notelæa excelsa), Aderno (Heberdenia excelsa), marmolan (Pleiomerus canariensis) and several ericaceæ, madroño (Arbutus canariensis), Myrica Faya, Brezo (Erica arborea). The last named, the tree heather, perhaps interests us most, for we are rather proud of having at home a bush of it 10ft. high, which covers itself in early spring with fragrant grey-white blossom. But here it forms groves, 50ft. in height. I try to get my arms round one of the trunks, but my hands do not meet, for it is 7ft. in circumference.

A diversion occurs. Our guide steps out on a projecting spur, surveys the valley below, puts his fingers to his lips, and gives a long complicated whistle. We listen with attention, for this is the famous whistling language of Gomera. The sound echoes from the woods opposite, is repeated by more distant hills, and dies away. The whistler listens, shakes his head, and calls again. Whee, whee, whee—whee, whee, whe, whee-e-e-e, floats out over the forest. No answer. We resume our march, and half a mile farther on the shrill call is given again. This time a faint clear answer comes up from far below. "Good," says our guide; "I was telling Juan to bring a cheese to the luncheon-place," he explains. Presently we debouch into an open glade, where a sight greets us most rare in the Canaries—a broad, cool, rippling stream. The hot sunlight dances on the shallows, and the sides are lined with ferns of many kinds. "Here we eat," says Don Pedro. Bread and wine, sardines and gofio, appear from mysterious saddle-bags. The gofio is kneaded with water from the stream, and lunch is ready. While we eat, a venerable man strides up, his long "lanca" in one hand, in the other a fresh cheese wrapped in a clean napkin. "Ah, Juan," says our guide, "you have come."

After lunch we are called aside to see one of the curiosities of the forest. A great laurel ("bay," we would call it) rises solitary, and on its trunk, a few feet up, is a curious outgrowth forming a ring round the stem—a series of almost forked growths, neither roots nor branches. They are soft and velvety to the touch, and remind one of a deer's horns while still in the velvet. They come away easily from the stem, and we break one across. The section shows a uniform green watery tissue, like the stem of a succulent plant. It has the fragrant scent of laurel, and is clearly portions of the tree, not a fungus parasite or anything of that sort. It is a puzzle, and we appeal to our guide for information. "Madre de Loro" (Mother of Laurel), says he. What is it? Frankly I do not know, nor have I discovered any reference to it in the books to which I have had access. No doubt the men of science have worked it all out—probably those industrious Germans to whom we owe most of our knowledge of the plants of the Canaries. But I am not sure that I do not prefer leaving it there, a mystery among those beautiful forests.

R. LLOYD PRAEGER.

CORRESPONDENCE

HARDY PERENNIALS FOR SUB-TROPICAL GARDENS.

SIR,—In his interesting paper on this subject (page 792), Mr. Canning-Wright bestows well-merited praise on the pampas grass; but I cannot agree in his opinion that "nothing excels it." I submit that Arundo conspicua is its superior in several respects. Its long wands bear aloft their heavy silky tassels at mid-summer, and at the present time (November 21st), these are as fresh as ever; whereas the pampas grass does not flower until autumn (in this late untoward season none appeared until October). The arching stems of A. conspicua are far more slender than those of the pampas grass, but they are of a consistency enabling them to withstand any amount of buffeting and to carry the flowering heads untarnished well over Christmas.—HERBERT MAXWELL, *Monreith.*

HYACINTHS IN ORCHID POTS.

SIR,—I herewith enclose a photograph of hyacinths grown by me in orchid pots. They are easily grown in this way, and are quite a novelty. I hope the illustration will prove of interest to the many readers of your valuable paper.—FRANK S. COOPER.

AN ATTRACTIVE WAY OF GROWING HYACINTHS

COLD HOUSE RHODODENDRONS.

SIR,—While quite agreeing with Mr. Cox's article on this subject and knowing how right he is in advocating the desirability of using derelict (or new!) houses for the cultivation of rhododendrons, I should suggest to those proposing to adapt houses under the conditions he advocates, to try a better sort of plant than he puts forward, viz., the sweet scented ones. I would suggest R. Edgeworthii and its hybrids, fragrantissimum, Sesternanum, Lady A. Fitzwilliam, Princess Alice, as well as R. Gibsonii and R. ciliicalyx. If these are planted in a house in good soil they will layer themselves in a few years and their fragrance can be enjoyed yards away, or in the case of the glasshouse adjoining the main building, it will permeate the whole structure, the most delicious of all garden perfumes. These are all semi-dwarf plants, for a larger building I would propose R. Nuttallii (the Queen of Rhodos), R. Dalhousiæ, R. grande argenteum, of course R. Aucklandii (Griffithianum), R. Victorianum, any of Gill's Aucklandii hybrids, "Gill's Triumph," "Ernest Gill," etc.; R. Boothi, and for smaller growing shrubs, R. fastigiatum and R. Augustinii. None of the

Digitized by Google

latter has much scent. I would also recommend Camellia reticulata and Clethra arborea, but perhaps I am now copying the Temperate House at Kew, and not a bad example either! Luckily in these Western districts nearly all the above mentioned shrubs will do quite well out of doors, but I should rather doubt R. Nuttallii, though at Torquay it seems quite at home. We grow most of the rhododendrons here, but so far I have found nothing from China to equal the Sikkim plants, though our sport of R. oreotrephes is quite a sight to see.—AUSTIN MACKENZIE, *Argyllshire*.

PRUNUS SUBHIRTELLA (VAR. AUTUMNALIS).

SIR,—This Japanese rosebud cherry has been in full blossom here through November. The pink and white blossoms are borne thickly on last year's wood and have withstood the sharp spell of frost we have just experienced. The tree is planted among rhododendrons in a bed facing east, in deep loam enriched with cow dung and peat. On this tree the blossom and leaf showed together. On another tree planted on a lawn on the south side of the house (shallow loam on shale) the growth has been very small. All the leaves fell in October, and although the old wood is studded with blossom buds they will be a month behind the other in opening. The trees seem to be perfectly hardy.—KNILL, *Barnstaple*.

MORE ABOUT PERSEPHONE.

SIR,—If it is not too late—I have been busy getting the garden ready for a frost which did not arrive—I shall be glad to answer Mr. Jacob's query regarding the quest of Persephone, in the number dated September 6th, page 623. She might be called the originator of the poet's, or perhaps, of the polyanthus narcissus. According to Homer, with her attendant nymphs,

> "Fair Proserpine consumed the fleeting hours
> In pleasing sports, and plucked the gaudy flowers,
> Around them wide the flamy crocus glows,
> Through leaves of verdure blooms the opening rose;
> The hyacinth declines his fragrant head,
> And purple violets deck th'enamelled mead.
> The fair narcissus far above the rest,
> By magic formed, in beauty rose confessed.
> So Jove, t'ensnare the virgin's thoughtless mind,
> And please the ruler of the shades, designed.
> He caused it from the opening earth to rise,
> Sweet to the scent, alluring to the eyes.
> Never did mortal or celestial power,
> Behold such vivid tints adorn a flower,
> From the deep root an hundred branches sprung
> And to the winds ambrosial odours flung;
> Which, lightly wafted on the wings of air
> The gladdened earth and Heaven's circuit share."
>
> *Hymn to Demeter* (*Ceres*).

Then follow the yawning of the ground as she approaches the marvel, and the rape of the maid, Persephone or Proserpine.

There is no doubt that narcissi were commonly worn in chaplets. Theophrastus mentions them, and Sophocles' chorus in "Œdipus at Colonnus," explains that "ever, day by day, the clusters of the fair narcissus bloom, quickened by the dew from heaven, the crown from days of old for mighty goddesses; the crocus, too, with gleam of gold."

This juxtapusition of narcissus and crocus seems to be more than accidental. The crocus was a favourite subject for design among the ancient Cretans, perhaps on account of its colour, suggesting the sun; one wonders if, for the same reason, the yellow narcissi were not the ones which grew for Proserpine; but what connection existed between the narcissus, whether poet's or tazetta, and the maid, I cannot discover. Possibly it was its heavy scent and its pallid, deathlike hue, like the colourless shades in Pluto's realm, or the scarlet-rimmed cup may have symbolised the sun itself, or the female principle, by its circle. If ever I get to London again I am going to search the British Museum for that wreath!

There is a note in the Encyclopædia Britannica (ninth edition) in the article on Eleusinia, stating that a procession escorted "a basket containing pomegrantes and poppy seed (the latter representing the stupefying power, Napkiooog, under whose influence the maiden, Persephone, was stolen away)," which causes me to wonder if in the most ancient days narcissus did not mean "Poppy," but laymen wandering in philological pathways are apt to go astray. At any rate, poppies were the especial flower devoted to Demeter, the mother of Persephone, whom Theocritus' harvesting shepherd hoped to see smile upon him with poppies and corn in her two hands. They were constantly woven into her coronals. She was said to have discovered them, and the narcotising properties of their juice at Ægialea, afterwards known as Mecone, "poppy-town" (whence Meconopsis, I suppose?), still slumbering under or amid poppy fields.—HELEN INGERSOLL, *N. Y.*

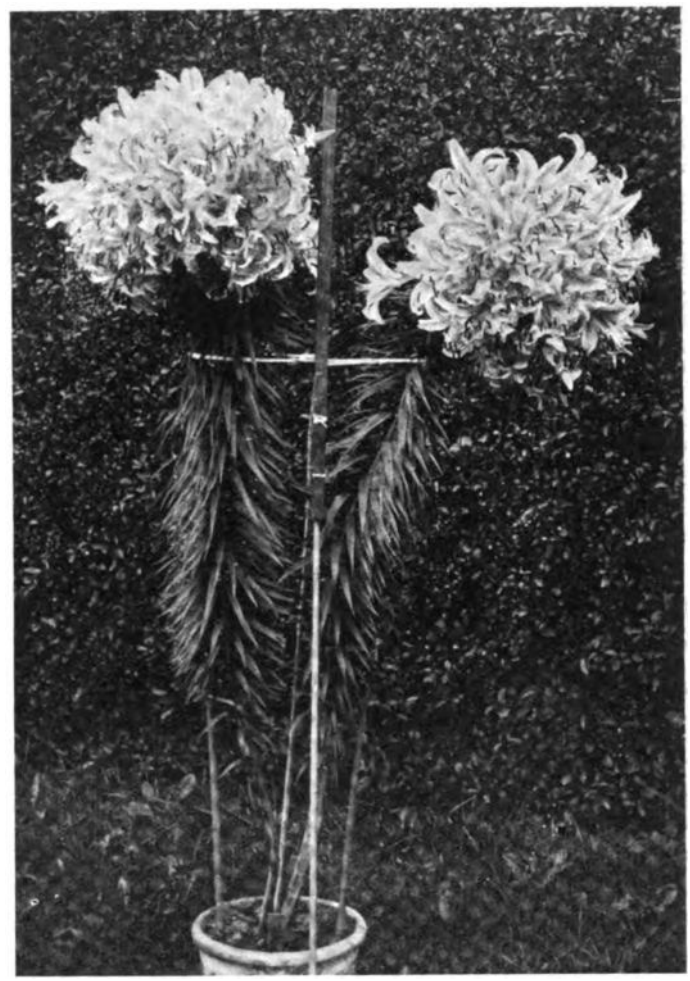
COLOURS IN HYDRANGEAS.

SIR,—In regard to the answer to "W. C.," Guernsey, regarding preventing hydrangeas turning blue, on page 611. Experimental work done by the New Jersey Agricultural Experiment Station at New Brunswick, N.J., U.S.A., proved conclusively that the varieties of H. hortensis commonly grown in our greenhouses for spring forcing will be blue or pink depending upon whether the soil is sweet or sour. Many varieties were tested. My recollection is that the white varieties did not vary with the soil, but blue-flowered varieties were easily turned pink by growing in soil to which enough lime had been added to give it an alkaline reaction. Pink varieties bore blue flowers when grown in soil with an acid reaction.—PARKER T. BARNES, *Harrisburg, Penn, U.S.A.*

LILIUM AURATUM.

SIR,—Having read the recent correspondence with reference to the record number of blooms upon a Lilium auratum, I enclose herewith a photograph of one grown by me last summer.

The bulb was one of a number obtained for me by a friend from Messrs. Prothero and Morris, and the total number of blooms was 175, one stem carrying ninety-six and the other stem seventy-nine. The bulb was a very large one and each of the two fasciated stems had a circumference of about 8ins.



LILIUM AURATUM, A RECORD NUMBER OF FLOWERS.

directly beneath the blooms. All the blooms opened within a couple of days and were counted just previous to opening, a large spot of whiting being put on each bud with a camel-hair brush as it was counted, to ensure against its being included twice.

The individual blooms were 5ins. to 6ins. across by about 4ins. deep. Many people came to see it, including Messrs. Treseder of Cardiff.—W. J. GUNSTONE.

NERINE MRS. W. R. LYSAGHT.

SIR,—I was interested in the picture and notes on this new nerine in your issue of November 15th. I understand from what Mr. Briscoe writes that the two plants illustrated were seedlings from the same cross, and were absolutely identical. This last mentioned occurrence is, I should think, very unusual. For though I have been raising nerines for seventeen years and have now no fewer than 257 distinct seedling stocks of my own raising, I fail to recollect any case in which there has not been some small varying characteristic. That is to say, no two have been *exactly* alike. Why is the nerine not more grown? There is no flower to compare with it for colour and brilliancy through the dull autumn days.—F. HERBERT CHAPMAN, *Rye*.

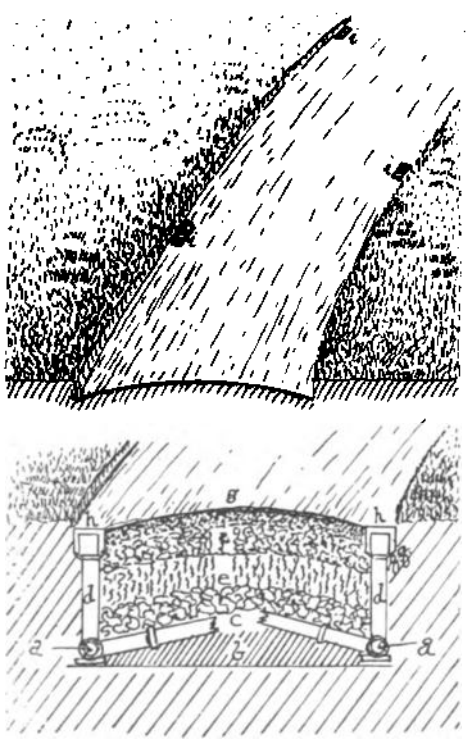
SIMPLE GARDENING

VENTILATION OF GREENHOUSES AND HEAT REGULATION.

DURING the winter months a great deal of pleasure is obtained through attention to greenhouse plants individually, and also in masses of plants arranged for effect in these structures. We must remember, however, that all the specimens, unlike those in the rockery and open border, are dependent upon our personal care for air, heat and moisture. The manipulation of the ventilators should be well studied and, daily, the weather conditions. In some nurseries, for the benefit of certain plants, a few houses are almost hermetically sealed, but the attendants are always close by to regulate the internal heat and moisture. The amateur's plant house is a different structure; it contains growing plants and others approaching the flowering stage or in full bloom. Air is required every day, but there should never be any cold draughts. The sun rises late and no harm will be done if it shines on the house for one hour or so before the ventilators are opened a little. Take note of the wind more than of the sun; a cold draught will prove harmful and this should be guarded against. Artificial heat should be lessened as the sun gains power and a little more moisture added. Usually, this is obtained in sufficient quantity from the ordinary watering of the plants. Damping of floors and paths, sometimes necessary in the summer, is not required now, nor till the spring.

MAKING NEW GARDEN PATHS.

There is neither economy nor satisfaction in the construction of garden paths unless the work is well done. It would be much better to confine the work, during one season, to the making of one path well, rather than to two, if the work in connection with them cannot be thorough. Of course, I am now referring to permanent paths made in old, as well as new, gardens. First, take due note of the watercourses after rains, and prepare accordingly to lay down sound drainage with good outlets. In some gardens, according to situation and soils, drain pipes are not required, only good open material for the base. In others, a complete system of drainage by pipes is essential. This we will briefly refer to now. One main drain will answer in some cases; two are necessary in others. The latter, shown in the accompanying sketches at *a*, *a*, with connecting drains from surface gratings and down-pipes at *b*, *c*, *c* and *h*, *h*. The base, at *b*, is quite firm ground, on the pipes, to form a general base, is rough material, shown at *e*, then finer at *f* and, finally, the surface layer at *g*. Gratings should be placed as shown at *i*, *i*, *i*. The water from the slightly rounded surface of the path will pass to the underground pipes as shown below. For main paths, where wheeling or carting of produce or soils pass over them the paths should be 1ft. deep in material; in the case of ordinary paths 7ins. will be sufficient without underground pipes. Broken bricks, clinkers and gravel are all suitable.



MAKING NEW ASPARAGUS BEDS.

Only in a few cases is it wise to leave the work of forming new beds to the date of planting—in March or April. The exceptions are those relating to beds in light, naturally well drained ground. The medium and heavy loams are all the better for full exposure to the air, rains and frost for several weeks prior to planting. Cultivators will be able to decide now what should be done. It may be advisable to have raised beds in one instance, and to plant on the level ground in others. In the former case the necessary raising of the beds should be done together with the work in general. In clayey soils two rows of plants in each bed will be enough and three rows where the soil is of a more porous nature. Allow a space of 18ins. between the rows and a 1ft. margin on both sides of the bed, the alley being 18ins. wide. Where the rows of plants are on the level ground the same distance should be allowed between the rows, and between every fourth and fifth row an alley 2ft. wide. Of course, readers know quite well that the asparagus plant is deep rooting and requires a well broken soil in which to grow. Only in exceptional cases should any drainage material be put in, as the neatly raised beds will be sufficient. On gentle slopes the beds should be formed east to west, if the slope is to the south, to husband the rains, but on quite level ground they should be north and south to ensure the maximum amount of sunshine reaching the plants.

PROPAGATING CHRYSANTHEMUMS.

Early in December the first batch of cuttings should be inserted. These must be cuttings of the naturally late-flowering sorts, those of Mrs. Gilbert Drabble, William Rigby, Majestic, Norman,

Chittenden and so on. Of course, the cuttings should not be subjected to any artificial heat beyond that maintained in a greenhouse where frost only is excluded. I do not use any heat except that afforded by the glass of a house used in summer for tomatoes. In these circumstances the cuttings do not root under five weeks, but they are sturdy. A good compost consists of loam two parts, leaf-soil one part and old mortar rubble one part. The cuttings should be inserted singly in small pots and watered before they are placed in the propagating frame. During the time that the cuttings are in the frame very little water will be needed and no shading. The glass of the frame is wiped dry every morning and evening, and care is taken to avoid loss through leaf or stem damping. If the leaves droop a little, sometimes a fine spray of water early in the day will do good. On no account should the soil be kept in a sodden state. At *a* the old plant pot is shown; at *b* a stem shoot, the wrong one for a cutting; at *c*, *c*, *c*, sucker shoots, the right ones. The weakly cutting, *d*, is unsuitable, the one at *e* is a good specimen. The right way to prepare a cutting is shown at *f*, and it is ready for insertion at *g*. In the small cutting pot, *h*, the cutting is inserted with sand at its base, *i*. At the end of three weeks the progress of the roots is shown at *j*. GEO. GARNER.

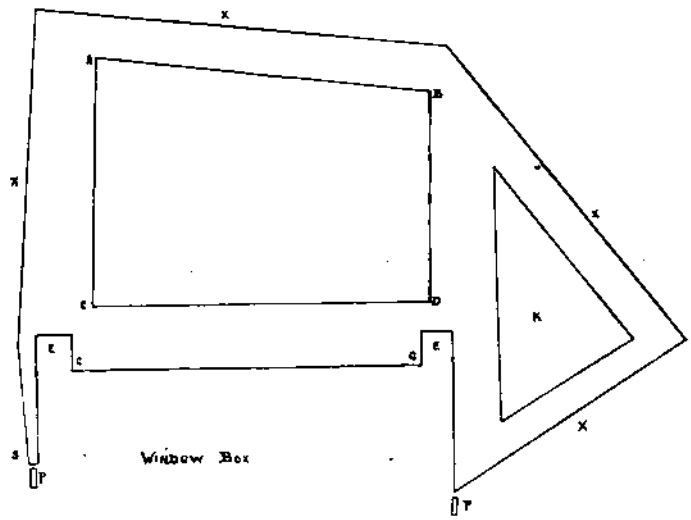
A WINDOW-BOX GREENHOUSE

THE following method of converting an ordinary window-box into a temporary greenhouse during the winter months may prove useful. It has the great advantage of being economical, and of being easily removed, so as to be available for ensuing winters.

Two end pieces are set up, being cut out preferably from three-ply wood in accordance with the pattern shown in the accompanying sketch. The projection in front, though not absolutely necessary, is advisable, as it gives more room for the plants inside, and accommodates any of them, that while growing, have extended over the front of the box. Three-ply wood can be bought by the square foot, but the most economical way of obtaining it is to buy an empty tea chest made of this material from the grocer. These can be purchased for a few pence, and will provide wood for at least two boxes. Hinged doors with a fastening should be provided in each end piece, so that during the warmer days they can be left open. They are also useful for allowing the box to be watered occasionally. Having erected the end pieces, which should, preferably, be screwed to the box, a length of Windowlite is spread over, and attached to them, and to the box, back and front. This is done by screwing battens on to the edges of the end pieces, and the front and back of the box, the Windowlite being secured beneath the battens. In order to ensure the screws holding in the end pieces, strips of three-ply wood should be screwed on to the end pieces along their edges.



a b c d Frame door covered with Windowlite, hinged along side *b d*. *e e* Spaces for the reception of the sides of the box. *g g* Ground level of the box. *k* Window covered with Windowlite. *x x x* Strips to be attached along these edges on their inner side to provide grip for screws holding down Windowlite and retaining battens. *p p* Battens securing Windowlite to box. (Measurements as convenient.)

Windowlite is a new material, which can be bought at most establishments selling building material, such as the Army and Navy Stores. It consists of oiled paper strengthened with fine wires, and is transparent and weatherproof. It varies in price according to width, that for 28ins. wide being 5s. 7d. a yard, but it can be obtained wider. Though it is very pliable, it is not advisable to bend it back on itself. H. C. EVANS.

MY IXIA BED

THE article by Mr. Canning-Wright in THE GARDEN of October 25th was of special interest to me, because I have in my little garden a bed which was made in the summer of 1922 for the less hardy bulbs, and is much on the lines that he suggests. Because it was meant for ixias in particular it has always been called the ixia bed, though ixias are only one race of its inhabitants. It is not a border, but a bed measuring 4ft. 4ins. long by 2ft. 8ins. In even so small a space many bulbs in many varieties find a home, and I could have arranged for a still larger collection if I had begun with the experience I have now gained. For I frankly admit that my aim was not so much to have a bed which should be beautiful as one in which I could grow many kinds: I wanted a collection of plants growing happily rather than a picture. Yet it is something of a picture too; one always has a picture where there is a happy plant.

The ixia bed is raised some 10ins. above, and at the edge of, a larger bed, itself raised above the level of the path, and is backed by a south wall. It is enclosed in slates—better, I thought, than stones, because they would allow more sun-heat to pass for the ripening of the bulbs. The foundation was several inches of small stones for drainage, as Mr. Canning-Wright prescribes. The soil of this garden is not that "fibrous yellow loam" of which he speaks, but is a very cloggy, shaley loam. This was mixed with some loam from the hedges and with plenty of sea sand. If I were making the bed again I should put leaf-mould for most of the loam, and even more sand. A warm, light, well draining medium is what is wanted. The surface of the bed slopes slightly from the wall so as to get still better exposure to the sun.

One luxury my bed is indulged with which would not be feasible for a larger border. It has a light, not so much to keep out frost as to keep off some of that abundant rain which we get here so near the sea in North Cornwall. In the wall behind the bed there is a board with hooks in it, and the light is fitted with rings at the back. It is not meant to come down close to the slate sides, but is held some distance above the bed by a prop which catches it in front. The ixias, etc., are growing in the winter, and the light, if it were not several inches up, would bend their foliage unduly. In the winter—say from now to March—the light is kept handy to the bed, but is off, or lifted by a string which catches up the front of it to the wall behind, both by day and night, whenever rain or a touch of sharp frost does not make it expedient to give protection.

And what bulbs are in this bed? Its size, of course, rules out those large-growing ones which Mr. Canning-Wright mentions, such as Watsonia and Galtonia candicans. But there are many smaller treasures which he also enumerates and so well describes. I put my various bulbs roughly in groups, and have kept a little plan of the bed with their places marked. Of course, there are ixias in mixture, and a special cluster of that Ixia viridiflora which Mr. Canning-Wright singles out for recommendation—a most surprising flower to the majority of visitors Then there are Morphixia paniculata—only a couple of bulbs, but they show their grace and quality—Ixiolirion Pallasii, babiana, sparaxis, Tritoma rosea, Brodiæa laxa and Anomatheca cruenta. There are a few oxalis too; O. Boweii round the edge prospers, and one precious O. lobata has been charming this autumn with its rich yellow flowers delicately curled and pencilled. Some bulbs were also put in which do not need such a privileged condition, as Muscari Szovitzianum, Anemone fulgens, Puschkinia scilloides and Chionodoxa Luciliæ; but they brighten the bed in the earliest spring while the Ixias are getting ready, and they do not resent their pleasant places. Then there is a corner for tigridias, which are left in through the winter and seem to be increasing. They bloom rather late, and this year their beautiful flowers have suffered sadly from the continuous rain. But the tale would not be complete without acknowledging failures. The worst have been Ornithogalum arabicum and Cypella Herberti, with Oxalis versicolor and an unidentified Oxalis species. These did not even come up, and I think that the bulbs of the two first must have rotted in the excessive wet just after they were planted and before the light was made for their protection. Oxalis seems always to be uncertain. All the bulbs that have flowered have ripened seed. Of what I collected I put some into the bed itself to see what happens and some into pots. Ixiolirion, for instance, grew and has been planted out elsewhere. I sow the seed as soon as it is ripe.

Now one or two suggestions of experience for improvement. The bulbs in this bed fall into three divisions of flowering-time. First come such as Muscari and Anemone fulgens; then the ixias and the other small Cape bulbs; then, in the late summer, the tigridias from Mexico. And, of course, each of these has its season to disappear completely and to give space. At this moment tigridias are over and are ripening their seed before they vanish till next spring. The earliest hardy bulbs are coming up and, with, perhaps, Anemone fulgens, will begin to bloom in January. Ixias are well up too, but their group will not bloom till April and May.

Now comes a question which only time can answer. Some time ago I got a bit of Paronychia Kapela. For paronychias Mr. Reginald Farrer suggests a special use. They make, he says, "a carpet for rare little bulbs." So I put P. Kapela into the bed, and there it is becoming a coverlet, spreading over half already. What will be its effect on the other occupants of the bed? Will it keep the sun from ripening their bulbs? Or will it absorb superfluous moisture and help to keep them dry and warm? ST. ERVAN.

BOOK REVIEW

THE name of Messrs. Longmans, Green and Co. has long been associated with the publication of excellent volumes dealing with some phase of gardening, and to those of recent date already published there falls another to be added to that already lengthy list, namely, "My Garden Book," by John Weathers (Messrs. Longmans, Green and Co., 39, Paternoster Row, London, E.C.4; price 36s. net). The author's name is well known to the majority of those engaged in the commercial side of horticulture, as his book on "Commercial Gardening" is still consulted as a standard work, and it thus serves as a useful criterion when we come to judge of this, his latest production. Mr. Weathers has had almost forty years' experience in the various branches of horticulture, and hence can speak with authority from a vast store of knowledge gained over that period. It is often said the more one knows of a subject the less he is inclined to transfer his knowledge to paper, but if everyone followed that axiom, succeeding generations would suffer through falling into the same errors that had been committed by their fathers and forefathers. The thread of personal experience which runs through the volume is one of its most valued assets. There is little that is new in the course of the text. Rather should it be looked upon as a comprehensive treatise on gardening, dealing adequately with its theory and practice. It may, in other words, be looked on as an encyclopedia of gardening confined within the limits of a single volume. A rapid survey of the contents will suffice for the reader to gain something of the immensity and completeness of the book. The book is divided into six parts, making for ease in referring to any particular part. These divisions deal with garden construction and their upkeep, with, in addition, a few chapters devoted to what might be conveniently termed elementary botany and physiology. These chapters are written in fairly simple non-technical and direct language so that he who runs—be he amateur or professional—may read and understand. Several parts of these chapters could have been conveniently omitted, as they come more within the scope of a botanical work than a work on gardening even allowing it to deal with theory. Such paragraphs on the ascent of sap, the facts concerning which even at present the botanist is in grave doubt about, osmosis (a study beset with many pitfalls for the uninitiated in the science of physics), the selective properties exhibited by roots, the descriptions of dicotyledons and monocotyledons, stem structure and the chapter on leaves (altogether too botanical). The average gardener is content to let the study of such subjects remain in the sphere of the botanist, and although they have a direct bearing on the raising of plants and crops, it would perhaps have been better to have left these things unsaid. Such small details, however, are not of much importance when one takes into consideration the size and nature of the volume. Part II deals with the hardy flower garden, in which much useful, descriptive and cultural information is given on the formation and upkeep of herbaceous borders, descriptive lists of herbaceous annuals, biennials and perennials, hardy and bulbous plants and a wealth of detail on hardy shrubs. The conservatory and greenhouse, with a list of desirable plants with which to furnish them, is adequately treated in Part III. Part IV is devoted to fruit, in which is included chapters on insect and fungus pests and remedial measures to be taken to ensure successful results. The vegetable and the herb garden are treated in Part V, while the last part is more or less general, having a calendar of work and an excellent index.

The volume contains a perfect mine of information furnished with a wealth of detail set out for the greater part in a most simple and lucid style. An interesting feature of the book is, as the author points out in his preface, that the derivation of all generic names are given, which lends a decided educational and instructive value to the work. To the gardener, for whom the volume is primarily intended, the descriptive lists of plants, vegetables and fruit suitable for various purposes will be found to be of enormous value. In this way it resembles a miniature encyclopedia. It is a volume which the practising gardener, be he an amateur or professional, will find of the greatest possible service in his daily duties. It brings home to one the scope of gardening taken in its entirety, and such a complete work will be found of great assistance as a work of reference. It is copiously illustrated by means of excellent half-tone blocks, made from photographs of the late R. A. Malby, many of which are well known to readers of THE GARDEN, and numerous line drawings. There are twenty-four coloured illustrations, which might well have been omitted as they detract from the general appearance of the book. The colourings are altogether too rich and warm to be true to Nature, and from them the reader gains neither a true idea nor representation or perspective of the subject dealt with. In these days one must rely on colour photography to reach as close as possible to natural colours and effects. The volume is excellently printed throughout and reflects great credit on the publishers.

G. C. T.

"THE British Journal Photographic Almanac for 1925" (Henry Greenwood and Co., Limited, 24, Wellington Street, Strand, London; price 2s.) is again to the fore. It is the ideal handy manual for all busy photographers who wish to have a book to which to refer.

CATALOGUES RECEIVED.

Messrs. Little and Ballantyne, Carlisle.—Trees, Forest, Fruit, Ornamental and Evergreen, Alpines and Roses. Enclosed in the catalogue is a brief but interesting article by Mr. Stanley Francis dealing with the question of home forestry and the future outlook. It will prove a timely reminder to all owners of woodland who are now taking an increased interest in afforestation, which has now to be regarded as a problem of the greatest national importance.

R. C. Notcutt, Woodbridge, Suffolk.—Nursery Stock, Alpine and Herbaceous Plants for 1925. An excellent catalogue, well illustrated by means of numerous half-tone blocks.

William Artindale and Son, Florists and Nurserymen, Nether Green, Sheffield.—Hardy Herbaceous and Florists' Flowers.

William Watson and Sons, Limited, Killiney Nurseries, Killiney, Co. Dublin.—Ornamental Shrubs and Fruit Trees.

H. J. Jones, Ryecroft Nurseries, Hither Green, Lewisham, S.E.13.—Hardy Plants, Gold Medal Chrysanthemums, Phloxes, Michaelmas Daisies etc.

Ernest Ballard, Old Court, Colwall, near Malvern.—New Asters.

Herd Brothers, The Nurseries, Penrith. Forest Trees and Fruit Trees.

Storrie and Storrie, The Nurseries, Glencarse, Perthshire.—Fruit Trees and Bush Fruits.

J. W. Cole and Son, Westwood Nurseries, Peterborough.—New and Choice Chrysanthemums and Zonal Pelargoniums.

Charles Turner, The Royal Nurseries, Slough.—Roses, 1924-1925.

The Gardeners' Royal Benevolent Institution Seventy-ninth Anniversary Dinner.—£10,000 Raised for Aged Dist... Horticulturists.—The seventy-ninth anniversary dinner held on November 25 will be memorable in the annals of the Gardeners' Royal Benevolent Institution, for on the occasion His Royal Highness the Prince of Wales, presided at the festival and also the wonderful record sum of £10,000 was raised for this deserving institution.

The Prince of Wales in rising to propose the toast was enthusiastically received. He said: "Though I have been privileged to be president of the Institution since 1919 this is the first time I have been able to preside at the festival dinner. I am very glad that, by taking the chair to-night, I am able to associate myself with such a deserving charity, and one which must make a special appeal to Englishmen, to whom the words 'gardening' and 'horticulture' mean so much."

The occasion was one of unusual interest. An anonymous donor had offered £[illegible] on condition that contributions of another £9,000 were announced that night, and an excellent response was made. Card after card went up to the table, increasing, and in many cases doubling, the contributions already promised, until the Secretary was able to announce that the money required to meet the generous offer of the anonymous friend had been secured.

Mr. Leonard G. Sutton, C.B.E., Chairman of Committee of the Gardeners' Royal Benevolent Institution, in replying to the toast said that: "The interest of gardeners must go straight to the hearts of all Englishmen, for they all loved flowers. If they had not a garden in which to grow them, they bought them and put them on their tables." In the course of his remarks, Mr. Sutton alluded to the interest the Royal House had taken for so many years taken in horticulture and the Gardeners' Royal Benevolent Institution, recalling that fifty-three years ago His Highness the Duke of Teck, the grandfather of the Prince of Wales, presided at a similar gathering to the present one, and forty years ago His Royal Highness the Duke of Connaught also took the chair at the festival dinner. Mr. Sutton said how much this interest on the part of the Royal House had enabled them to go forward in the confidence that they would be able to give substantial help to the numerous applicants whose cases were, every week, being brought before the Committee.

GARDEN WHEN YOUNG

IT is a curious fact that there is an almost universal mistake in gardening. Let me explain it as best I can:

There are three stages in gardening—that of the beginner when he is principally interested in anything which gives a quick return; the middle stage, where interest is taken in gardening as a whole and everything that grows is taken into the gardening maw; and the final, which tends more and more towards specialisation, usually in the direction of individual genera of trees and shrubs. Now, the first and third stages should be reversed. Why should a man—or woman—who has passed middle-age suddenly become passionately devoted to trees and shrubs, which take years and often decades to come to maturity? Oaks and large rhododendrons are cases in point. They are in the heyday of their popularity just now. They are keenly sought for, but there is hardly a plant in the garden which is a slower grower. It is a curious phenomenon, why so many keen gardeners past their prime of life should take such an interest in them. This is not meant disrespectfully; rather am I filled with wonder at their disinterestedness and unselfishness in planting trees which they will never see in their full glory. This may partly be due to the fact that old age likes to have something substantial about it on which it can rely, whether it be a human or a plant in the garden. The natural sequence of events would be that all over fifty years of age should specialise, if they specialise at all, in annuals, biennials, herbaceous plants, alpines, small shrubs—anything, in fact, of which they can see the fulfilment.

Rather does the fault lie with youthful gardeners, who are so impatient that they have no thought for the future. All their ambitions lie in the direction of immediate results. They will argue for hours upon the merits or demerits of a plant in the herbaceous border or rock garden. The years pass so quickly that before they know where they are they are middle-aged and the real time for tree planting is past. Is it not better to plant trees and shrubs when young and devote your attention to quick result when older?

This may sound as if the sentimental side of gardening was too much stressed, but there is some common-sense about it. We frequently hear regrets that some plants were not planted years ago, or complaints from people that it is little use mentioning slow-growing plants because they are too old to see them mature. After all, everyone likes to see the result of their handiwork.

This brings me to the fact that gardening is supposed to be the recreation for middle or old age. This is also supposed to be the age of violent exercise, which is probably the reason why so few young people take up gardening as a hobby. Yet there should be time for a little of everything, if that everything is carried out with moderation. Young people should be taught to take an interest in gardening at an early age, and horticulture has so many facets that it should not be difficult to find one side at least with which to attract their interest.

There are numbers of colleges and schools which are devoted to teaching agriculture and horticulture. These are deservedly popular, but by young people I do not mean those who are going in for the cultivation of plants as a profession, rather are my remarks directed at those who from environment or other reasons will ultimately live in a suburban or country area. They will in time possess a garden and will probably become keen gardeners. They should learn something about them now. This knowledge need not necessarily be book knowledge; the main thing is that their curiosity should be aroused; they should keep their eyes open and learn to admire a plant. Once they are interested the rest is easy. Questions will be asked and a modicum of the information received will be stored for future use and so in time they will automatically become keen horticulturists. Horticulture is an insidious hobby and once a man is caught in its toils there is no escape, but I have never heard of anyone complaining.

There is one rule in gardening, however, which should be more recognised: design positions for slowest growing plants first and get them in, even before paths are made. A year wasted is a year lost.

DOUBTS AND DISCOVERIES

BY H. A. GREATOREX.

THE EARLY AUTUMN-FLOWERING CROCUSES.

At the end of the war the trade in the crocus species found itself, as indeed did much else, in a state of demoralised confusion. So great was this confusion that an order for any particular species sent even to the best nurserymen was likely to result, not only in no single specimen of the species ordered, but in a medley of three or four or even more species of a totally different kind. It seemed as though one stood as good a chance of getting what one wanted by ordering a hundred or two mixed species as by ordering by name.

This was the time that I chose to furnish my garden with every kind of crocus species which I could find in the nurserymen's lists, with somewhat surprising results. I felt that something was wrong when I handled the corms. They varied so much in appearance where they should have been alike, and some whose corm-tunics I remembered in other days were palpably wrong. However, I was much too eager to see my crocuses in flower to return them. I planted them in my garden in nice little groups according to their several names, marked their positions, noted them in my notebook and hoped for the best. A month or so later zonatus thrust its spikes through the soil and opened its flowers. Here could be no question. It was zonatus without a doubt. Then in a few days chrysanthus fusco-lineatus, which for some time had been displaying a most strange activity while its neighbour, chrysanthus fusco-tinctus slept, burst into startling bloom, and revealed itself as speciosus! This was but a beginning. Group after group broke into flower. Winter-flowering and spring-flowering crocuses seemed to have lost all sense of season, and where speciosus did not appear there was sure to be Salzmanni erectophyllus or ochroleucus. A few of the groups proved to be correctly named. Of the rest some were wholly wrong, some contained a corm or two of the species named mixed with one or more other species, and some species, wholly absent from their proper groups, appeared here and there as isolated specimens in various parts of the garden. Iridiflorus surpassed all other kinds, for while, among the corms of speciosus and Salzmanni erectophyllus masquerading as this fine species, no single corm of its own kind was found, there did appear one solitary specimen of Karduchorum, a crocus not at that time listed by any nurseryman known to me.

A BEAUTIFUL AUTUMN CROCUS, C. PULCHELLUS ALBUS

Things are better now, and most of the species listed can be relied upon to be true to name, though there are still a few which cannot be trusted.

The sorting out and naming of these crocuses has been a puzzling but fascinating labour. When one possesses all the members of an allied group it is comparatively easy to identify each member. It is not so easy, however, when some of the members are missing, and when only one member is present the problem is difficult indeed.

Anyone who has bought crocuses during the past few years and is puzzled to account for the phenomena displayed should read Mr. Bowles' most excellent handbook of the genus, though even with this aid all difficulties will scarcely vanish immediately.

Zonatus presents no difficulties. It can be obtained true to name from various nurserymen. Its queer, flattened, shapeless corms, rosy pink ground colour, orange throat and white anthers render it practically unmistakable. Its ally Karduchorum looks to the casual observer like a greyish blue toned zonatus without the orange spots in the throat. I do not think it can be bought at present. I have seen it listed for the past four seasons and have bought it each year. The first two years it turned out to be ochroleucus, last year it was Salzmanni erectophyllus, and this year ochroleucus again. Although I have failed to get it under its own name, two corms have reached me, one as mentioned above in a batch of alleged iridiflorus, and one among some zonatus corms. Both corms flowered. One behaved as did those described by Mr. Bowles in his Handbook, sending out its flowering shoot almost horizontally; but because of my very shallow planting this shoot had no difficulty in reaching the light. The other sent up its shoot perpendicularly. Both produced healthy leaves, and both failed to appear next year. I am sorry, for the flowers are attractive.

Pulchellus calls for little comment. It is supplied by the nurserymen true to name, and its identification should present no difficulty. Its orange spotted throat, dark veining and white anthers are rather suggestive of zonatus; but its full-toned, lavender flowers and neat, rounded corms are quite different.

No confusion, either, should arise over the type form of speciosus; but this is a very valuable species, and its many forms are a little perplexing. The form which I receive as Artabir, and which I believe to be correctly named, has neat, medium-sized flowers, paler than in the type, but fairly heavily veined. It flowers at about the same time as the type form; but, possibly because of its more floriferous character, always remains in flower with me for some days longer. The variety which is sent to me as Aitchisonii, and of which I have some doubts, is a very large-flowered, late-flowering, pale form. It comes into bloom a day or so after the last flowers of the type form have rotted away. The buds and the outside of the closed flowers have a silvery grey appearance, due to a freckling of greyish blue purple on an almost white ground, and the inside of the segments is heavily veined, as much so I think as in the type, though both the ground colour and the veinings are much paler in this variety, being of about the same tone as in Artabir. In the mass, however, at a little distance, I find a hint of the blueness of blue sky which I cannot see in Artabir, and the outsides of the buds of the latter form have much more colour. The cross veinings of the flowers for their first two days are strikingly beautiful. This does not quite agree with Mr. Bowles' description of Aitchisonii as a flower less veined than the type and of a pale uniform shade of lavender within; but if it is not Aitchisonii, what else can it be?

Digitized by Google

C. SPECIOSUS, THE TYPE FORM OF A VALUABLE SPECIES.

The variety albus as supplied by Messrs. Barr contains more than one form, some individuals having a duskiness at the throat which is absent from others. Among these white forms I always find a few coloured specimens of a rather peculiar type. They are all pale forms and are practically free from the grey-blue frecklings on the outside of the segments generally so characteristic of the species. All of them have the inside of the segments of a pale lavender blue, only faintly veined. In some the outside of the segments is of a pale lavender blue, in others almost white, and one I have, with enormous flowers, which has the outside of the segments of the colour of white satin and the inside lavender with the cross veinings almost absent.

Many other forms, some of them very distinct either in colouring or in their season of flowering, are sure to turn up as occasional strays in any considerable batch of crocus species bought to-day. Such at least is my experience.

A WHITE WISTARIA

THERE ARE NO MORE CHARMING AND GRACEFUL SPRING-FLOWERING SHRUBS THAN THE WISTARIAS.

ALTHOUGH popularly known as the Japanese wistaria, this noble climber is considered to be native only of North China, and was introduced from Japan to Belgium by Siebold, and in 1874 the first plants found their way to Kew Gardens. Undoubtedly the noblest of all woody climbers so far introduced to this country is this and its allied species and their beautiful varieties, which, during their period of bloom, become features of outstanding loveliness. Equally adaptable are these magnificent climbers for clothing the walls of houses, pergolas, arbours and similar positions, or even large trees, through the branches of which their long entwining growths spread with amazing luxuriance; and as a bush in the open there is not, even among the vast number of hardy flowering shrubs, anything to equal the graceful charm and distinct beauty of these glorious wistarias. A good and fairly heavy moist loamy soil is what all the wistarias delight in, and this they thoroughly deserve, whether planted in the open, at the foot of walls, or near a large tree.

In the latter case it is advisable to take out a large hole 3ft. square and make good with turfy loam, thus enabling the wistaria to become thoroughly established, with the growths reaching the branches of its host tree before the latter's roots have seriously penetrated the new soil.

Other methods are adopted for supporting this handsome climber, in the form of skeleton iron framework, and this practice contains much that is good as it allows the slender racemes to fall to their full extent and permits of their being seen and enjoyed from every point of view, the beauty of the flowers being enhanced by the gentle shading of the interior.

The illustration is that of W. multijuga var. alba which annually provides a feast of bloom. Thousands of its pure white pendulous racemes—often reaching 3ft. in length—grace the sides of pergolas and various buildings, giving their interiors a delightful lacy aspect.

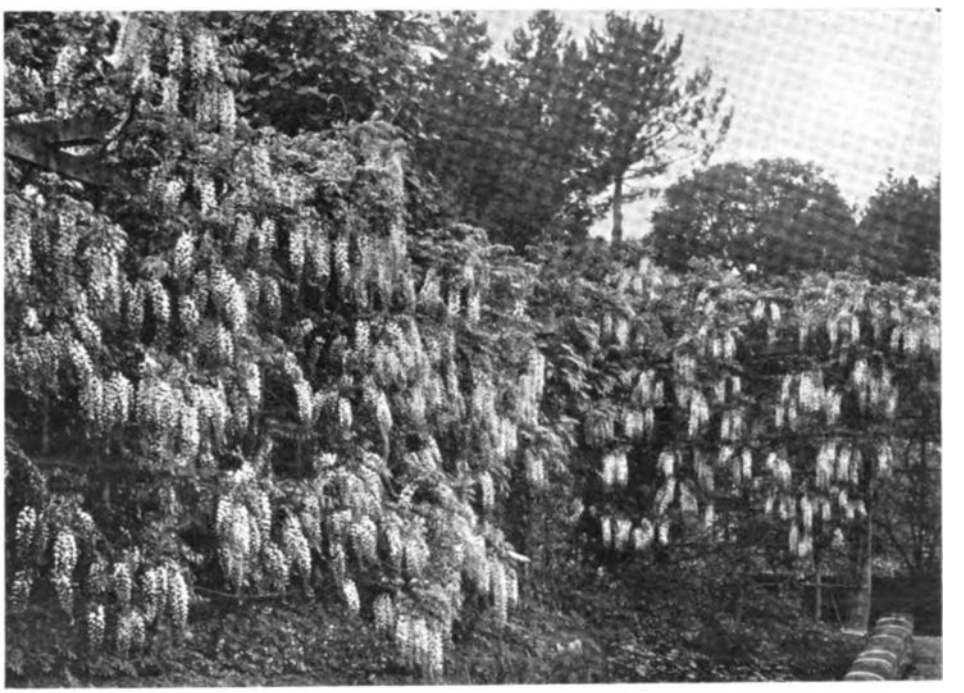
Pergolas intended for this variety and, indeed, all the multijuga group should be built taller than is the usual custom, owing to the great length of their inflorescences. Much of the beauty and gracefulness is often lost to these choice climbers by injudicious pruning, it being the practice to cut the side branches hard back from the start; this, however, is wrong, and robs this glorious climber of much natural grace and charm.

The growth should be encouraged to stand out—at least, wherever such is possible—from 3ft. to 4ft. from its supports, in which condition the branches become stout and self-supporting, and by reason of their profusion of bloom the effect is superb.

A very important point which concerns this white variety of W. multijuga is that it flowers a fortnight later than the type and its charming rose variety, and this characteristic renders it an even more precious shrub for gardens, as by the time its flowers have reached their best most of the violent storms are past.

Three distinct kinds of this wistaria are grown here, namely, Wistaria multijuga, with lilac and blue flowers, racemes 3ft. to 4ft. in length; W. m. var. rosea, with lovely pale rose flowers; and W. m. var. alba, with immense racemes of pure white flowers.

It is interesting to note that, whereas this handsome white variety is a fortnight later than the species in coming into bloom here, Wistaria multijuga is about the same time behind the better known and equally desirable W. chinensis. E. MARKHAM, *Gravetye Manor*.



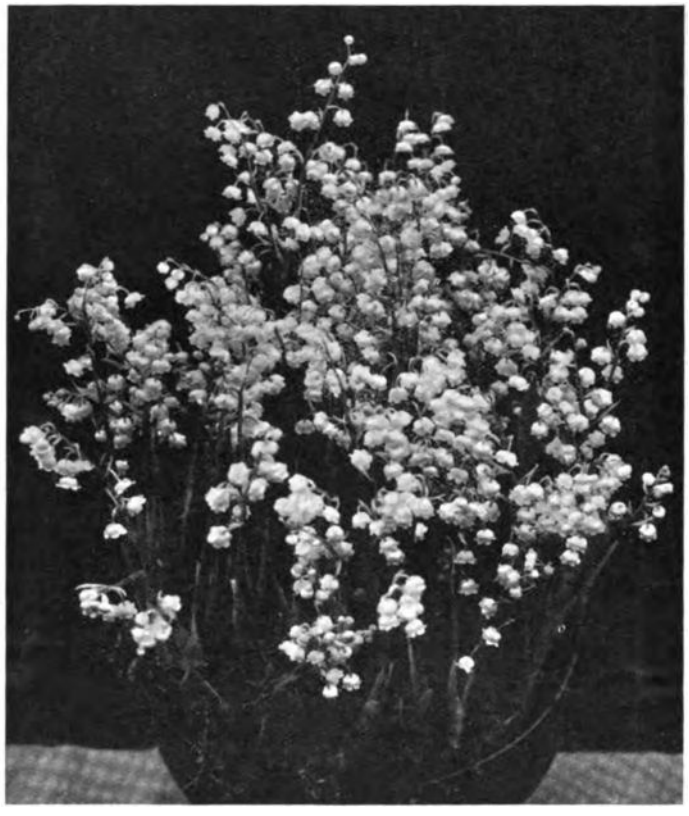
ONE OF THE MOST BEAUTIFUL OF ALL WOODY CLIMBERS, WISTARIA MULTIJUGA ALBA ON A PERGOLA AT GRAVETYE MANOR.

Digitized by Google

LILIES OF THE VALLEY ALL THE YEAR ROUND

THESE DAINTY HERBS HAVE LONG BEEN PRIZED FOR THEIR DELICATELY SWEET SCENTED FLOWERS; AND, AS THEY ARE HARDY AND EASILY GROWN IN PARTIALLY SHADED PLACES, THEY SHOULD FIND MUCH FAVOUR FROM FLOWER LOVERS.

AMONG spring flowers there is scarcely one to compare in beauty, fragrance, purity of line and grace of form with the lily of the valley. In the cut-flower market it can be obtained practically all the year round, and considerable trade is done, though at certain times of the year the price is of necessity high. There is no reason why lovers of these charming flowers should not, by taking a little thought, obtain lilies of the valley throughout the whole year from their own garden or greenhouse. Let us assume that lilies of the valley are grown in a border outside and that the question of forcing them has not already been considered. Even at this late hour flowers can be obtained in a comparatively short time if imported crowns are purchased and forced at once. By bringing these crowns at intervals into a fairly high temperature a succession can be maintained until the crowns in the borders are in bloom. The Berlin strain of imported lilies of the valley is most successful for forcing; Fortin's and Victoria varieties are excellent for general purposes. As soon as the bundles arrive from the nurseryman they should be untied and potted up. A sufficient number of 5in. pots should be well drained, ten crowns placed in each in an upright position and a leafy compost lightly packed in, leaving ½in. of the crown exposed. This fairly loose potting allows heat to pass through the soil, so that the roots are kept in a warm state. If preferred, boxes can be used instead of pots, and in that case the crowns should be placed at a distance of 1½ins. apart. When the work is finished the pots should be well watered and stood outside. No covering is required, as lilies of the valley benefit from exposure to frost before forcing is started.



THE SMALL WHITE DROOPING BELLS OF LILY OF THE VALLEY.

The first batch should be taken into the house for forcing after a few days and the remainder left in the same position in the open. The latter should be brought inside at regular intervals. Forcing takes from four to six weeks, the late batches forcing more readily than the early. The most important consideration in forcing is the temperature, which should be about 70° Fahr., while a bottom heat of at least 80° Fahr. is essential. Until growth has started the pots should be kept in darkness by inverting over each another pot; or if boxes have been used, light can be excluded by placing boards over the top. Unless this is done the flower spikes come up alone and no leaves appear. Feeding is not necessary, but an occasional syringing with warm water is very helpful. Warm water alone should be used for watering. Only the late forced batches are worth saving for future use. After the flowers of these are cut the crowns should be planted outside, and in a year's time they will have gained enough strength to enable them to flower in the border.

Home-grown crowns can be used for forcing instead of the imported ones, when the necessary steps are taken. If the beds from which the crowns are lifted have been well prepared and given liberal treatment, home-grown crowns are as good as, if not superior to, imported ones. When the time comes in September for the lilies of the valley in the border to be transplanted—as a portion should be each year—the required number of crowns for forcing should be potted up and stood outside. Only three year old crowns are suitable for this purpose. The first batch should be brought inside for forcing by the end of November.

The size and quality of the flowers in the borders depend on the situation and particularly on the preparation of soil. When transplanting, a position in partial shade should be selected—under a north or west wall is ideal—and the ground thoroughly well dug. Plenty of leaf-mould and some decayed manure should be added. Unless the soil is of an open texture a dressing of sand must be given, for good drainage is most necessary. As lilies of the valley are lifted the weeds should be removed from among the roots and the crowns should be sorted and planted in different beds according to their size. They will be found to be in three sizes, the new crowns formed the current year, those formed the year before, and those which are at least three years old. A shallow drill should be taken out of the prepared ground and the crowns placed 3ins. apart in an upright position. The drill should then be filled in so that the points of the crowns are just below the surface. The next drill should be started at a distance of 9ins. from the first. When the beds are completed they should be covered until the following spring with a layer of leaf-soil.

Before the last flower in the shady border has been gathered, in order to avoid a break in the supply, "retarded" crowns should be purchased every few weeks until the forced crowns in the houses are once again showing their flower spikes in January. These crowns known as "retarded" lilies of the valley arrive in this country tied in bundles and are put immediately into cold storage. There they remain in a dormant state for two or three months—at a temperature of 28° Fahr. As soon as the crowns are received from the nurseryman they should be very lightly potted in a leafy compost, because growth begins at once without any forcing or feeding whatever. In about three weeks after potting the flowers are ready for cutting. A temperature of 65° Fahr. is all that is necessary for "retarded" crowns. The pots should be given the same treatment

Digitized by Google

as advised for forced crowns, but they should be shaded, even after the covering is removed, if the sun is at all strong.

It is at least possible that, because there are many calls on the garden-lover's time in the hey-day of his year, there will be some weeks when there are too many urgent things on hand to allow time for potting lilies of the valley; but there is consolation in the thought that, directly the pressure of work is lessened, some more "retarded" crowns can be purchased and the succession assured. Who can deny a warm welcome to the fragrance and slender beauty of the lily of the valley? Who will refuse to acknowledge its grace, which can be enjoyed the whole year round?

THE SOUTHERN BEECHES

BY W. J. BEAN.

IN A PRECEDING ARTICLE THE AUTHOR DEALT WITH SPECIES OF NOTHOFAGUS FROM SOUTH AMERICA. IN THIS ONE HE CONFINES HIS ATTENTION TO THOSE SPECIES FROM AUSTRALIA, NEW ZEALAND AND TASMANIA.

AUSTRALASIAN SPECIES.

N. CLIFFORTIOIDES.—In New Zealand, where this tree is commonly called "mountain birch," it grows to about 50ft. high, with a trunk 1½ft. to 2ft. in diameter. There are trees more than half that height in the south-western counties, but it is rather a rare tree. For many years a specimen, ultimately about 12ft. high, grew in Messrs. Veitch's nursery at Coombe Wood. I remember it being there about thirty years ago, so that, although it grew so slowly, it must be considered as capable of bearing considerable cold. But Coombe Wood, being elevated and with a slope to the south, is rather favourably placed; on the flat, low-lying site of Kew it is not hardy. It is evergreen, and its leaves, mostly oval or ovate, are about the smallest among the southern beeches, being only ⅛in. to ¼in. long and ⅛in. or less wide. They are set in two opposite rows along the dark, wiry, downy twigs, ⅛in. to ¼in. apart, are without teeth on the margin, and, on young trees, are free from down on both surfaces; the very short stalk, however, is downy like the twigs. On some branchlets from adult trees in New Zealand that I have preserved, the lower surface is covered with a close felt. This is a charming and very distinct small tree where it thrives well.

N. CUNNINGHAMII.—In Tasmania this becomes a very fine tree, its dimensions as found there at low elevations being given as occasionally 200ft. in height with a trunk 40ft. in circumference. It is not hardy in our average climate, but in the south-western and other of the milder counties is thriving excellently. There is a well known example at Osborne in the Isle of Wight which must now be approaching 40ft. in height, but still finer ones are at Kilmacurragh and Fota in Ireland. It is evergreen and has the thin wiry twigs so characteristic of these trees. The leaves are usually ⅛in. to ¼in. long, diamond-shaped to triangular, and conspicuously toothed. The husk, which encloses three nuts, is curious by reason of numerous gland-tipped processes growing over it. I have seen good crops of fruit on the Osborne tree, but all, I believe, infertile.

N. FUSCA.—This is one of the fine evergreen trees in which New Zealand is so rich, becoming there 100ft. in height with a trunk 7ft. to 8ft. in diameter. The branchlets are curiously zig-zagged and when young are covered with minute down. The leaves are roundish ovate, but quite distinct from those of any other species in having three to seven comparatively large incurved teeth on each side; they are ¼in. to 1½ins. long, dark lustrous green above, pale green beneath, smooth on both surfaces. While it is one of the most distinct and curious of the nothofaguses, it is not, to my taste, one of the handsomest. In a young state at least it is somewhat thin in habit and not luxuriant in foliage, but the old leaves turn purplish in winter and a brilliant red before falling in spring, just as the young ones are unfolding. It is not apparently one of the hardiest, although it lived outside at Coombe Wood for many years, but grew slowly.

Photo R.B.G., Edin.

NOTHOFAGUS FUSCA, ONE OF THE FINE EVERGREENS OF NEW ZEALAND.

N. MENZIESII.—In a wild state in New Zealand this tree appears to bear a considerable resemblance to a birch, the bark being silvery white, and one of its common names there is "silver birch." It is, however, an evergreen and grows 100ft. high with a trunk 5ft. to 8ft. in diameter. The leaves vary from triangular to diamond shaped, are ⅛in. to ¼in. long, dark glossy green, the margins doubly toothed. In general appearance this tree much resembles N. Cunninghamii; it can, nevertheless, be distinguished by the double-toothing of the leaves (simple-toothed in Cunninghamii), also by two curious tiny pits that often occur near the base of the leaf, one on each side the midrib, each fringed with brown down. These pits are sometimes absent, sometimes there is only one. This nothofagus is rare, but recently I saw it succeeding very well in Mr. Fletcher's fine arboretum at Aldwick Manor, on the outskirts of Bognor where also several other species are in excellent condition.

N. MOOREI.—A native of New South Wales, where it reaches 150ft. in height, this tree is only likely to be hardy in the mildest parts of our islands. A specimen that was over 20ft. high was, some years ago, growing in the open air at Kilmacurragh in County Wicklow. It is evergreen, the ovate or lance-shaped leaves being 1½ins. to 3ins. long, half as much wide, tapered towards both ends but more slenderly towards the apex, finely toothed, dark green and glossy. Excepting N. procera, it has the largest leaves of the southern beeches, but they are not so strongly ribbed as in that species.

N. SOLANDRI.—A New Zealand evergreen tree reaching in that country 40ft. to 80ft. in height, with a slender black-barked trunk 1ft. to 1½ft. in diameter. It is one of the small-foliaged species, the leaves being only ⅛in. to ¼in. long and about half as much wide, oblong, smooth and glossy green above and smooth or nearly so beneath on young trees, but clothed with greyish white down on adult ones. The margins are without teeth. This species is rare in cultivation and appears to be most closely allied to cliffortioides; it occurs wild at the same altitudes and ought to be of about the same hardiness. It may be distinguished from that species by the leaves being rather larger and tapered or wedge-shaped at the base (rounded or somewhat heart-shaped in cliffortioides).

The following species so far as I know are not in cultivation: apiculata and Blairii, New Zealand; Gunnii, Tasmania; Montagnei, nitida and pumilio, South America.

A BECKENHAM ROCK GARDEN

BY W. IRVING.

AS AN EXAMPLE OF WHAT A KEEN LOVE OF ALPINE PLANTS CAN ACCOMPLISH THIS GARDEN DESERVES ALL CREDIT. THE OWNER HAS CONCENTRATED HIS ATTENTION ON SAXIFRAGES. EXCLUDING THE MOSSY SECTION OVER THREE HUNDRED AND FIFTY SPECIES AND VARIETIES FIND A HOME HERE.

AS an example of what can be accomplished in a short time, the beautiful rock garden and grounds of "Edenhall," in Albemarle Road, Beckenham, are testimony to the energy and taste of the owner, Mr. C. Kirch. In the planning of a rock garden of any pretensions the chief factor essential is that of position, with elevation and irregularity. But here is shown how a level surface can be transformed into an ideal one that harmonises with its surroundings.

The ground originally at disposal some three years ago was comparatively level, occupying approximately about 1,000 sq. ft., but, by excavating and building up, the necessary elevations were attained, as well as irregular paths winding in and out between banks and mounds. Water, which is one of the greatest attractions in a rock garden, has been artificially introduced in such a manner as to give it a natural appearance, and at one corner a cascade has been formed. The water falls down the cascade and is led through a series of shallow pools and streamlets at different levels, eventually reaching a central pool planted with nymphæas and other suitable aquatic plants.

At the time of our visit the rock garden was ablaze with colour in a setting of Purbeck stone, of which some 800 tons was used in its construction. This stone is well adapted for rock gardening, and being of a porous nature is eminently suitable for plant life. In the scheme of planting, large masses of each kind has been aimed at, and it is only possible to notice here a few of the principal features of interest. One of the first plants noted was a mass of the garland flower (Daphne Cneorum), with its pink sweet-scented flowers in excellent condition. There were also several species of the ladies' slipper orchid (cypripedium), from North America, including C. spectabile, with its white and rose tinted flowers; C. pubescens, with yellow flowers, and C. montanum, with white ones. These were all represented in colonies in a shady position.

In the shady crevices might be seen the rosette mullein (Ramondia pyrenaica), from the Pyrenees, with its mauve-coloured flowers, along with its more Eastern relatives, R. serbica, and R. Nathaliæ from the Balkans and Haberlea rhodopensis. As companions to these were many kinds of the smaller ferns, like Asplenium Trichomanes, Ceterach officinarum, Cystopteris fragilis, Polypodium cambricum and Adiantum Capillus-veneris to mention only a few which were well established.

Among the crevices of the rock, as well as on the level ledges, both in full sun and half shade, many species of saxifrages were represented by groups of various sizes, such kinds as S. Elizabethæ, S. sancta, S. Paulinæ and S. oppositifolia being prominent. S. Cotyledon, with its long arching sprays of white flowers was in excellent condition as was also S. longifolia, while the mossy kinds were much in evidence. Other popular families, such as the gentians are largely grown, those noted being G. verna, of dwarf habit and rich blue flowers; G. acaulis, the gentianella, with its large trumpets of deeper blue; G. Farreri, to flower later with G. sino-ornata, appears to be thriving happily in various positions. Wide cushions of the mossy phloxes with pink and white flowers, various kinds of dianthus, aubrietias, gypsophilas and numerous other families, all play their part in making an attractive display during the season.

ONE CORNER OF THE GARDEN, WITH A CASCADE.

No rock garden of any pretensions would be complete without some of the slow-growing and dwarf conifers and shrubs, and these have been used with judgment and taste. Among the conifers were Abies nigra, A. pumila, A. Maxwellii, and A. pygmæa, Juniperus tamariscifolia, J. prostrata, with their spreading prostrate branches, the upright Cupressus Fletcheri, and the dwarf C. obtusa var. nana. The flowering shrubs included Cytisus Beanii, C. kewensis, and C. humifusa, of the dwarfer section, while taller-growing ones were C. Andreanus, Prunus pumila, P. triloba, Rhododendron ferrugineum and R. hirsutum.

Many bulbous plants gave evidence of being successfully employed as the various families are represented in colonies freely disposed, like Narcissus minimus, with its tiny yellow trumpets, N. triandrus, with its drooping white ones, the hoop petticoat daffodil (N. Bulbocodium), the blue Anemone apennina from Italy, and the darker A. blanda from Greece. In addition were groups of the grape hyacinths (muscari), scillas and many others too numerous to mention. In a shady recess some North American liliums, like L. Grayi, L. canadense and L. superbum were associated with groups of the trinity flower (Trillium grandiflorum), meconopsis, Epigæa repens and low-growing gaultherias.

In the lower, moister positions, and on the banks of the streamlet, primulas of many kinds are freely employed, associated with other suitable moisture-loving plants like irises, mimulus and such like plants.

An interesting feature was a wall planted with many species of houseleeks (sempervivum), which by reason of diversity of colouring and growth is an interesting feature at all times of the year. They are planted in large masses, and included many of the more distinct kinds, like the cobweb houseleek (S. arachnoideum), the dark coloured S. triste, the well known S. calcareum, and the yellow flowered S. Allionii, among a host of others.

Digitized by Google

As a screen to divide the rock garden from the lawn with its paved walks, borders and rose beds, a dry wall has been built with stone arches giving access either way. Here again the wall is utilised to the fullest extent with suitable plants, and in the crevices such as the rock rose (Helianthemum), Onosma echioides, Lithospermum prostratum, dianthus and others have been used with full effect.

In addition to a collection of the choicer rock and alpine plants, Mr. Kirch has concentrated his attention on the saxifrage family. He aims at getting together all the different kinds in cultivation, and so loses no opportunity in getting in touch with other growers of this popular plant, and by means of exchange or purchase to enlarge his collection. This already consists of some 350 species and varieties excluding the mossy ones.

In the alpine house adjacent to the rock garden numerous specimen pans of saxifraga species and varieties may be seen, mostly in perfect health, though some are not the easiest of plants to grow in this country. Among the many kinds noted were: S. Burseriana, in various forms; the silvery leaved S. lingulata, with its long sprays of white flowers; numerous varieties of S. Aizoon; the yellow-flowered S. apiculata; large rosettes of S. longifolia the queen of saxifrages, the Macedonian S. Grisebachii, with its crozier-like inflorescences of red flowers, besides a large number of hybrids and varieties, many of them still rare in cultivation.

Such a collection gives one an idea of the infinite variety of saxifrages now grown in gardens, and it also brings home the confusion that exists with regard to the nomenclature of the various members of this genus. As the different species hybridise freely it is almost impossible to raise from seed true to type unless great care is taken to isolate the plants before the flowers open. Plants under the same name from various sources differ to a great extent, and are probably the result of seedlings, hence the great difficulty of attempting to keep a collection correctly named. Besides saxifrages, other plants like androsaces of various kinds, the rarer campanulas, dianthi and other alpine plants from higher altitudes are given the shelter of the alpine house where they get the protection they need in our changeable climate.

An inspection of the frames close by reveal that Mr. Kirch is actively engaged in hybridising some of the more important species, and there is a prospect that some interesting kinds may be produced at some future date. Lovers of these plants are assured of a hearty welcome at any time and would doubtless profit from a visit to this most interesting garden.

It may be added that the rock garden was built by Mr. E. Scapelhorn of Beckenham, who evidently gave much thought and consideration in carrying out the design.

Well worth a visit is the rose garden close by, containing all the newest and best varieties, 1,700 in all, in groups of five, which, with a large bed of 100 Golden Emblem, was a blaze of colour at the time of our visit.

HELIANTHEMUMS, LITHOSPERMUMS, DIANTHUS AND OTHER PLANTS ARE UTILISED TO FULL ADVANTAGE ON A DRY WALL.

A GENERAL VIEW OF A SECTION OF THE GARDEN.

ONE OF THE STONE ARCHES, IN THE CREVICES OF WHICH ARE SHADE LOVING PLANT

WINTER FERTILISERS

THERE is a large number of fertilisers which can only be used to the best advantage during the winter months, and I propose in the present notes to consider some of the most important. It is hardly necessary to mention that bones take the premier place in these winter fertilisers, but as they have been considered fully in another article, their use need not again be described in the present one.

About a dozen materials have to be taken into consideration as useful winter fertilisers. These in each case are somewhat slow in action. They comprise a wide range of different articles, some supplying nitrogen, others phosphate, and others still, potash. Their solubility varies enormously, some going completely into solution, while others only dissolve with great difficulty. Water solubility is not an entire guide, as it must be borne in mind that many materials which water takes up very badly are soluble to a remarkably high extent in citric acid, ammonium citrate, and in soil water charged as it is with carbonic acid gas.

The most convenient way of arranging these winter fertilisers for treatment is, I think, in alphabetical order, and I will, therefore, commence with a few notes on

Basic Slag.—It is unnecessary to go into the origin and manufacture of this valuable winter fertiliser, but care should be taken to obtain a sample for use in as finely ground a condition as possible. The contents of soluble phosphate should be high, although such samples will cost considerably more than those in which insoluble phosphate predominates. A high citric solubility, however, will be quite as good as one could wish for. The use of basic slag for lawns is well known, but, unfortunately, it is apt to encourage the growth of clover. For use as a slow-acting phosphatic fertiliser on flower borders it is exceedingly useful, the rate being about a couple of ounces per square yard. For digging into fruit borders and into the vegetable garden, a quarter of a pound can be used for the same area.

Chalk and Limestone Dust.—A word or two only is necessary with regard to these materials, as they can only be regarded as indirect winter fertilisers. They prove very valuable soil sweeteners if worked into the land during November, and heavy dressings can be given with perfect safety, say 30lb. to 40lb. per square rod.

Cyanamide.—This should be used in the late winter, so that the nitrogen it contains can be available for the stimulation of leaf growth in the spring when the plants are ready to take it up. If cyanamide is used extensively there is very little need to lime the land, as carbonate of lime remains in the soil after the ammonia has been released from the material. The rate of application of this fertiliser is distinctly variable. Personally I am in favour of small doses, say 1 oz. to 2 oz. per square yard, but much larger amounts have been given to poor land with good results.

Flue Dust.—This is a very valuable potash fertiliser, the amount of potash it contains sometimes being as much as 10 per cent. It can be readily obtained in industrial districts from manufacturing firms, and if used early in the winter it can be applied in a fresh state at the rate of about a quarter of a pound per square yard. For late winter use it should be well aired before application, and spread on the surface for a week or two before being worked in, to allow certain deleterious compounds to be oxidised, or to evaporate into the air. Used fresh it has distinct pest-killing properties, which make it doubly valuable. I recommend its extensive use on land intended for the cultivation of potatoes and root crops generally.

Gypsum.—Much more use should be made than is made at the present time of this material, especially on land intended for turnips and globe beet, for which it often proves very valuable. The action of gypsum is not at the present time fully understood, but it is thought that it reacts with the locked-up potash the soil contains and releases this for absorption by plants. An application of gypsum is, therefore, equivalent to using a potash fertiliser, and, of course, it is very much cheaper. About 10lb. can be used per square rod.

Horn and Ivory Dust.—These two materials are similar in action and composition, supplying nitrogen to the soil in a slowly available form. They can be readily obtained in cutlery districts and have proved exceedingly valuable as mild stimulants. Both are light, bulky materials, and are almost entirely insoluble in ordinary water. One good dressing—say 10lb. per square rod—will last over a number of years, and, therefore, these materials, which are, of course, generally regarded as waste, prove highly economical. I recommend their use on ground intended for cabbages, potatoes, artichokes and similar crops. Good results have been obtained by giving moderate dressings once in four years to plantations of bush fruits.

Kainit.—This is a well known potash manure of somewhat complicated composition. Its use as a summer fertiliser is undesirable on account of its content of magnesia, salt, etc., and also that it is somewhat slow in dissolving. Used in November or December, however, it proves of great value, and can be worked into flower, fruit and vegetable ground during the winter digging. Light dressings only are given, as a rule, on account of the cost of the material, and up to now it does not seem advisable to use more than about 4lb. per square rod. The value of kainit for lawns is well known, but it often pays also to mix a little in with vegetable refuse to increase its value when this material is being made into a stack, or thrown into a pit to rot down into organic manure.

Muriate of Potash.—This fertiliser is the same as chloride of potash, muriatic acid also being known as hydrochloric acid. Used as a summer stimulant, this fertiliser proves in many cases to be an active plant poison, and loud have been the complaints concerning its untimely application. Used in the winter months, however, its poisonous effect appears to be changed in contact with soil water, and bearing in mind that it is a cheap source of potash, much more use should be made of it than has been done in the past. Light dressings only are recommended, about a couple of pounds per square rod being ample, and ground only should be treated with it where a large content of potash is desired, as is the case, of course, when such ground is to be planted with potatoes or sown with different kinds of tap-rooted vegetables.

Pearl Ash.—Candidly, I do not recommend the application of pearl ash, either as a winter or as a summer fertiliser. It has been highly praised by many so-called experts, but it is too strongly alkaline a material for use with safety on any but very acid soils. Pearl ash is cheap and readily obtainable, of course, but if its use is going to be destructive both to plant tissue and of actual humus in the soil, as it has in several instances proved to be, it is naturally dear at any price. Light dressings only are generally applied, about 1 oz. to 2 oz. per square yard. If used at all it should be worked in as early in the winter as possible.

Reverted Superphosphate.—Just a word about this material, which is often regarded as useless junk. If ordinary superphosphate is not stored in a perfectly dry place complicated chemical changes frequently set in, and the material loses its power of dissolving in water. Technically it reverts to another kind of phosphate, and its solubility can only be restored by the use of strong sulphuric acid. Reverted phosphate, however, proves a most valuable slow-acting fertiliser for use during November, and its application is to be far more highly commended than is that of superphosphate itself, on account of its not rendering the soil acid after application, as the latter does. It is valuable alike for the flower and the vegetable garden, while it has also been used in the preparation of fruit borders with conspicuous success. Relatively heavy dressings are applied in the first instance, as the effect of an application is felt over a period of several years. I recommend about a quarter of a pound being used per square yard at the present time, and it should be promptly dug in.

Spent Carbide.—This consists largely of slaked lime with some carbonate of lime or chalk, and a small amount of unacted-upon calcium carbide. It is valuable as a soil sweetener, and also proves to be a mild deterrent to soil pests, on account of the acetylene gas given off by the unacted-upon carbide. Immediate application is recommended, and in any case it should not be used after the end of December. The rate can be varied from 4 oz. to 8 oz. per square yard.

Wood Ashes.—The last material of the dozen selected is, of course, wood ashes, and I should like to urge that less waste of these is advisable. Gardeners from now onwards will be busy burning up woody garden rubbish, but in at least 50 per cent. of these cases no efforts will be made to keep the ash dry, or to store it until required for use. Wood ashes contain considerable amounts of potash and prove a very valuable late winter fertiliser, especially for land intended for potatoes and other tap, tuberous or globular rooted vegetables. It is not necessary to use sulphate of potash as a summer or spring dressing if one has plenty of wood ashes, and special potato fertilisers (which, of course, consist very largely of potash) can be abandoned and large sums saved by the non-purchase of them. After a bonfire the ashes should be sifted as soon as they are cool, to remove rubbish which has not been fully calcined, and should then be stored in sacks or barrels in a perfectly dry place. The rate of application of this material is about a quarter of a pound to the square yard.

E. T. ELLIS.

CORRESPONDENCE

IMPORTATION OF NURSERY STOCK INTO CANADA.

SIR,—Owing to the fact that an English nurseryman has written to me to say that he cannot fulfil my order owing to restrictions, imposed by the Canadian Government, I should like to draw to your attention that possibly a misconception as to the actual facts *re* importation of nursery stock into Canada may exist among British nurserymen. Since the impression that plants of all kinds from abroad are absolutely barred entry into Canada is likely to prove detrimental to the interests both of British growers and of Canadian horticulture, it seems desirable that the true facts be given proper publicity.

The copies of the regulations governing the importation of nursery stock into Canada (1) from the United States, and (2) from Great Britain and other foreign countries, explain that plants (with certain exceptions), may be brought into Canada, provided that certain formalities are complied with. The essence of the regulations is that the Canadian importer must apply to the Department of Agriculture at Ottawa for a permit to import. This permit is freely given, except in the case of certain trees, shrubs, etc., upon which there is an embargo, and is accompanied by official labels that have to be forwarded with the order and must be affixed by the shipper to the packages containing the plants. The stock is examined by the Department's inspector at the port of entry in Canada, and goes forward to the consignee without further formality other than the payment of Custom's duty. The regulations perhaps make the procedure seem rather involved, but it is, in reality, very simple and I have experienced no difficulty in bringing in plants.

With the United States matters are very different, and American importers have much difficulty in securing permits to import; possibly the fact may have led British growers to believe that the regulations in both Canada and the United States are the same.—HUGH S. SPENCE, *Ottawa*.

[As our correspondent remarks, there are printed copies of the main regulations governing the importation of nursery stock into Canada; these are obtainable from the Department of Agriculture at Ottawa. At the present moment the following restrictions are enforced:

The importation into Canada of merchandise packed in hay, straw or other fodder is prohibited unless—

(1) Such merchandise is accompanied by a certificate from a properly qualified veterinary officer of the country of origin, and that such hay, straw or other fodder has been grown and stored and the merchandise packed in a district not infected by foot and mouth disease.

(2) Such merchandise is accompanied by a certificate from a properly qualified officer of the country of origin to the effect that the hay, etc., used in packing the merchandise has been thoroughly disinfected.

(3) In the absence of such certificates the merchandise shall be unpacked and the packing destroyed under the supervision of an officer of the Federal Department of Agriculture and the cost borne by the shipper.

Importers are advised to notify their shippers accordingly.

Regulation No. 6.—Prohibiting the importation of the following species of Pinus and their horticultural varieties:

Pinus Strobus, *L.*; Pinus monticola, *Dougl.*: Pinus Lambertiana, *Dougl.*; Pinus Cembra, *L.*, and all other five-leaved species of pinus. This is to prevent the introduction of pines susceptible to the white pine blister rust, and those which may be affected by the disease.

Regulation No. 8.—Prohibiting the importation of all species and varieties of currant and gooseberry, not including the fruits. Currants and gooseberries are the host plants of white pine blister rust and it is to prevent the further introduction of this disease that importation of these plants is prohibited.

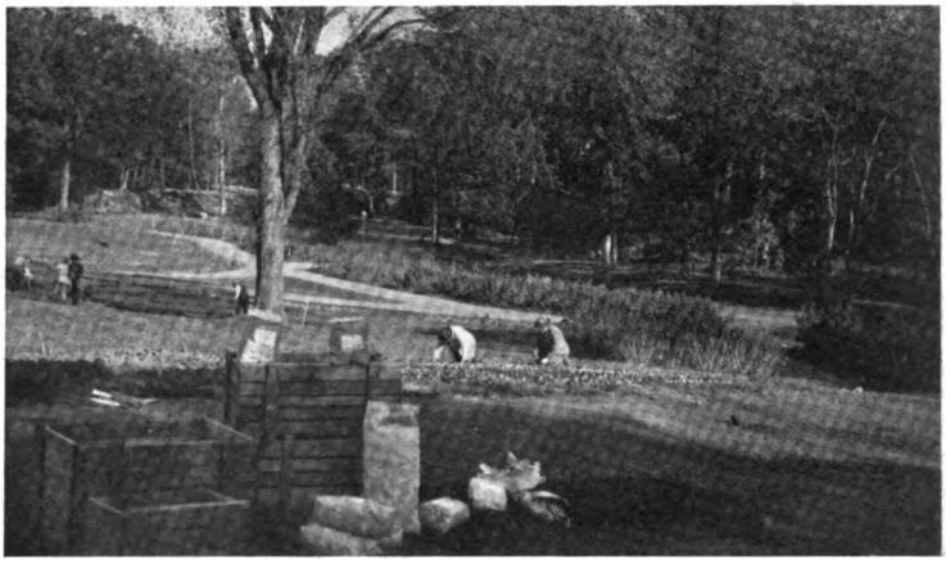
Regulation No. 9.—Prohibiting the importation of European buckthorn (Rhamnus cathartica) and Berberis vulgaris and all their hybrids and horticultural varieties.

Also all species and varieties of berberis and odostemon (Mahonia) susceptible to crown rust of oats and black stem rust of wheat, respectively, including:—B. amurensis, B. canadensis, B. Lycium, B. sibirica, B. aristata, B. ilicifolia, B. Nepalensis, O. Aquifolium. There are no restrictions on Berberis Thunbergi.

Potatoes are prohibited as a protective measure. Canada is free from potato canker as well as potato tuber moth and so precautions are taken to keep it free.—ED.]

A DAFFODIL COLLECTION IN THE UNITED STATES.

SIR,—The clouds have gathered and are closing in rapidly towards that black night when daffodils and certain other "miscellaneous bulbs" will no longer be allowed unlimited importation into these United States. January 1st, 1926, is the gloomy date. After then, only those who have been lucky enough to obtain permits from the Federal Horticultural Board in Washington will be able to import these bulbs. The importer must grow them for two years before he may sell or even divide them among his friends. His purpose in importing the bulbs must be approved at Washington: he must be undertaking scientific research in which he needs the plants, or have convinced the authorities that his "collection" is of such a nature that it is of horticultural or of scientific value to the country, and needs augmenting; or he must be going to use his plants to make money. Very little remains in this country on other than a commercial basis. It all seems a pity. We do need a quarantine, but not quite in this way. The amateur gardener is usually the one who desires the new, rare varieties, who makes a "collection," whether large or small, and it is he who insistently demands the good, new sorts until the growers here finally become aware that there is money in the better things. But few growers will handle newer kinds until they do become convinced of that fact and one can hardly blame them when they are to make their living from the plants they grow. Horticulture, as a general thing here, is in its infancy—too few know what is really worth planting; but we grow quickly here and we get so enthusiastic about a subject, and go at it with such a vim, that we should not be discouraged. The start was a good one. A few more slaps in the face like Quarantine 37 and our good start will have been of little use. What the amateur and the garden clubs must do now is to keep on learning what is worth having and to keep on demanding it; becoming more and more insistent. As far as daffodils are concerned, maybe the growers will become exasperated. They *can* grow bulbs here, but they will not be able to supply their customers at a price that any but the richest can afford. The question will be whether they will sell a very few bulbs at an extortionate price, like the farmer who leaves his peach crop on his trees rather than lower the peach market, or whether they will make more money selling a quantity of imported bulbs at lower rates. Once they become convinced that they will be able to sell enough cheap daffodils to make a larger income, they will convene in Washington, get a hearing and bang! off goes the insane quarantine based only on a commercial point of view and we shall have a sensible one where plants that come from infected districts will be excluded until the districts are shown to be free from disease. Of course, the commercial spirit will be under it all the same; but the result is what counts. Nobody objects to a commercial reason for anything that helps tend toward real betterment along lines entirely uncommercial. Fortunately, the gardening spirit is one accustomed to sharp set-backs, to looking to the future, to exercising a large imagination, and particularly is it so when planting bulbs. Those storehouses little show to the uninitiated what worlds of beauty they contain. Persistence is the rock bottom foundation of good gardening. Naturally, with such a sword of Damocles as this exclusion hanging over daffodil lovers, there is an agonising rush to get all the bulbs possible before the



THE PLANTING OF DAFFODILS AT THE NEW YORK BOTANIC GARDENS.

Digitized by Google

day arrives and the dealers here have been quite staggered by the onslaught. Next year no doubt, the demand will quite out-distance the supply. Among the collections augmented has been that of the New York Botanic Garden at Bronx Park, New York. Through the generosity of the Dutch Bulb Growers' Association, which made a gift of about thirty-seven thousand daffodil bulbs, and through purchases, using a fund subscribed to by garden clubs and individuals, over fifty thousand narcissi have been planted this autumn. The rare sorts have been put in beds, others "naturalised," and the whole concentrated in a portion of the grounds the nature of which is rolling, with out-cropping of rocks at one side, beautiful woodland on two others and a sunny meadow devoted to bearded irises, on the other. The planting was an interesting study from many points of view. The tools available for the work in the grass were varied. Over here we are not lucky enough to be able to get Barr's bulb planter, but one of them we did have. Other tools used were spades, a digging fork, a long and a short crowbar (light, and resembling huge chisels) and, of course, trowels. The ground was very hard in spots as the planting took place during a period of drought. The bulb-planter was most certainly the best tool and the spade the next best. The crowbars made good holes, but as the ground was simply pushed hard into the sides, many of them had to be filled with soil after the bulbs had been dropped in. The large trumpet daffodils, with the exception of the varieties Emperor and Fairy, were put in dug ground to give them a better start and a colour plan was made beforehand for the "wild" effects. It is hoped to increase the planting next year as there is plenty of room where the collection is located to spread out.—ETHEL ANSON S. PECKHAM, *New Rochelle, New York.*

PRUNUS SUBHIRTELLA VAR. AUTUMNALIS.

SIR,—I am surprised and disappointed at an omission in Mr. Bean's admirable little book, "Shrubs for Amateurs." The prunus mentioned above, which also seems to be called P. microlepis and P. Miqueliana var. Smithii (surely too many names for so small and delicate a thing). It is far less of a tree than Æsculus Paiva, Buxus sempervirens and Cotoneaster frigida, so that its size cannot be the cause of its exclusion. And as I saw it this morning, its long slender twigs covered from end to end with buds, of which a dozen have opened already to pearly white flower, while the rest are a store of delights to last us from now until March, I thought that, were I condemned to choose three shrubs, and rejecting all others cleave only unto them, Prunus subhirtella var. autumnalis should be one of the three. I might add that the year it came here it was planted in November and was blooming by January.—E. HUNTINGFIELD, *Halesworth.*

FRIENDS AND FOES OF THE GARDEN.

SIR,—Like your correspondent, W. Linders Lea, I read with much interest and pleasure Mr. Clifford W. Greatorex's article on our feathered "Friends." Although some birds admittedly do a certain amount of damage in the garden, I do not consider that any of them deserve to be called "Foes," for surely they earn a share! Here we feed the birds regularly all through the winter and are rewarded by a large and varied collection of visitors to our breakfast room window ledge; included in the list are thrushes, blackbirds, chaffinches, blue and great tits, starlings, and, of course, sparrows and robins. Personally, I consider that a garden without birds would be robbed of half its charm: imagine an early summer's evening without the song of thrush or blackbird! I sincerely hope that the time will come, in the not far distant future, when you may be able to include articles on birds as a regular feature of your valuable paper.—CECIL M. BAILEY.

SIR,—In the article, "Friends and Foes of the Garden," in the issue of THE GARDEN for October 25th, Mr. Greatorex writes of the dormouse as being non-injurious to the gardener's "valued plants." While this may be true of the common dormouse, there is one species, known as the "garden dormouse," which is capable of doing great damage to fruits in the garden. Some years ago these little animals raided the peach houses here, spoiling quite a number of the peaches and nectarines. I was puzzled somewhat at first as to the cause of the damage inflicted on the fruits, till I caught one one day mutilating a choice nectarine in broad daylight. They did not consume a fruit wholly, but sampled a number, usually selecting the best fruits. Needless to say every dormouse after that we came across was soon put out of existence.

In "Wood's Natural History," the author, writing on the Lerot, or garden dormouse, says: "It has derived its title of Garden Dormouse from its annoying habit of entering gardens and making sad havoc of the choicest fruit; for it is an animal of great taste, and makes its selection among the ripest and best fruits with an accuracy of judgment that may be highly agreeable to itself, but is sincerely execrated by the owner of the garden. It is particularly fond of espalier-trained fruit-trees, and is much given to devouring the peaches when they are just in their bloom of rosy perfection."

This species appears to be larger than the common dormouse, being 8ins. in length, including its tail, the latter species being rather more than 5ins. long. With regard to Mr. Greatorex's dictum *re* cats and their abolishment, after long experience in gardens with cats, and without cats, I should vote in favour of their retention, as I find the damage done in cat-less gardens by the creatures on which they prey is very great.—R. W. DEAN, *Audleys Wood Gardens, Basingstoke.*

THE ALPINE FLORA OF THE COL DU LAUTERET.

SIR,—Having had the pleasure, accompanied by my wife, of spending a week at the Col du Lautaret in Dauphiné, towards the end of July, 1924, I thought that perhaps a few notes regarding the alpine flora we saw there might be acceptable to those readers of THE GARDEN who might be described, not so much as "botanists," but rather "alpine plant lovers." We made the Hotel des Glaciers our headquarters and found everything quite comfortable for anyone who has a good working knowledge, as distinguished from book knowledge, of the French tongue. The higher alpine meadows, such as exist around there, want to be seen before they can be realised; in that they present certain alpines, and those not of the commonest, in an unlimited profusion. The writer had on at least three previous occasions obtained plants from nurserymen ostensibly of Campanula barbata, to find that one was defunct on arrival, the second on blooming turned out to be C. thyrsoides, and the third the true barbata, blossomed with him in the spring of this year; but both C. barbata and C. thyrsoides were in full bloom at the Lautaret, the former in thousands and the latter not uncommon. To see an alpine meadow glorified with the soft, yet distinctive blue of myriads of C. barbata is surely a "sight for gods and men." In all this abundance of the plant we did not once come across the white variety, or indeed any variation in colour of bloom worth recording.

We also saw thousands of Lilium Martagon: but here the variations in habit and colour seem worthy of remark. One form of the plant was characterised by the possession of a woolly down, particularly noticeable on the unopened buds of the inflorescence, which gave a very peculiar appearance, totally distinct from the other form with smooth buds possessing no down whatever. I should be pleased to know from any botanically inclined reader of THE GARDEN what name, if any, this sub-species or critical variety of L. Martagon possesses. We found that this variety has a more distinctive coloration of petal which appealed to me much more than that of the typical "smooth" variety, the colour of which is of a livid, unpleasant and undecided tone that somehow always reminds the writer of decaying flesh which is ruddy below, but with this colour marred by its surface tint. We searched among some thousands of these plants and were rewarded at last by finding a clump of about six bulbs, which, if not pure white, were at least an ivory white without taint of the other colour. Of these we took three without removing the others and carefully replaced the sod again, laying underneath it the few scales which had been displaced from the three bulbs removed. There is always some satisfaction to the writer in taking home to his own garden a bulb as distinct from a non-bulbous plant, because one has something tangible and substantial, something with a reserve of energy, which enables it to tide over the winter and await with certainty the resurrecting touch when the sun returns in spring in its strength. The most familiar and most showy plant of the Col du Lautaret is the "Oeillet du Lautaret" (Dianthus neglectus), and here, indeed, there is room and to spare for selection of more and yet more brilliantly-coloured forms. My wife and I wandered around the meadows day after day and each day we seemed to happen on blossoms of this plant more brilliant in colour than those of yesterday. We took a few and how they will colour their blooms remains to be seen in succeeding years, but it is to be feared that the colour will not be what it was on heights of the Lautaret. And now, Mr. Editor, that I may not trespass too much on your space, I shall cease to dwell on the beauties of the Lautaret, but if it be your will, and the will of the readers of THE GARDEN, I may perhaps on some future day describe the little plants we saw and loved at the Lautaret, at the Galibier, and at the pass of the Mont Cenis.—R. J. S.

ROSES: GUARANTEED BRITISH GROWN.

SIR,—The appeal made by The British Rose Growers' Association to growers of roses to buy only those which are delivered to the consignee bearing the seal of the Association is worthy of consideration and adoption. Every season one notices in our markets, and in auction rooms, trees offered for sale—often denuded of foliage entirely—that to an old grower show unmistakable signs of their having been exported. In the majority of instances, these trees after being planted in British soil do not last more than a few years, being unadapted to our soil and climate. As a grower of roses of many years standing, I am convinced that there is nothing like British roses for this country. Foreign grown trees lack vigour and continuity, without which it is useless planting. There is therefore no cheapness in them, and it is more remunerative in every way to deal with home nurserymen. More than half the foreign roses which I have seen planted in this country have but a brief existence when compared with home reared and grown trees. The seal which all firms of repute are now using, is a guarantee as to the *bona fides* of the article sold, and is a satisfaction to the buyer to know that trees sent him are more likely to flourish in his garden, because they are of British origin. The appeal has not come a moment too soon.—W. LINDERS LEA.

SIMPLE GARDENING

THE LAWN.

A BEAUTIFUL lawn—one well made and well attended to all the year round—adds very much to the general attraction of a dwelling-house. In towns and their suburbs, where green grass and foliage are so much appreciated, efforts to secure such are never regretted. But the attention given to lawns during the summertime will not result in a faultless lawn. The work done then is quite different from that required in the winter. I am sure that many readers, who pay very close attention to their lawns in the summer, neglect them in the winter. I do not refer now to the laying down of turves but to the general treatment of the established lawn. I do not advocate the placing of thick dressings of farmyard manure on the lawn. Where this has been done without regard to proportion I have seen the grass destroyed wholesale. All manure of this kind applied as a surface dressing should be well rotted and broken up rather finely. Equal bulk of good loam passed through a 1in. mesh sieve should be added and the two ingredients thoroughly mixed. One barrowload to a square rod will do much good. Where these cannot be obtained use 1 peck of old mortar rubble reduced to a powder and, one month later, a similar quantity of old, dry soot, respectively, per square rod. Wood ashes are good, too. If the above cannot be obtained, rake the lawn vigorously one day and brush it to and fro the following day. In every case roll the grass when it is fairly dry, not sodden.

GLOBE AND JERUSALEM ARTICHOKES.

Artichokes are rarely well grown. In the first place, they are planted in unsuitable soils and positions or in badly prepared ground. The plants will grow in nearly all kinds of soil—sandy, clayey and medium loam, doing best generally in the latter. But without good treatment the best is not obtained from the plants. When raising young stock of globe artichokes I always sowed two or three seeds in 3½in. pots filled with good loam and a little leaf-soil, retaining the pots in a cold frame till April, hardening and planting out at the end of May. This made a good beginning, as the plants grew strongly all summer without check. In the winter previous to sowing the seeds in February the ground was trenched and manured. Readers should do the work now if suitable ground has not already been prepared. A word also about the present treatment of established plants. If unprotected, these suffer in severe winters. All dead leaves and weeds should be cleared away, the soil loosened on the surface only, and dry strawy litter and fresh tree leaves, mixed for preference, packed neatly round each plant. It is time now to lift and store the Jerusalem artichokes. The large tubers should be stored just like potatoes and the medium-sized ones by themselves in readiness for planting again next March. After the crop is lifted the ground should be trenched.

PRUNING VINES.

I always like to have my vines pruned about Christmas Day; not later than the last day in December. As the daylight begins to lessen I cut back the end of each branch a few inches, thus ensuring more light reaching the basal buds on each branch, as these buds are important; those nearer the ends of the shoots are not as necessary to the next year's crop of grapes. By the end of December nearly all the leaves have naturally matured, fallen off or do fall when the rod is sharply rapped. Their functions are at an end. On each side branch, of the current year's growth the two bottom or basal buds should be taken great care of, as from one of these the next bunch of grapes comes. A sharp knife should be used to cut off the branch in preference to pruning scissors, as the cut must be a clean one, leaving a smooth end just beyond the bud and not

a jagged one. With the left hand hold the rod firmly while the cut is being made. The accompanying sketches show how young, nicely established and old vines should be pruned. The young vines should be pruned as shown at *a*, it is the right way to build up a strong rod eventually. On some rods shoots as shown at *b* grow, these should be cleanly cut out unless required to fill a gap. Prune the leader as shown at *c*, leaving 2ft. of young rod, *d*, and the side branches as shown at *e*. A main rod, *f*, bears side branches and spurs; cut off as shown at *g*, taking care of bud *h*; the one, *i*, is useless. An old spur is shown at *j*, *j*, the current year's branch is pruned at *k*, the bud, *l*, being rubbed out as soon as growth begins.

HOW TO PREPARE GROUND FOR GLADIOLI.

These lovely flowers were greatly admired last year, hundreds of thousands of them were grown in gardens large and small. Many were well grown, others showed lack of cultural skill. Undoubtedly much finer spikes, and individual flowers also, are the result of high cultivation and constant watchfulness as the spikes develop. Some corms are started in pots and planted out later in the season where the soil is clayey and cold; the majority are planted in the open border during April and early May. I much prefer to plant in the border, even where the soil is stiff, if it can be duly prepared. It is a mistake to defer soil treatment to planting time. Begin now. The best way is to commence on the selected plot as if real trenching work was being done. The subsoil should be left in the bottom, but thoroughly broken up, and the surface portion turned over in as lumpy a condition as possible. It is really wonderful how mellow such clayey soils will become by the end of March. The exposure to wind, rain and frost pulverises the lumps so they crumble almost to powder. I may state here, for the benefit of the inexperienced, that in gardens where organic manures are not available, hop manure, mixed with the soil at the bottom of the trench, will prove very beneficial. The trenches should be made 9ins. deep early in April, the hop or organic manure used, and a nice sprinkling of bone-meal added to the top soil when the trench is filled. With sand placed round each corm when planted, growth will be free and strong.

WATER GARDENS.

Bog and waterside plants are, in suitable positions, always very restful and attractive. One would think that such plants, when nicely established, would take care of themselves—thrive without any further attention as it were. Some of them—the strongest—will do so, but we wish to maintain the balance so as to give the weaker, but none the less beautiful, plants their chance to grow freely. An ordinary plank will enable the workman to approach the plants in certain cases, but in others, where there is deeper water, the plank should be nailed to a strong empty box. These precautions are necessary for bog gardens, but for streams and similar places water-tight boots are generally sufficient. Coarse weeds should be dredged out with roots and mud attached. Portions of very strong-growing plants can be detached and the slips planted elsewhere if required. At the sides of streams hardy ferns look charming always, and roots may be planted there, re-arrangements made, and foreign matter cleared away from all specimens so that there will be nothing to interfere with the growth of the new fronds in due course. The present is a suitable time to make good any landslips, tiny or serious, near streams and ponds, and to rectify deficiencies.

GEORGE GARNER.

CHANGES IN PLANT NAMES

BY F. A. HAMPTON.

SINCE almost all our garden plants were introduced from abroad, and came to us with names more or less strange, their vocabulary provides a good general picture of the kind of changes that foreign words undergo as they are gradually absorbed into the language and moulded into conformity with it. The list of garden plants is continually growing and their names are often uncouth to those who have most to do with them, so that the most frequently used are likely to undergo the regular philological changes in the process of their naturalisation, and as the process is going on around us the interest of these changes is not wholly antiquarian.

The simplest way of adopting a foreign word is, naturally, to give it an English pronunciation and then to spell it phonetically. This happened to the French *pensée*, which became first *paunsie* and finally *pansy*; the English tendency to place the accent early in the word, and rather heavily, leading to a blurring of the final *ée* into an indeterminate *y*. A similar shift of accent makes *ándrosaise* a popular pronunciation of that awkward word *androsace*.

One rather curious result of a change of pronunciation is the obliteration of the personal name in those plants that are called after distinguished botanists and others, so that Leonard Fuchs is hardly to be remembered in *fuchsia* nor Dahl in *dahlia*.

When a word has been a long time in circulation it tends to become softened in pronunciation and, as it were, "run together"; thus, on tracing back *germander*, we find successively the late Latin *germandra*, the late Greek χαμανδυά (chamandrya) and, ultimately, the classical Greek χαμαιδευς (chamædrys), *i.e.*, "ground-oak"; in the official nomenclature the popular "germander" is re-minted as a specific name, *Veronica Chamædrys*. A simpler case of "running together" is *damson*, which has the same origin as the damask rose and was first known in England as the "damascine plum."

As another result of long use, words become shortened by syllables dropping off, *athanasia* (immortality), coming through late Latin as *atanesia*, becomes eventually *tansy* in English. This method of shortening seems more popular nowadays than compression for dealing with long plant names; rhododendron is being familiarised into "rhodo," and the future of chrysanthemum seems to waver between "mum" and "chrysant," with a bias towards the former. Possibly the initial *a* was the more readily dropped from *atanesia* because it looked like the indefinite article, a factor that may be influencing the fate of anemone, which the street sellers in London are turning into "nemony" and, with a transposition of consonants, into "nenomy."

The definite article has sometimes had a considerable effect on the form of a word by becoming incorporated with it, especially in the case of words coming into the language through Arabic and bringing with them their definite article *al* (the). In the case of Koran, which was for a long time written "Alcoran," the meaning of the first syllable has been recognised and it has been dropped; but in many Arabic words of earlier introduction the article has been firmly welded into the structure of the word and become inseparable. A good example is found in that far-travelled word *apricot*, which begins as πραικόκιον a late Greek word corresponding to the late Latin *præcoquum* (*pomum*), *i.e.*, "early apple." In the Spanish Peninsula *præcocion* became, in Moorish Arabic, *burquq*, and appears, with the definite article *al* prefixed, as *albricoque* in Portuguese and thence in Elizabethan English as *apricock*. The tree itself is said to have an origin even farther afield, in North China, though Linnæus gave it the official name of Prunus Armeniaca.

The first syllable of *alkanet* ("the henna") and *artichoke* ("the cardoon") is a relic of the Arabic *al*, and it has been suggested that *daffodil*, which is certainly derived from asphodel, may possibly owe its mysterious initial *d* to the Dutch or Flemish definite article *de*, much as "doolay" in the Army French of the last war meant simply "milk."

Perhaps the most subversive change that affects imported words is that due to a tendency to force them into line with native words of similar sound, and just as our method of dealing with a new phenomenon is to analyse it into terms of the already known and find a pigeon-hole for it in our past experience, so, in dealing with a strange word, we try to analyse it into something familiar and meaningful, but if this is not possible there is a strong tendency, especially in the living, shifting forms of popular speech, to give the word a twist in order to fit it in some category. So the word asparagus, that had no meaning for those without classical learning (and very little for anyone else), became "sparrow-grass," and, as Weekly points out in the "Etymological Dictionary of Modern English," this was the polite form up to the nineteenth century, quoting from "Walker's Pronouncing Dictionary" (1791) "'Sparrow-grass' is now so general that asparagus has an air of stiffness and pedantry." Another typical example is the Greek καευόφυλλον (caryophyllon), a "clove" (literally "nut-leaf"), which, after being worn down into *girofle* (Norman French), sported into a great number of forms after crossing the Channel, appearing in Middle English as gilofer, gilliver, gerafloure, etc., and finally settled down, under the attraction of the word "flower," as *gilly flower*, with a sporadic further perversion into "July flower." The original form is restored in the official name "Dianthus caryophyllus" (clove pink).

This process of assimilation, or the like one of folk-etymology, is still actively at work with strange plant names, and we record occasional brilliant formations, such as "sigh-forthia" (Forsythia) and "China doxies"; but, for the most part, the throes of change are unobserved since they occur in the spoken, not the written language; yet it is a pity that they should go unrecorded, both for the sake of future students of the language and because, where a new English name is called for, a study of the fluid elements of the language might contribute to the success of the coining. It may be urged that our new garden plants have already their adequate official names and that English ones are neither necessary nor desirable; this for the most part is true, yet there are exceptions, such as a certain exquisite yellow pæony (in the absence of a book of reference its name is unwritable) that suffers at present under the unpronounceable obscurity of a Polish eponym or the undeserved humiliation of "Miller's Whiskers."

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this*. It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

PLEASE REMEMBER TO MENTION "THE GARDEN" WHEN ANSWERING ADVERTISEMENTS.

THE FARMERS' CHELSEA

ALTHOUGH the Smithfield Club Show at the Agricultural Hall, Islington, is the Mecca of the farming world, where keen experts go primarily to inspect the fatted cattle, sheep and pigs, there is also much of interest to gardeners. But this is not on the ground floor, where are stalled the King's first-prize animals, of perfect proportions and handsome appearance, but in the Gallery with the gargantuan feeding roots. It is on such occasions as this that those of us who consider such great seedsmen as Carters of Raynes Park, Dicksons of Chester, Fidlers of Reading, Harrisons of Leicester, Kings of Coggeshall, Suttons of Reading, Toogoods of Southampton and Webbs of Stourbridge, in relation to garden seeds, realise how vast also is the business done by them in agricultural seeds, and that equal care is taken in breeding and selecting strains of seeds suitable for the farmers' purposes.

It would be difficult to imagine any more imposing exhibit of roots than the roof-high displays of perfectly symmetrical mangolds of enormous size, flanked by equally high-grade swede turnips of quite a different strain from those we grow in gardens. A similar difference is noticed in the cattle carrot of pale, almost parsnip appearance, and in the enormous size of the parsnips grown for the feeding-trough. While, with these types, size is an important factor, size alone is not the end and aim of the leading seedsmen. Sheer size is too often accompanied by an excess of water content, so the skill and knowledge of the breeder is directed towards the production of a root of large size combined with small water content.

What can be achieved by the plant-breeder is well illustrated by the crosses between mangolds and the sugar beet which were to be seen among the magnificent roots shown by Messrs. Sutton and Sons. The object of the crosses is to obtain a feeding root containing a greater proportion of sugar than is present in the mangold. A "well bred" mangold will contain somewhere about 6 per cent. of sugar, while the sugar beet has about 16 per cent. Crosses between the two roots have given rise to hybrids in which a goodly proportion of the greater sugar present in the beet has been combined with the bulk and, what is very important, the masticable flesh of the mangold. The sugar beet itself is so hard, almost woody, in texture as to be quite unsuitable for ordinary feeding purposes—any serious attempt by cattle would soon ruin their teeth. By using Prize-winner mangold a hybrid containing nearly 11 per cent. has been evolved, while the sweeter Golden Tankard mangold has given a hybrid with over 13 per cent. of sugar. In both instances there is a notable advance on the 6 per cent. sugar content of the mangold itself. Already part of the problem is solved: a masticable feeding-root containing a relatively large proportion of sugar has been obtained: but, as was quite anticipated, its yield per acre is distinctly less than that of the mangold. So that the work must be continued, and, remembering what Messrs. Sutton and Sons have done in other directions, we have no doubt as to the ultimate result.

As one would expect at such a show, potatoes were a very important feature of the garden exhibits. Messrs. Fidlers confined themselves to these tubers, of which they had a large variety of the best sorts. Majestic, Resistant Snowdrop, Tinwald Perfection and Witch Hill Early are the names of only a few of their well known potatoes. Messrs. Sutton and Sons included their new Ben Cruachan, a heavy-yielding main-crop of handsome appearance which was, at Ormskirk, awarded the Lord Derby gold medal for the finest variety immune from wart disease. Ben Lomond, a second-early kidney of great cropping powers, is another of their potato novelties. Almost a colour scheme in tubers was seen at the stand of Messrs. Carter and Co., who showed most shapely, purple-tinged tubers of Catriona, Di-Vernon and Sedgecote Purple; while dishes of Red King were prominently shown by Messrs. Webb and Sons. Messrs. Little and Ballantyne had fine tubers of Red King, Ally and British Queen.

Next in importance came carrots, such as Red Elephant and Scarlet Perfection from Raynes Park; Prize-winner, Defiance and Standard from Stourbridge; all of them as shapely as though moulded. Parsnip Toogood's Improved Marrow, Carter's Maltese, Globe Beet of value for shallow soils, Brussels Sprouts, leeks and splendid onions were all worthy of the exhibitors and the occasion. Many firms showed sacks of pea seeds, and Messrs. Carter and Co. had some large photographs of their new Giant Stride dwarf pea, which is the result of crossing Quite Content with a dwarf sort. The new variety is said to grow about 18ins. to 2ft. high, and the photographs showed how freely it cropped.

The only display of fruit was a very bright collection of apples from Messrs. W. Seabrook and Son, who had brilliant dishes of King of the Pippins, Excelsior, Wealthy, Bismarck, Monarch and Newton Wonder, among many others. They also showed their new late dessert apple Mr. Prothero, which is in season from March onwards.

In an annexe of the Gallery there were to be found the stands of manures and spraying materials. Messrs. Prentice Brothers showed their specialities put up in attractive tins and cartons—Tomorite, which gives greater colour to tomatoes; Vegerite, for growing better vegetables; and many other special manures were represented. Messrs. Fisons had their well known brands of fertilisers: Rito, which has now long been known and valued, was also there, and so were samples and statistics of the Sulphate of Ammonia Association. Cooper's valuable fruit tree washes and the Four Oaks Sprayers and compounds also attracted a deal of attention.

WINTER WASHING OF FRUIT TREES

THE necessity for hygienic methods in the garden is better understood than it used to be. Yet we have much to learn in this matter, particularly in respect of fruit culture. Those of us who occupy our time as horticultural teachers and advisers realise the need of more education in plant hygiene.

During the present season of the year, for example, we see a large number of fruit trees which are wreathed in mosses and lichen. Such trees are a menace to successful fruit production. The mosses and lichen form an excellent harbour for hibernating insects and a safe place of deposit for insects' eggs. In addition, the proper respiration of infested trees is hampered. There is every reason for killing the mosses and lichen. There is no good reason for allowing them to live. Fortunately, we have specifics at our command which are fatal in their effect upon extraneous growths. I would appeal to fruit-growers to apply one of them between now and the middle of February. The sooner the better, because there is an element of danger in winter washing after the sap begins to ascend.

I have submitted several sprays to a careful test, after which I pin my faith to the old-fashioned caustic alkali wash. It has proved the best with me. Following is the formula: Caustic soda (98 per cent. purity), 1lb.; caustic potash (80 per cent. purity), 1lb.; agricultural treacle, ¾lb.; and water, 10 gallons. The ingredients should be assembled with care. First dissolve the potash and soda separately in two wooden vessels, afterwards mixing the solutions. Now pour in the treacle and stir the whole thoroughly. The wash is ready for use when it has been made up to 10 gallons with water.

It is always advisable, in order to assure equality of treatment, to choose a dry and calm day for the actual application. All the aerial parts of the trees should be treated with a mist-like spray. There are, of course, numerous machines at easy prices suitable for the work. It is good practice for the operator to wear old clothing and woollen gloves. The caustic elements of the wash are not kind to human skin and garments. Some gardeners may not be able to spare the time for mixing a winter wash. Others may fear the danger of complications in the handling of caustic chemicals. To such I would like to recommend the Woburn Winter Wash, which may be purchased from any reliable horticultural sundriesman. It should be used in accordance with the vendors' instructions. This wash emerged from my own test with honour. The effect upon mosses and lichen is quite fatal, though not so rapid as in the case of the specific first noted.

GEO. H. COPLEY.

CATALOGUES RECEIVED.

Messrs. Sutton and Sons, 1925.—Amateur Guide in Horticulture and General Seed Catalogue.

Messrs. Sutton's name is so well known throughout the whole horticultural world that it is almost unnecessary for us to draw attention to the issue of their already well known annual guide. This volume, which runs to 200 pages, is full of practical information of great value to the amateur, in dealing with the production of vegetables and flowers from seed. All those beautiful subjects which stand foremost in the public favour, such as asters, campanulas, gloxinias, begonias, godetias, larkspurs, etc., are given prominence. One realises what an endless variety one can have in the garden if one makes a wise selection. Numerous excellent illustrations in black and white are to be found throughout the catalogue. Coloured illustrations are also to be found and while some are good, others do not give the reader a true idea of the subject illustrated. From flowers one goes on into the more economic section of the catalogue dealing with vegetable seeds, in their infinite varieties—a large amount of space being devoted to potatoes. Much serviceable information is given on lawns and their upkeep, while a new feature is a number of pages given over to horticultural tools and general sundries.

Messrs. Sutton's record at the horticultural exhibitions throughout the past year is one to be proud of—having won no fewer than thirty gold medals for the excellence of their flower and vegetable seeds. These exhibits alone are of educational value to the ordinary gardening public.

As we have remarked, there are numerous illustrations, over 200 reproductions from photographs and many are decidedly effective. The catalogue is well printed throughout and shows every care in compilation. We understand that it will soon be sent out to all regular customers and those who wish to have it can apply direct to Messrs. Sutton's and Sons. It is certainly one which should be obtained by all those interested in gardening.

Messrs. Laxton Brothers, Bedford.—Fruit Trees and Small Fruits.

It may be mentioned that Messrs. Laxton Brothers have now ample supplies of their new late dessert apple, Laxton's "Superb," which gained the R.H.S. award of merit in 1919. It is the result of crossing Wyken Pippin and Cox's Orange Pippin, and it is believed that it will take the place of Cox's Orange Pippin. The fruit is certainly equally good in flavour and rather larger than a Cox's. It follows Cox's in season and keeps well into March, which makes it a valuable variety. The tree is a strong grower and very prolific. It should make an excellent dessert fruit, and is one which merits a trial from all those interested in fruit culture.

Fisher, Sons and Sibray, Limited, Royal Nurseries, Handsworth, Sheffield.—Hardy Trees and Shrubs.

FOREIGN.

Vilmorin, Andrieux et Cie., Paris.—Seed Catalogue of Hardy Trees and Shrubs.

V. Lemoine and Son, Rue de Montet 136-142, Nancy.—Trees and Shrubs, and Greenhouse Plants.

BOOKS RECEIVED.

"The Story of My Ruin," by Mrs. Marion Cran, F.R.H.S. (Herbert Jenkins, Limited, 3, York Street, London, S.W.1, price 10s. 6d net.)

"Gardening in Sunny Lands," by Mrs. Philip Martineau. (Richard Cobden-Sanderson, 17, Thavies Inn, London, price 15s. net.)

British Florists' Federation.—The Market Floral Committee of the B.F.F. met in Monro's Salerooms on November 17th, and Mr. D. Ingamells presided in the unavoidable absence of Mr. W. E. Wallace. A provisional first-class certificate was awarded to Chrysanthemum Harmony, a fine reflexing Japanese variety of rich bronzy-red colouring. This was exhibited by Mr. H. Shoesmith, Guildford. Some blooms of another variety of large exhibition size were submitted, but the committee did not consider itself justified in making awards when exhibition blooms only were submitted, as its principal business is to consider the merits of flowers from a market point of view.

Rose Trials at Wisley.—The special committee appointed by the Council of the Royal Horticultural Society to judge the roses under trial at Wisley has now reported the results of their first year's visits. The committee consists of the President of the Society, the Right Hon. Lord Lambourne, P.C., V.M.H., Chairman (Mr. W. Cuthbertson, J.P., V.M.H., acting in his absence), Mrs. Wightman, Dr. Lamplough, Dr. Williams, Messrs. Coutts, Darlington, A. Dickson jun., Easlea, Hay, Holland, Prince, Poulsen, Pernet-Ducher, Taylor and Wettern. The committee met several times at Wisley during the year and assessed the garden value of the roses on each occasion. They have to point out, however, that no awards are recommended until a rose has been growing in the garden for at least two years, and that some varieties which will doubtless attain the highest award in future years are recommended here a lower award or altogether omitted because they have not been seen at their best on the occasions of the committee's visits, or have not been sufficiently long in the trial garden to enable the committee to come to a considered judgment of their behaviour there. It should be noted that judgment is based solely upon the behaviour of the rose in the garden; it is judged from the standpoint of its value for garden decoration. The committee wish it to be clearly understood that the omission of a rose from the award list on this occasion is not to be taken as condemning it as a garden rose.

The Council of the Royal Horticultural Society has instituted a special award for roses adjudged of value in these trials, to be called the Wisley Rose Award. It is of two grades, viz., Class I and Class II.

The following awards have been made to roses by the Council of the Royal Horticultural Society, after trial at Wisley:

Double and Semi-double Varieties.

Award Class I.—Hawlmark Crimson, raised and sent by Messrs. A. Dickson, Newtownards; Christine, raised and sent by Messrs. McGredy, Portadown; Red Letter Day, Mrs. Wemyss Quin and Betty Uprichard, raised and sent by Messrs. A. Dickson.

Award Class II.—Lady Pirrie, raised and sent by Messrs. Hugh Dickson, Belfast; Lamia, raised and sent by Messrs. Easlea, Leigh-on-Sea; Mme. Jules Bouché, raised by Mr. J. Croibier, sent by Messrs. A. Dickson; Mrs. Hornby Lewis, raised and sent by Mr. Elisha Hicks, Hurst; Miss Dorothy Mocatta, raised and sent by Mr. F. Spooner, Horsell, Woking; Mrs. Bryce Allan, Mrs. C. V. Howarth and Chrisse Mackellar, raised and sent by Messrs. A. Dickson; Bedford Crimson, raised and sent by Messrs. Laxton, Bedford.

Dwarf Polyantha Varieties.

Award Class II.—Crimson Orleans, raised and sent by Messrs. Laxton; Edith Cavell, introduced and sent by Messrs. Cutbush, Barnet; Yvonne Rabier, raised by Messrs. Turbat, Orleans, and sent by Messrs. Cutbush; Mrs. W. H. Cutbush, raised by Messrs. Levavasseur and sent by Messrs. Cutbush.

Single Varieties.

Award Class II.—Pink Delight, raised and sent by Messrs. Laxton.

HOLLY THROUGH THE AGES

IN early times there was hardly a plant that had not some magic property or other. They were imaginative in those days and were not averse to trying experiments. The holly had more than its fair share of magical properties. In Pliny's time it was used as a preventive against lightning, although on what grounds I have been unable to find out. Its flowers caused waters to freeze. If a staff of its wood was thrown at any animal, even if it fell short of touching it, the animal was so subdued by its influence that it returned and lay down beside it. This must have been a particularly useful property, which it is a pity the holly no longer possesses. Also all witches had a strong objection to holly.

The use of holly as decoration at the New Year goes back deep into pagan times; in fact, so much was it bound up with pagan rites that the early councils of Christians forbad its use at Christmas. But later, either because of its decorative value or because of the absorption of old customs into the Church, it came into use again. Here is a quotation which shows the part holly played in the seventeenth century: "So our churches and houses decked with bayes and rosemary, holly and ivy, and other plants which are always green, winter and summer, signify and put us in mind of His Deity, that the child that now was born was God and man, who should spring up like a tender plant, should always be green and flourishing, and live for evermore."

I have also come across two carols on the holly which are worth giving in full. The first is from a manuscript of the time of Henry VI:

Nay, Ivy! nay, it shall not be I wys;
Let Holy hafe the maystry, as the maner ys.

Holy stond in the Halle, fayre to behold;
Ivy stond without the dore; she ys full sore a cold.

Holy and hys mery men they dawnsyn and they syng,
Ivy and hur maydenys they wepyn and they wryng.

Ivy hath a lybe; she laghtit with the cold,
So mot they all hafe that wyth Ivy hold.

Holy hath berys as red as any Rose,
The foster the hunters, kepe hem from the dos.

Ivy hath berys as black as any slo;
Ther com the oule and ete hym as she goo.

Holy hath byrds, aful fayre flok,
The Nyghtyngale, the Poppyngy, the gayntyl Lavyrok.

Good Ivy! what byrdys ast thou!
Non but the howlet that kreye "How! How!"

The second is later:

Here comes holly that is so gent,
To please all men in his intent.
Allelujah!

Whosoever against holly do cry,
In a rope shall be hung full high.
Allelujah!

Whosoever against holly to sing,
He may weep and his hands wring,
Allelujah!

Yet parallel with this use of the holly for decoration at Christmas you still find traces of it in relics of old pagan rites. As late as 1779 a writer in the *Gentleman's Magazine* describes a scene he witnessed in an East Kent village. He says: "Mr. Urban, Being on a visit on Tuesday last in a little obscure village in this county, I found an odd kind of sport going forward: the Girls, from eighteen to five or six years old, were assembled in a crowd, and burning an uncouth effigy, which they called an Holly-Boy, and which it seems they had stolen from the Boys, who, in another part of the village were assembled together, and burning what they called an Ivy-Girl, which they had stolen from the Girls: all this ceremony was accompanied with loud huzzas, noise and acclamations. What it all means I cannot tell, although I inquired of several of the oldest people in the place, who could only answer that it had always been a sport at this season of the year." The burning of effigies was sometimes connected with May Day celebrations, but the burning of the Holly-Boy took place in February, which makes it difficult to assign a reason for it, unless it personified the passing of winter.

It will be seen from these few notes the importance of holly throughout the ages both from the point of view of decoration and for its supposed magical properties.

HOLLIES

BY W. J. BEAN.

EVERYONE IS FAMILIAR WITH THESE ORNAMENTAL WOODY PLANTS SYMBOLICAL OF THIS SEASON OF THE YEAR, BUT ARE PERHAPS NOT SO WELL ACQUAINTED WITH THE NUMEROUS VARIETIES WHICH ARE TO BE FOUND.

THERE are between 250 and 300 species of holly known and they grow wild in many parts—both tropical and temperate—of the eastern and western hemispheres. Over twenty species have been introduced from abroad that can be grown in the open air, yet our native species, Ilex Aquifolium, remains very much superior in size, beauty and adaptability to any or all of them. It is late in the day to preach the virtues of the holly, and at this season, perhaps, sentiment may influence one's judgment; but of all evergreens it is, in my opinion, the most useful. As a hedge plant in or near towns it is unrivalled, although some will argue that in country districts the yew is equal or superior to it. But to my mind it is always brighter and more cheerful and, on account of its prickly nature, it is not so easily broken through, nor is it dangerous to browsing cattle and horses, as the yew undoubtedly is. Large, well grown hollies with their glistening foliage and red berries make in themselves an admirable feature for any garden, providing shelter in winter and spring and making the best of all backgrounds for early-flowering trees that blossom on naked branches. The holly, if not crowded, naturally keeps furnished to the base and this gives it a special value as a wind-break and for stopping ground draughts. There are numerous trees in Britain between 50ft. and 70ft. high.

Ilex Aquifolium has developed very many varieties under cultivation and there is now a large selection of yellow and white variegated ones, others varying much in habit—tall, dwarf, compact and weeping — and others showing great differences in size and character of leaf. But hybridity also enters into the matter. Although it has been the common practice to put all the forms of garden holly under I. Aquifolium, there is no doubt that many of them are partially descended from I. balearica, a species native of the Balearic Isles. This has larger, broader leaves than our British holly, thicker in texture, less spiny and of a duller green and the garden forms that show more or less of these characters, such as nigrescens, altaclarensis, Hendersoni, Hodginsii, Mundyi and Wilsoni, have inherited them from the Balearic species. All these are fine varieties, some of the best, indeed, of the green-leaved ones.

ILEX ALTACLARENSIS ONE OF THE NUMEROUS GARDEN FORMS.

SILVER HOLLIES.

Of the white—or so-called silver—variegated hollies with the white at the margin of the leaf, I do not think there is any one better than Handsworth New Silver, with its long, rather narrow leaves very dark green in the centre and very distinct margin of white. Of about equal value is Silver Queen with broader leaves than the other, not so many spines at the edges and a broad well defined margin of white. There are, of course, numerous other varieties with this type of variegation, but for most gardens these two will suffice.

Another but much smaller group of silver-variegated forms have the margins green and the centre of the leaf creamy white. So far as I know, none of them is better than Silver Milkmaid, with its large blotch of creamy white in the centre.

GOLDEN HOLLIES.

Of the considerable number of garden varieties with a yellow or golden marginal variegation, the well known Golden Queen is, for vigour of growth and high colouring, perhaps unsurpassed. Often the entire leaf is yellow. In spite of its name it is a male and never bears fruit. Another, called Madame Briot, is very ornamental; the area of yellow colouring on the leaf varies much in size; sometimes it is reduced to a narrow marginal line, sometimes it covers the whole leaf, but it is always rich and among the most effective of its group. The variety known as Waterer's has, apart from its rich colour, a special value in its close compact habit and comparatively slow growth. I have known a plant for over thirty years which has in that time only increased in height some 3ft. or 4ft. This quality makes it useful in formal arrangements where but little clipping is necessary to keep it to the required shape. Naturally, it grows almost as much in width as in height, and the spines on the leaf margin are few or altogether absent. Another compact, low-growing holly of distinct value is scotica aurea, which appeared as a sport on ordinary scotica in the Cheshunt Nursery. Like the green type, its leaves have no spines.

As in the silver-variegated varieties, there is a companion group with green margins and a central patch of colour; best known among them is Gold Milkmaid, or aurea mediopicta, a superior form of which has been given the additional name of latifolia. Both groups of central variegated hollies have a tendency to "revert" and produce wholly green shoots, which tendency is not apparent in the marginally variegated ones. These green shoots have to be cut out.

GREEN HOLLIES.

Mention has already been made of the best of the broad, duller green-leaved varieties descended, in part at least from I. balearica. Of those derived purely from I. Aquifolium I have always considered camelliæfolia the best. Its leaves have all the darkness and glitter of the common holly, but they are up to 4ins. or 5ins. in length and 2ins. to 2½ins. in width, but little undulated and with few or no spines. The habit is vigorous and naturally tall and elegant. Marnockii is of the same character, but not, in my experience, so good. Scotica is a dwarfish, slow growing one with no spines on the leaves.

The yellow-berried holly, fructu-luteo, originally found in a wood near Wardour Castle in Wiltshire long ago, does not

Digitized by Google

differ in habit or shape of leaf from common holly, but the fruits are very distinct in their good yellow colour. On dull November and December days they show up more effectively than the common red ones.

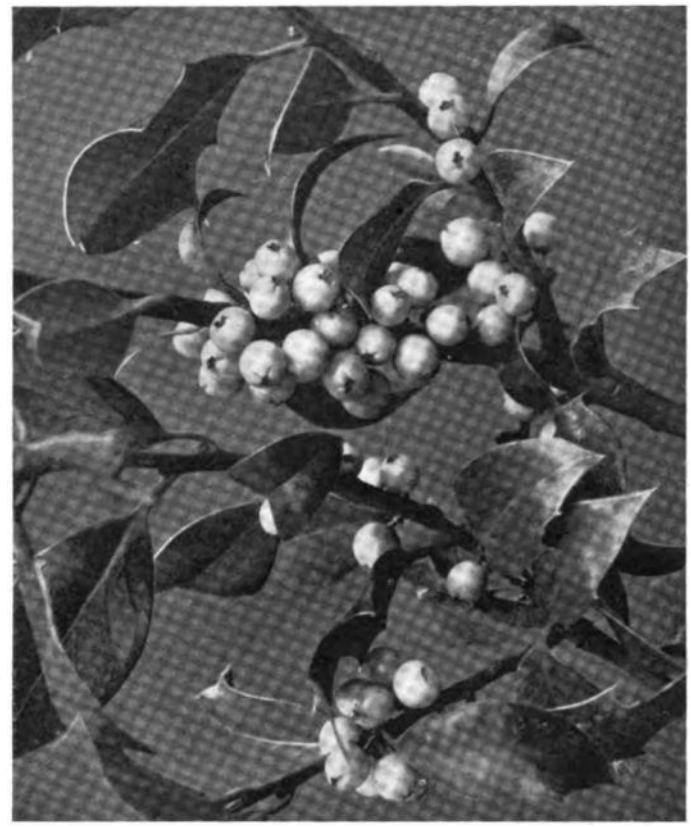
There is a group of hollies with small leaves and a dwarf habit, including myrtifolia, recurva, microphylla and handsworthensis, all with very spiny leaves ¾in. to 1½ins. long. They are worth bringing to notice for situations where dwarf, compact evergreens of slow growth are desired.

As has been the case with nearly all long cultivated trees, the holly has developed pendulous branches or "weeping" varieties. The weeping holly grows very slowly in height if left to itself and, to get increase in stature, shoots about the middle of the tree have to be lifted and staked upright. There is a weeping form of Golden Queen and one with silver variegation known as "Perry's Weeping."

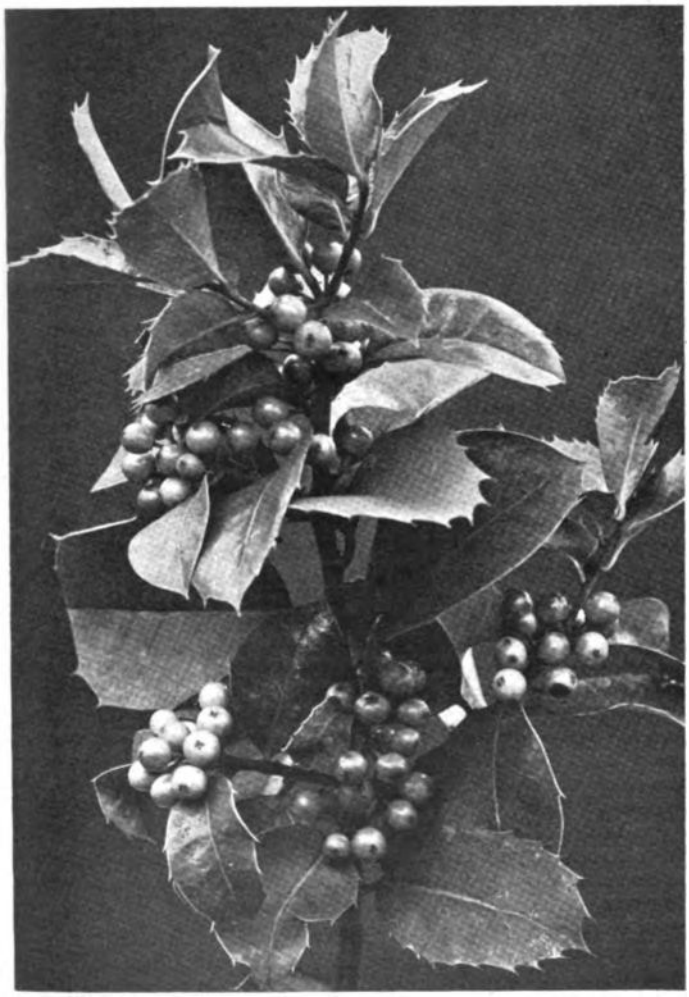
Lastly among garden varieties come the freaks. Conspicuous among them are the "hedgehog" (ferox) group, with numerous spines on the humped upper surface of the leaves; besides the green, there are forms with yellow and white variegation. Crispa has curiously twisted leaves with few or no spines; crassifolia has extraordinarily thick, leathery, narrow leaves with large triangular spines; hastata has small twisted ones with disproportionately large spines. The best looking of these curious forms are latispina with broad twisted leaves up to 3ins. long and few spines, and monstrosa, of a similar type but much more spiny.

SPECIES OF HOLLY.

While, as I have already remarked, I do not regard any holly from abroad equal in value to our native one, still less to the best garden forms, there are some species very well worth cultivation for the sake of variety. Best of all of them, I consider, is I. cornuta, introduced from China by Fortune as long ago as 1846, a very distinct and handsome species with curious leaves 2ins. to 4ins. long, rectangular in main outline, a large spine at each corner and others between. This is an evergreen of rounded shape 8ft. or more high, usually wider than it is tall, its foliage having the dark green lustre of the common holly.



ILEX FRUCTU LUTEO WITH ITS EFFECTIVE YELLOW BERRIES.



A HANDSOME GREEN-LEAVED HOLLY, ILEX WILSONI.

A newer Chinese species introduced by Wilson in 1900 is I. Pernyi. It also is a dark, glossy-leaved holly, but with leaves much smaller than those of cornuta. In habit, too, it is quite different, being slenderly pyramidical; altogether it is well worth a place. As to I. Fargesii, also from China in 1900, I have never yet seen it in a condition that would justify one in recommending it to any other than those who like to make collections. Its leaves are dull and uninteresting and its habit thin. The American holly, I. opaca, also has dull green leaves, but grows better; still, it is far behind our native species as an ornamental evergreen. I. dipyrena, the Himalayan holly, is the best dull-leaved species and makes a densely furnished and quite handsome tree.

Quite different from any of the evergreen hollies hitherto mentioned is I. crenata from Japan. It is a stiff, small bush with leaves ⅛in. to ¼in. long and has black fruits. Its variety Mariesii is the daintiest of all hollies, having roundish leaves about ¼in. wide and growing so slowly that it takes several years to become 1ft. high. A suitable shrub for the rock garden.

Deciduous hollies are quite numerous, but most of them are tender. The only ones that deserve mention here are I. verticillata from North America and I. serrata (syn. Sieboldi) from Japan. The American one succeeds the better in this country and when bearing its great crops of bright scarlet berries is very handsome indeed. The Japanese one has berries of the same colour but scarcely so bright. Both are unisexual, so that it is desirable to grow them in small groups with, say, one male to four or five female, giving the latter front places.

CULTIVATION.

Hollies are by no means fastidious as to soil, growing well in sandy, clayey, peaty or calcareous soils; but like most trees and shrubs, they give their best when grown in a deep, well drained loamy soil of good quality. In a poverty-stricken soil, like that of so much of Kew, top-dressings of manure and bone flour are needed to keep them up to the mark. The only matter regarding their cultivation that really needs discussion is transplanting. If a transplanting machine or other means of transporting plants from one place to another with a large

Digitized by Google

ball of soil is available, they can be moved at any time between September and May. It is with plants whose roots are shaken practically free from soil that difficulties arise. It is almost impossible safely to transplant large vigorous bushes in this way. It is only really safe to transplant either in late September or May. Such plants should be watered if dry weather ensues, and it is a great help if a sheet of canvas can be thrown over them till signs of growth become apparent. Transplanted hollies which were in vigorous health before moving have their chances of survival increased if the leafy growth is reduced.

GARDEN DESIGN: A SMALL GARDEN

IT is not fully realised to how great an extent the resultant beauty of a garden is dependent upon the correct subdivision of the whole area of the ground into its separate parts. Any garden, small or large alike, may be nothing but a more or less pleasing assortment of trees, shrubs and flowers, or it may be a work of art, lovely in the sum total of all of its beautifully fitted parts. Plants and trees are so decorative that their inherent beauty of form and of colouring will in themselves go very far towards rectifying mistakes in their arrangement and planting, but this quality should not be abused.

Gardens are essentially artificial, they cannot be otherwise, and their design and treatment should be a creation of art, and beautiful art at that. The composition of the picture should be so beautiful, so skilfully fitted and so perfectly balanced that to alter any part must necessarily to some extent spoil the whole of it.

There is, on every site, some atmosphere to appreciate, and to develop; something that will suggest itself as the *motif* or keynote, on which the whole harmony is to be built, and the garden maker should accentuate and not work in contradiction to this. On a flat site the most should be made of the spreading levels. If this is done small places will seem larger, and larger places very much more extensive.

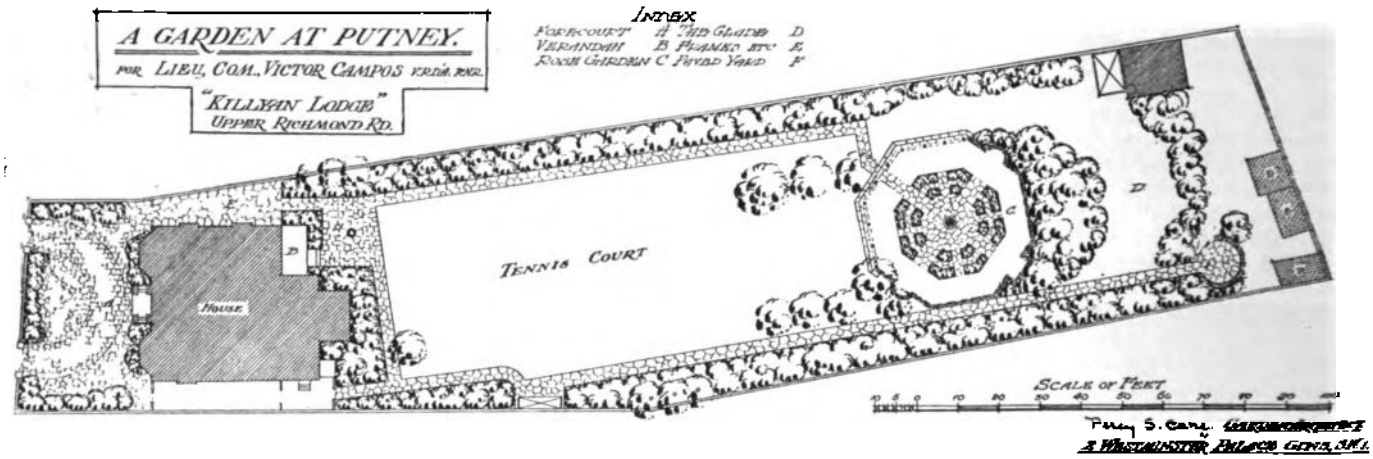
Just as level gardens are for flat sites, so are terraced gardens for hillsides, and for sloping ground. Advantage should be taken of distant scenes of special interest, and seats placed in such positions which command these views. From the terraced gardens of the Riviera, with their sub-tropical luxuriance of vegetation, are seen wonderful panoramas of sea and sky.

There is often, particularly in town gardens, the very opposite to this, because the distant view offers little that is beautiful or even interesting. In towns it is often desirable to block out surrounding buildings and overlooking windows with planting. In such a garden the interest must be entirely self-contained and if the site has no particular character, some definite feature must be introduced to give the necessary interest. This may be a sunk garden (but not, on a level site, sunk too much); it may, in a small garden, be some piece of statuary, or water could be introduced in some pool or tank, or more naturally with sloping grass banks and with aquatic plants growing into the water.

Whether it be a small or an extensive place, a garden will, if it has sufficient merit to rank as something of a work of art, possess a certain elusive quality; then the whole garden, no matter how large or how many its component parts, or how small, must form one definite entity complete in itself, with, so to speak, a beginning, a principal part or climax, and an end or boundary.

In the small garden this quality, although it should be none the less present, and its absence equally felt as something definitely missing, is less easy to define. It is made of the interweaving of line, or perhaps it is simpler to say the design of the garden, with a proper balance of form, with good arrangement and contrast of colour, and with connecting spaces of plain lawn. These plain spaces increase the value, and the pleasure to be derived from the sight of gardens full of colour, and are of considerable importance in the composition of the design.

Gardens of colour, and their many possibilities are known to most people, but how very effective gardens in which there are no flowers at all or only those of rather a special character can be, is not so fully appreciated. Even quite a small place, say from half an acre to an acre in extent, can be divided into several gardens, each with its distinctive character. The garden illustrated in the accompanying plan has a full size tennis lawn, flanked by borders on either side; there is a rose garden set amid fruit trees and flowering crabs. At the side of the rose garden the lawn leads into a little glade, which, with its berberis and other shrubs growing on to the turf from either side create, even in this London garden, a delightfully rural character.



Clipped golden yews planted symmetrically in the borders and the lawn give, by their repetition, length and definition to the flagged walks, on to the paving of which the low-growing plants in the front of the borders spread, in a beautiful unevenness of line.

The charm of a garden such as is illustrated is in the even flow of its lines, the proportionally long lawn continuing unbroken into the glade, which, enclosing the rose garden on its far side, returns without break into the opposite paved walk and so again to the terrace and house.

Except in definitely formal or perhaps in Dutch gardens, simplicity of line is incomparably better in its results than any fussy or complicated design. In a rose garden it is necessary to have separate beds and to plant one sort of rose only in each of them. But even here it is generally best to have a definite design, say rectangular beds with straight paths between, or (as shown in the plan), an octagon—or it might more simply be a square, in which every line is an essential part of the design.

In smaller gardens the boundaries should be covered with climbing plants, shrubs or hedges, unless they are, as is sometimes fortunately the case, of warm red brick walls. What is really a hedge, may with certain variety in the planting, and skill in the arrangement of the plants of which it is composed, be made to assume almost a woodland character in its irregularity and at the same time it will increase that most valuable enhancement of the beauty of any garden, contrast of light and shade.

PERCY S. CANE.

A HOLIDAY IN THE CANARY ISLANDS

BY DR. R. LLOYD PRAEGER

DEGOLLADA DE SAN SEBASTIAN (GOMERA).

FOR the final 500ft. of the ascent the path is very steep, and the mules clamber and stumble up the roughly paved zigzag track which climbs to the Degollada, or pass, on the knife-edge ridge above. The precipitous slopes to right and left face full south, and even now, in May, all the pretty annual plants which decorated the rocks are brown and dried. The autumn rains will wake their seeds to activity, through the winter months they will grow vigorously, February and March will see them in bloom, and before our home annuals are thinking of pushing up a tentative blossom their life-cycle will have run its course. But the hot rocks are still covered with plants of many sorts which rejoice in the dry sub-tropical conditions which prevail here. Notable among these are members of the sempervivum group. The cliffs are dotted with thousands of greenovias, with their rosettes of blue-grey leaves and fountains of golden flowers. Even more abundant is Sempervivum canariense, with large downy rosettes and spires of soft yellow blossoms. The glaucous S. Paivæ is here also, forming little round grey bushes with pinkish-white blooms; the dark green sticky S. viscatum, its golden flowers not yet showing; and still another white-flowered species, as yet undescribed. Numerous other fleshy plants are here too, and the vegetation resembles the Succulent House at Kew, glorified by glowing sunlight and magnificent mountain scenery.

We cross the pass to the northern slope—only a dozen paces—and what a contrast! One plunges at once into deep dark woods, through which the wind blows cool and damp. The trees, mainly heath (Erica arborea) and laurel (Laurus canariensis), are hung with dripping moss, among which many plants cling as epiphytes. The ground is one great fernery, with grand arching fronds 4ft. or 5ft. long. A dozen species are here, from the massive Woodwardia radicans to the tiny annual Gymnogramma leptophylla; while the crevices of the rocks are lined with the maidenhair and the curious undivided fronds of its cousin, Adiantum reniforme. Down the steep slopes Ranunculus cortusæfolius, with sprays of large golden blossoms on 3ft. stems, runs riot. After the glare of the southern slope our eyes require a minute or two to become accustomed to the dim green light, and then we discover innumerable smaller treasures—mosses and hepatics and delicate tiny herbs, all sparkling with dew, and green as emerald, while the wet wind that feeds them moans through the branches overhead.

PERSEA INDICA IN THE LAUREL FOREST (GOMERA).

We step once more across the pass, and we are back in the burning glare, windless and quivering, among the grey desert plants and the hot rocks. A black and white vulture soars, a thin wisp of smoke rises from the blue valley bottom 2,000ft. below,, and far beyond, like a red blot, are the roofs of San Sebastian, with the dim line of the Atlantic behind them.

A tall young peasant has joined my companions at the summit, his long *lanca*, an 8ft. jumping-pole with an iron point, in his hand, his heavy double-pocketed embroidered saddlebag at his feet. "Take care," he calls to me as I climb towards them, "that ground is dangerous"—as indeed it is. We chat a little, and then he swings his bag across his shoulders, waves a friendly farewell and, scorning the path, is off down the slope like a chamois.

LAVA AND CINDERS (LANZAROTE).

OUR camel grunts disgustedly at having three people imposed on him, but we pack on—one slung on either side, and one perched giddily between—and jolt, jolt! he is on his feet. The worst of a camel is that he gets up in jerks, first one end and then the other, and without practice one forgets which end goes up first. Consequently if one is absent-minded one may find oneself in the dust with disconcerting suddenness. We turn our backs on the houses and palm trees of Yaiza, and the lava confronts us instantly. This is only an arm of the great flows which fill all the valleys to the northward. It is barely a mile wide, but without the rough path that we are about to travel, that mile would be utterly impassable. The lava is like an ice-jam turned into black stone, a confused jumble of crests and troughs and great slabs up-ended or capsized, and so hard and glassy that one cannot so much as touch it without torn clothes and cut fingers. Our camel swings slowly and unconcernedly along the rough track, over mounds and into hollows, while our eyes seek in vain for any trace of life, animal or vegetable. We see, at last, a tiny fringe of green along a crack on a horizontal slab. It is a fern, of all things—an Adder's-tongue (Ophioglossum polyphyllum). How does it survive in this inferno, where in summer the heat radiated from the black well is mere torture?

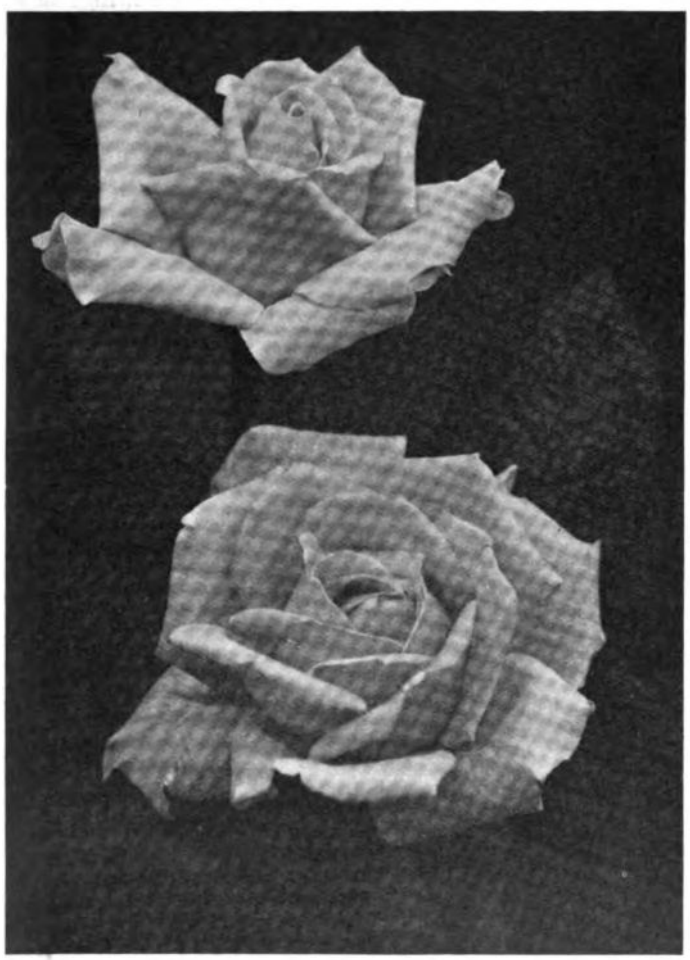
We near the opposite shore of our lava ocean. Gaunt bare hills face us, red and yellow and black, with a curiously smooth, velvety surface, on which these tints pass imperceptibly from one to another. We are soon on the slopes, to find that the mountains are composed of (or at least thickly covered with) cinders, of a uniform fineness, and packed so firmly that our footsteps hardly leave an impression. Again the eye ranges in search of life. Here is a solitary bush of the prickly Zollikoferia spinosa, all thorns, after the manner of Alyssum spinosum or Vella spinosa, dotted with tiny fragrant lettuce-like flowers, and few minute leaves. It is long before we see another plant, but there is a venturesome little colony of another desert thing, Polycarpæa Teneriffæ. We ascend steeply now (the camel being relieved of its encumbrances and turned loose to meditate on the strangeness of things). To the left is quite a grove of slender, erect stems on a steep, hot cinder slope. To our great surprise this is a British plant, Juncus acutus, which we associate at home with damp hollows in seaside dunes. Now we skirt the rim of a great crater, treading on yellow sulphurous crust. Our camel-driver feels with his hand, and says, "This will do." He scratches a hole a foot deep, burning his fingers in the process, drops in some eggs to cook for lunch. Then he sits down and lights a cigar.

Digitized by Google

Our eyes wander over miles of many-tinted mountains and deep craters and broad black plains devoid of tree or shrub or herb, for there are recent outpourings, some only two hundred years old and the ground is still hot in places, as it is here. To the south the hills are different, for they are much older. The surface has weathered into a thin soil, and at least in winter it is green with crops on the lower part, with nature herbs above. The fields and walls are grateful, for they remind us more of home and less of Dante's Inferno. "Los huevos son cocido," says the guide, and we fall to.

THE LAST SHOW OF THE YEAR

TUESDAY, December 16th, saw the last R.H.S. Show of the year at the Royal Horticultural Society's Hall, Westminster, and it was clearly evidenced by the number and quality of the exhibits, which were of a decidedly miscellaneous character, the main ones being garden sundries. True, a touch of colour was lent to the Hall by the floral effects of Messrs. Stuart Low, The Hon. Vicary Gibbs, The Caledonian Horticulturists, Messrs. Allwoods and Engelmann, and Baron Schröder. Again the onlooker was treated to a surfeit of artistic work, some of which was well executed. All those little things which assist in rendering the gardener's life more easy, such as plant stakes, labels, etc., were to the fore and it is well to give attention to the exhibits of sundries. One gathers much useful information which may stand one in good stead in the busy season.



ROSE COLUMBIA, AN EXCELLENT RECENT INTRODUCTION.

Fruit in the shape of apples was again in the capable hands of Messrs. Bunyard, in a small but well arranged table. Carnations although small in numbers were particularly fresh and bright, and were displayed by Messrs. Allwoods and Englemann. A collection of begonias was staged by Baron Bruno Schröder and although these gave every evidence of having been well grown, the colour was not all that could be desired, being of too blue a shade. As far as quality of bloom was concerned, the winter flowering begonias, shown by Messrs. Stuart Low, probably took the chief place. The flowers were of good substance and colour for this month. Like many other genera it has largely increased due to the untiring energies of collectors in the East and their new species coupled with the efforts of the hybridist, have given rise to many new and decidedly charming forms eminently suited for the garden. Chrysanthemums in point of numbers probably assumed the premier place, among the chief of the floral exhibits. The blooms were really good when one has regard to the inclement weather conditions of the past month. A very fine collection of hollies lent a Christmassy air to the meeting. These were sent by the Hon. Vicary Gibbs. They were well fruited specimens and gave one a fair idea of the width of this genus with its infinite variety in foliage and general habit.

Probably the finest stand was that of the Caledonian Strain Floriculturists, Putteridge, Luton, of which Mr. Forsyth is the Superintendent. This stand was unexpectedly gay and bright with varied flowers. The individuality of the blooms which were on show was well shown and the contrast was a good one. The main feature was probably the chrysanthemums, which included such varieties as Embleme Poitevene, a very good yellow with incurved florets, Mrs. George Monro, of a dark maroon shade, an excellent flower, Cheshunt White, with large decorative heads, and May Morris, a single, of bronze colour. The blooms were showing signs of the bad weather, and also probably suffered from travelling. These were bordered with cyclamens of the Caledonian giant flowering strain. Whites, pinks, mauves and reds mingled together in a pleasing array, although the frilled varieties did not appeal to us strongly. This strain appears to be a good one and may merit a trial from all cyclamen enthusiasts. The plants are of robust habit carrying flowers of large size, borne on erect, stiff stems; while the colours are pure. The exhibit at this time of the year reflects great credit on the Superintendent. Among the many exhibits were the following:

APPLES.—Messrs. Bunyard and Co.

BEGONIAS.—Baron Bruno Schröder, Stuart Low and Co.

CARNATIONS.—Messrs. Allwood Bros, C. Engelmann, Stuart Low and Co.

CYCLAMEN.—Messrs. Stuart Low and Co., Arthur Shambrook.

HARDY PLANTS.—F. K. Wood.

HOLLIES.—The Hon. Vicary Gibbs.

ORCHIDS.—Messrs. Saunders and Co.

SHRUBS.—Messrs. Bakers, The Orpington Nurseries.

VIOLETS.—Miss E. Heathcote, Baldwin Pinney.

LANDSCAPE.—Percy S. Cane, K. and E. Hopkins.

ARTISTS.—Edith Andrews, M. Aumonier, Maud G. Angell, Marion Broom, Edith Fisher, Agnes Foreman, Gladys Howse, Margaret Linnett, Mrs. Ethel Mayer, Mrs. Kirk Patrick, Mrs. Henny Spenser, Winifred Walker, Mrs. Russell Walker, Ellen Warrington, Alice Wilkinson.

HORTICULTURAL SUNDRIES, TOOLS, ETC.—Alice Baker (china bowls), Ashtead Potteries, Limited (china bowls), E. R. Buggé (sprays and powders), Chase Continuous Cloche Co. (adaptable plant protectors), Carter and Williams (labels and insecticides), Mrs. Dudley W. Duttson (unbreakable bowls), A. Everitt (gardening gloves), Thomas Gunn, Limited (tools), Hardy Patent Pick Co., Limited (spades), J. Jardine (Médoc and Guienne secateurs), London Garden Florists (flower bowls and containers), Saunders and Co. (Garden ornaments), Radium Fertilizer Co. (fertilisers), Mrs. E. Torkington (Wizard plant labels), S. and E. Wilson (portable frames), H. J. G. Wood (plant supports), Ymagynate Pottery (china bowls, etc.).

GARDEN BOOKS.—Cassell and Co., Ltd.

GARDEN CONTRACTORS.—Messrs. Johnstone.

JAMS.—Miss Dorothy Carter, Miss Hilda G. Sewell, Messrs. Westmacott, Co., Limited, Pickering Cottage, preserves (bottled fruit).

LAVENDER.—Miss Flora de Rheims.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

CHRYSANTHEMUM BALCOMBE BEAUTY.—A fine yellow Japanese variety, the blooms being of an average size and well formed, carried on robust stems. The florets are incurved in the interior of the flower, and deflexed on the exterior. Shown by A. G. Vinten, Balcombe, Sussex.

ROSE COLUMBIA.—This is a hybrid tea variety of the most excellent quality, in fact one of the finest roses we have seen for a considerable time. The blooms of a delicate blush pink colour are of a good shape and size. The outer petals are somewhat reflexed, while the calyx, made up of long sepals, is completely recurved. Through having been grown on the American system of double pinching, the result has been to produce long wiry stems, which add a decided gracefulness to the plants. In addition to all those qualities, the flowers have that old-time fragrance which of late years has been so elusive in the new productions of the rose hybridists. This is a variety which we must heartily recommend to all rose lovers. Shown by Messrs. Engelmann, Saffron Walden, Essex.

ORCHIDS.

CYPRIPEDIUM PERSEUS (Alcibiades × Lady Dillon). — An elegant hybrid of excellent formation and colour. The roundly formed dorsal sepal white, green at the base, heavily marked with crimson spots on the lower portion and with smaller spots on the white area. Petals and labellum broadly developed, shining mahogany red in colour, and margined with bright yellow. The clear yellow staminode is a conspicuous feature. This plant was originally in the well known collection of the late Mr. W. R. Lee, Plumpton Hall, Heywood, Lancashire, and received an Award of Merit when exhibited by him at the R.H.S., January 14th, 1919. It passed into the collection of Lieut.-Colonel Sir George Holford, K.C.V.O., and, under careful cultivation, has improved to the extent that a First-class Certificate has been awarded.

A Bronze Lindley Medal was awarded to Mr. S. Lyne, gardener to Mr. J. J. Bolton, Claygate, Surrey, for a superb specimen of Odontoglossum ardentissimum var. Pintadeau, with a branched spike having a total of eighty-three flowers.

NEW CHRYSANTHEMUMS.

At the last meeting of the season, December 15th, the Floral Committee of the National Chrysanthemum Society considered the merits of the following novelties.

BALCOMBE BEAUTY.—This is an especially valuable Japanese Chrysanthemum of market size and rich yellow colouring. It is a sport from December Bronze but the flowers are more substantial than that variety and it is said to be a much easier "doer." First-class certificate. Shown by Mr. A. E. Vinton.

DESIDERATUM.—This pure white variety was considered by the Committee to be too like a slightly incurving form of Autocrat to justify an award. But it is quite a desirable type of late-flowering chrysanthemum of medium size. Shown by Mr. W. Burden.

STEPHANIE.—As a large incurved Japanese variety for late season decoration this novelty has considerable value. The general colour is sulphur yellow and there is a fascinating peach bloom at the base of the florets which have exceptional substance. Shown by Messrs. Keith Luxford and Co.

NOTES FROM CONTRIBUTORS

CASSIA CORYMBOSA.

DURING a recent visit to the Penzance district of Cornwall, I noticed some very fine examples of the above plant, now rarely met with even in cool greenhouses. In the Morrab Gardens, Penzance, it is planted at the base of a wall, but in other places it is grown as a shrub. The plants were several feet in height, and covered with yellow flowers somewhat similar to the pea, the subject of this note belonging to the same natural order, Leguminosæ. It was introduced from Buenos Ayres in 1796, and it should be termed half hardy, only living outside throughout the year in such places as Penzance and other mild districts. In spite of this, however, I think it is worth a trial in other parts, where it can be protected during frosty weather, or the plants could be lifted directly the leaves are touched with frost, potted up, and stored in a cool greenhouse until the following May. When treated in this way, the plants may be cut back fairly hard at the time of lifting. Some years ago I grew a number of plants in this way in the South of England, and they were quite successful. A few cuttings were rooted annually, so as to keep up a stock of small plants, for planting out. It was very interesting to see Cassia corymbosa once again, and in such a flourishing condition. No doubt there are a number of Cornish gardens in which this plant would be an acquisition.—T. W. B.

GYPSOPHILAS.

IN the reorganising and preparing of flower borders to create something like order, one is sometimes tempted to disturb hardy plants that are best left alone. Gypsophilas are examples. The roots of these, as is well known, are deep-seated when they have been established a few years, and, being of a tender fleshy character, it is well-nigh impossible to lift them without mishap. Indeed, I have rarely met with any success following the disturbance of these herbaceous plants once they have been left to themselves; and, if doing well, the golden rule of "leaving well alone" is better to be observed. Considering that gypsophilas are easily raised from seed, and that plants begin to bloom in the second year and quite freely from the third, it is a mistake to meddle with established plants if it can be avoided. Further than this, propagation is almost as simply effected from cuttings taken about August and inserted in pans of sandy soil and placed in a cold frame. In one or two instances which have come under my notice, the reason assigned for taking up old plants and planting them elsewhere was that the flowering stems collapsed just before their time for opening. The real reason was that the soil in which the clumps were growing was deficient in lime, an important factor wherever these lime lovers are concerned. Soil which is known to lack this vital food needs to be replenished now and again with lime in some form, either superphosphate, old slacked lime, or mortar rubble. It is surprising the energy such gives to old and apparently worn-out roots of Gypsophila paniculata and its double counterpart.—CLAREMONT.

A TROPICAL VINE.

I ENCLOSE a photograph of a tropical vine which may interest readers who know it only in greenhouses. It is one of the most noticeable West Indian climbers, albeit hailing from Bengal—the Thunbergia grandiflora—which curtains porches, or jalousied rooms, or even fences. Among the bewildering array of bougainvillæas, jasmines, scarlet-tipped clerodendrons, and the like, one quickly distinguishes the huge leaves and flowers of this vine. The dependent stems form a verdurous screen curiously resembling a shingled surface. Elongated clusters of flattened velvety flowers as large as one's hand, sometimes richly purple, often white, hang like fringes, too heavy to be swayed by the "trades." Trained over arbours their massive leaves throw a warm shade beloved by orchids and ferns, which may be grown with successful results in such a position.—HELEN INGERSOLL, *N. Y.*

THUNBERGIA GRANDIFLORA ALBA, A NOTABLE WEST INDIAN CLIMBER.

DELPHINIUM NUDICAULE.

WHY one meets the name of this on almost every seed and hardy plant list, and yet so seldom comes across it in the gardens one visits, is a matter that would possibly be explained by the fact that it is small and herbaceous and therefore stands a good chance of being dug out during the annual clearing up of the flower borders. This may give the impression that it "dies out" from lack of hardiness, but nothing could be farther from the truth. Nudicaule *is* hardy and a very charming and attractive little plant, perfectly distinct from all other delphiniums. It is very easy to raise from seed, too, and one gets a generous packet for sixpence that will produce a large number of plants, while, if sowing is done early enough, one is gratified by a display of flower the first season. Not such a display as future years will afford, but a foretaste that is quite sufficiently fascinating to make one anxious for the "more" that will certainly come. One does not get the full height in the first season's flowering either, but ultimately the plants will attain a height of 18ins. The leaves are split into three divisions, each again much divided, and from the centre of each crown there pushes up a thin stem carrying the raceme of flowers. It is in the colour of these that one has to revolutionise one's ideas of the delphinium, for they are an intensely vivid red that hints of orange, the lower petals clear yellow. At the back of the flower is a long spur and the effect of a good colony of these in full bloom is brilliant in the extreme. The plant is suitable for good sized clumps, well forward in the hardy borders, and also splendid

Digitized by Google

in the rock garden, but, wherever planted, one must be certain that the site is well drained. With this single proviso, it is not at all fastidious in the matter of soil, but it does absolutely revolt against a wet and sour earth. When used in the border, the spot where it is planted should be conspicuously marked with a permanent label, otherwise there is a real danger of the tiny roots being forked out when digging is being done.—H. W. CANNING-WRIGHT.

PLANTING FLOWERS NEAR A DWELLING-HOUSE.

WHEN planting flowers in close proximity to the dwelling-house or a country cottage, the object contemplated should be a wise selection only of those plants best calculated to give a pleasing display, not merely over as long a season as possible, but able also to withstand a certain amount of dryness consequent upon the eaves of the house warding off a certain amount of rain.

This result can be attained by planting bulbs for spring flowering followed by nemesias, Canterbury bells, antirrhinums, pentstemons, etc., transplanted from the nursery or reserve garden when the bulbs have finished flowering; but the drawback to this method of culture is that one looks out upon bare earth during the dark months of the year.

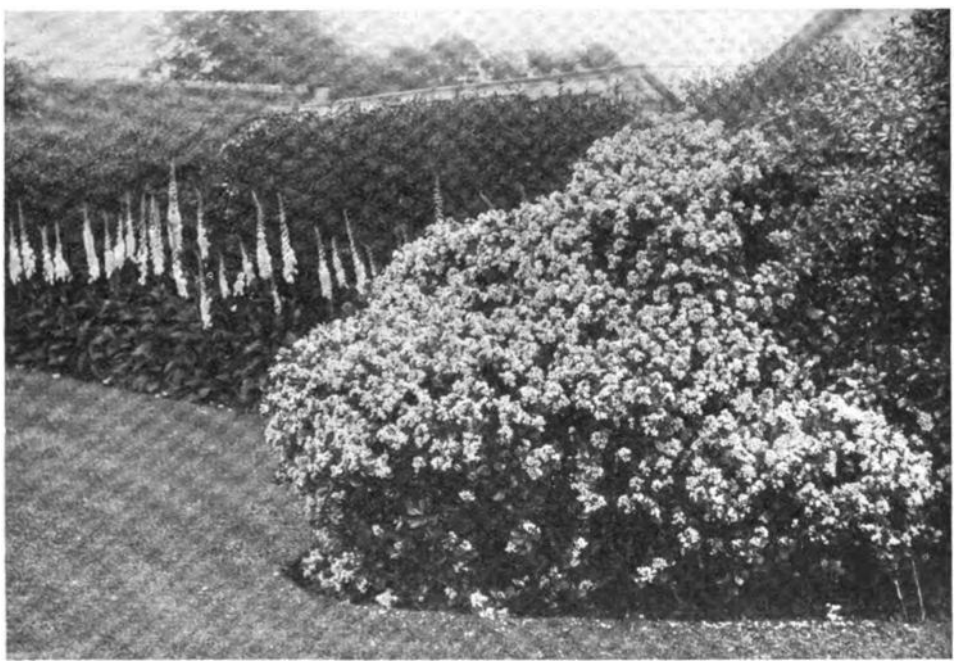
The procedure adopted at my new cottage has been to select plants the foliage of which remains green or a pleasing shade of grey all through winter. For instance, between the random paving and the cottage is a 5ft. border facing west. This is filled with Allwoodii, and as I write (November 12th) several sweetly scented flowers still gladden the eyes as one approaches from the lane. Passing the loggia and facing south is a carpet of Saxifraga Barthonii, green throughout winter and in spring one mass of rosy stars. Iris reticulata are planted among the cushions, and in February purple flowers make a welcome appearance above the rosettes, while English irises in June prolong the season of flowering. I find no drawback in having all three flowers in one bed, because I. reticulata has very little "grass," while the dead leaves of the English iris are easily plaited and thus kept from becoming unsightly.

Continuing along the crazy paving we come to a dry wall clothed principally with helianthemum, and the border looking towards the east is planted with Geum Mrs. Bradshaw and tones admirably with the helianthemum draping the wall. These have been in continuous bloom since May, and were only cut over last week because wet weather prevented other work on the land. We also find that their brilliant scarlet flowers contrast favourably with the paving—a mixture of limestone and ganister and quite hard.

An idea such as I have outlined, if carefully followed, would go a long way to solve the problem of garden monotony near the house. One thing is important before planting: see that the requisite plant food is provided when preparing the borders, not forgetting old builders' rubble or lime in some form for Allwoodii, because this part of the garden may not be dug over for some years.—E. E. P.

RAPHIOLEPIS JAPONICA.

SIR,—I am enclosing a photograph of Raphiolepis japonica, which I thought might prove of interest to readers of THE GARDEN. This particular shrub is nearly 5ft. high and the same distance through. The soil is light loam, with a subsoil of chalk. The situation is due south. It is growing in the garden of Mr. W. P. Matthews, The Old House, Walmer, Kent.—ALFRED GURR.



A FINE BUSH OF RAPHIOLEPIS JAPONICA IN KENT.

SHRUBS WITH COLOURED STEMS IN WINTER.

THOUGH many gardens are gay in summer, they are often dreary places in the winter-time, because there is nothing to relieve the dreadful monotony and drabness of the dead world. Even a plentiful leaven of evergreens does not brighten things materially, and so we would urge all to introduce at least a few shrubs whose stems are tinted with colour, particularly during the bare months of winter.

Most charming of all are the russet-brown and red twigs of the cornel berry or dogwoods, which, drooping in semi-pendulous showers, look well on the edge of a lawn and either against the grass or against snow. These shrubs are, indeed, pretty all the year round, for their foliage and flowers in summer are attractive and pleasing.

The white-stemmed bramble is another shrub, the effect in this case being due to its silvery stems; these stems grow to a great height and relieve the appearance of the shrubbery in winter. Rubus biflorus and R. leucodermis may both be grown, but the latter is the true white-stemmed variety. Certain willows are also noted for their brightness during winter. The red-stemmed and yellow-stemmed kinds are best; they revel in damp ground, though that is not absolutely essential, and they do well at the water-side.

Leycesteria formosa is an uncommon shrub, noted for the brilliant green of its twigs; it is particularly effective when snow is on the ground. Brown-stemmed plants are much more common, and among the brightest are Rubus spectabilis, Stephenandra flexuosa and Philadelphus Lemoinei. The flowering currant is pretty fair in this respect, too, and Polygonum cuspidatum looks well when bare; the latter, however, is one of the plants which need to be kept rigorously to their own corner.

From among the trees I want to single out for particular mention the several delightful varieties of the birch. I live in a "birch" district and, fortunately, see many pretty kinds quite near my own house; some have lovely bright silvery bark (I call this the silver birch); others have pendulous branches tipped with colour, and several more have a bright appearance which makes them always attractive.—CLYDESDALE.

IRIS ORCHIOIDES.

FEW of the numerous species of hardy bulbous irises appear to meet with so little favour from the purchaser of bulbs as Iris orchioides. It is, certainly, not so showy as many of the species, but it has several attractions, and it is quite distinct in its way from most of its sister flowers. It is an early bloomer, and appears too soon for some places, where its pretty pale green foliage sometimes suffers from late frosts, and if a succession of years occurs with such frosts there is a real danger of losing the plants from the bulbs becoming weakened. It is worth while, however, for those who are not troubled with late frosts to secure a bulb or two of I. orchioides. It is of pleasing habit and appearance, its light green foliage being of a charming texture and character, while its yellow flowers harmonise well with the leaves. It grows from 6ins. to 12ins. high and flowers in late spring or early summer. Bulbs should be planted at a depth of about 2ins. in light sandy soil or a compost of loam, leaf-soil or peat and sand. A warm, sunny border or corner of the rock garden should be chosen.—S. ARNOTT, *Dumfries*.

APPLE LORD DERBY.

IN a list of the best dozen apples, compiled a quarter of a century ago, or thereabouts, by the Royal Horticultural Society, the variety Lord Derby was included. This apple is one of the best for planting in cold, heavy soils, judging from experience with it here, growing in soil of this description.

Rather more than twenty years ago the vegetable quarters were extended, and, in addition to bush apple trees then planted in soil which had previously been under grass, sixteen standard trees were included. Of these sixteen, only five are standing to-day, two Lord Derbys, which look quite healthy and produce fine crops of good fruit; one Newton Wonder, which also does well, although it had silver leaf a few years ago. This disease disappeared after an extra heavy dressing of wood ash had been applied to the soil round the tree. The ash was obtained by burning a quantity of fir-tree tops. The remaining two apple trees are stunted specimens of Keswick Codlin, which, however, produce a useful addition of fruit to the culinary apples. The remainder of the trees originally planted looked well for a time, but

Digitized by Google

when they arrived at the stage at which they should have been fruiting, deteriorated by degrees, the young wood and fruit buds dying back considerably, especially after wet winters. The trees failing to fruit and presenting a hopeless appearance they were eventually cut down and used for firewood.

As the demand for vegetables was too great to allow the soil under the trees to be left untouched by the spade to any extent, the trees were no doubt injured by having the surface roots cut about when digging was performed, and the under soil being of an infertile nature considerable injury was probably the result.

To grow the choicer kinds of apples successfully where soil of the above description prevails, it is absolutely necessary to replace the uncongenial sub-soil with better soil in quantity; in the case of standard trees, "cartloads" instead of "barrow-loads" should be the term employed. In another part of the garden we have some standard trees of Blenheim Orange and Cox's, about fifty years old, which have done remarkably well and will apparently do so for some time yet. These are growing in a border about 10ft. wide, from which the clay appears to have been removed down to the chalk—the latter being about 4ft. from the surface—and replaced with soil. As there is a cart-road running parallel with the border, the soil and the clay probably were exchanged, to the great advantage of the fruit trees. To anyone contemplating the planting of apple trees where the soil is unsuitable, I would say plant a few well, with as much improvement of the soil as possible, rather than a number without any special preparation of the soil being made, especially in the case of choice varieties.—R. W. DEAN, *Audleys Wood Gardens, Basingstoke.*

SPRING FLOWERS IN WINTER.

WITH a very small amount of trouble it is easy to get quantities of spring flowers and foliage right in the middle of winter. Here are a few plans which are simple to carry out and do not cost anything at all. Branches of practically all the spring-blooming trees, such as almond, cherry (double and single), ribes and Japanese quince will open their blossoms beautifully if treated in this way: Cut boughs with plenty of flower-buds on them; these are easily distinguished from the buds which will only produce leaves by their larger size. Bring the branches indoors and then from the lower end of each pare away the bark for a distance of 2ins. or 3ins. Place in jars of water which is changed now and again, and keep the boughs in a warm, sunny room.

The buds develop rapidly and soon the flowers are out, completely transforming the appearance of the branches. Delicate spring foliage may be secured by treating shoots of horse chestnut and sycamore in just the same way. The catkins of the hazel and alder, as well as the shoots of the golden "palm," may be made to expand in water, and all these are extremely attractive for house decoration. Take up one or two roots of the common ferns from your rockery, or if you live in the country dig them up in the woods. Remove the clumps carefully in order to avoid any injury to the roots. Put the ferns into pots with a little soil and cut away any old or dead fronds. Keep in a warm living-room and moisten the clumps now and again with lukewarm water. In quite a short while the new fronds start to develop, and these are extremely delicate and of a bright green shade. In fact, the ferns resemble some of the rarer greenhouse specimens and form most desirable house plants. When the spring really does come the roots may be replanted on the rockery, and they will be little the worse for their experience.

Any of the common spring-flowering bulbs, with the exception of snowdrops, may be lifted from the garden border and put into pots or bowls. Care should be taken to avoid root injury and without delay the bulbs should be replanted in soil or fibre. For about a week keep in a rather dark position and then bring out into light and warmth. A place close to the window of a living room is splendid, and here the bulbs will develop quickly so that the flowers are in full beauty weeks ahead of the ordinary time. Many hardy plants can be treated with good results in a similar way. Such plants include wallflowers, forget-me-nots, arabis, polyanthus primulas, primroses and violets. In all cases get the plants into their new quarters as quickly as possible, and do not expose to a strong light for a few days. Remove any foliage that goes off and attend to the watering of the plants. It will not be long before the blossoms expand, and these are often produced over a long period.—S. LEONARD BASTIN, *Bournemouth.*

BOOK REVIEW

"Das Rosenbuch." Edited by Wilhelm Mütze and Camillo Schneider.
"Einjahrsblumen," by Paul Kache and Camillo Schneider.

THESE two books are the second and third of a series in course of publication by the German gardening magazine, *Gartenschönheit.* Both are interesting to the English gardener, not only for their information, but in showing the lines along which two branches of gardening are developing in Germany.

The rose book records a changing phase in rose growing that is apparently universal. The rose garden is described as a garden where the rose predominates in the picture without excluding other plants from it. Standard roses are admitted to it only under strictly limited conditions, and it is contrasted with the old "Rosarium," which aimed to be no more than a collection of choice varieties. A long, and perhaps the best section in the book is given to the species roses and others that may be grown to best advantage in the park and wild garden. It is significant that no place is given to roses for exhibition.

The cult of the rose is traced as it spread from Persia westwards into Greece, thence into Italy (where it shared in the decadence of the Roman Empire) and thence into central Europe. There it united with a native rose cult that had grown up round the wild dog rose and found its fullest expression in the religious and literary symbolism of the Middle Ages. The new roses from the Near East, Centifolia, Damascena and Gallica, crossed with one another and with the wild native roses, and we see the rose cult beginning to take on its modern form. A rapid development follows the discovery of artificial hybridisation, and thereafter the introduction of each new parent species gives a fresh impetus, and marks another step towards that visionary Rosa pefecta of the future that shall combine the excellence of all the roses. All through the first part of the book stress is laid upon the potentiality of the rose and upon its future; the latest development is looked for in California from the hybrids that have been raised there between R. gigantea and R. moschata, and the new group of single roses, of which Red Letter Day is the type, is welcomed as a fresh departure.

Sometimes an almost mystical enthusiasm obscures the subject and leads to indiscriminate superlatives of praise, for even the "wonder-plant of the world" is not always without its shortcomings. The later sections are more practical and very good, especially the chapters on the rose in the garden and the rose in the park. The author makes the valuable suggestion that winter-blooming shrubs, such as Jasminum nudiflorum, hamamelis and chimonanthus, should be planted in the rose garden to preserve a continuity of interest throughout the year.

It is strange that almost no attention is given to the scent of the rose, and it is to be hoped that the omission does not mean that the hybridists no longer take an interest in this quality, or that growers have ceased to value it.

The illustrations, especially the half-tones, are remarkably good, and we are very grateful for the reproductions of Redouté's delicate pictures of the old garden roses, which are not easily accessible to the ordinary reader.

In a book of several authors there is, almost inevitably, some overlapping and disagreement, but here the wide scope and breadth of treatment that collaboration makes possible outweigh the disadvantages, and "Das Rosenbuch" should find a permanent place in garden literature.

The book of annuals is, necessarily, of less interest to the English reader, for, although the annuals and the half-hardy perennials receive more attention in Germany than we commonly give them nowadays in England, yet the severe winters of central Europe make their culture more elaborate than with us and reduce the list of safely hardy annuals. The word "annual" is used in the purely gardening sense and includes biennials and a number of quick-growing perennials. The book provides, as others have done before it, a descriptive guide to the more commonly grown species, with directions for their cultivation. But it does more than its predecessors in giving a survey of the history of annual garden plants, beginning boldly in the ninth century with the opium poppy, though the author admits that it is only academically an "annual," since it was grown for its narcotic properties (which, luckily, soon deserted it in Europe). Annuals—except for marigolds, the hollyhock and Agrostemma coronaria, played, as a matter of fact, only a very small rôle in the flower garden until communication was opened with America and the Cape of Good Hope. Of later introductions it is interesting to learn that the sweet pea came into cultivation from a few seeds that were sent in 1699 from Siciliy to Dr. Uvedale at Enfield, where they soon began to show that variability that has served us so well ever since.

With very few exceptions only the ordinary and well known genera are mentioned (though the curious will find directions for growing the parasitic broom-rapes), and it is a pity that meconopsis and verbascum should find no place among the biennials nor the long-spurred columbines among the short-lived perennials.

The illustrations are even finer than those of the rose book, and some of the photographs, especially of the Japanese Morning Glory and the tobacco plant, are remarkably beautiful pictures. The colour photographs are much more successful than we usually find them in gardening books, but they do not reproduce the texture of the flower quite so well as the simple photographs do, and the colour values are apt to suffer a litt in consequence. The book is very well worth possessing as a gallery of flower portraits

DECORATIVE PLANTS FOR THE GREENHOUSE

ARDISIA CRENATA.—Among berried plants for winter decoration of the greenhouse and conservatory, this plant takes high rank, with its bright red fruit and dark evergreen foliage; it is also very useful for house decoration during the winter months. Few plants remain in good condition over such a long period, for in an ordinary greenhouse the fruit continues fresh and in good condition for at least six months. From seed this plant takes three years to attain a useful size; this many cultivators consider a serious drawback, but it need not be so if a batch is raised each year to maintain a regular succession. The seed should be sown early in the New Year, plunging the seed pots in a warm propagating case; germination will be hastened if the seed is soaked for twenty-four hours in warm water before sowing. The young seedlings should be placed singly in thumb pots, afterwards potting them on as they require it. Large pots are not necessary, as good plants can be grown in 5in. pots; in their fourth year they may be trimmed into the form of small standards and should have a shift into 6in. pots. During their growing period they should be given a temperature of about 60°. This plant is also easily propagated by means of cuttings placed in a warm case, but for this purpose leading shoots must be secured, as the laterals do not make good plants. It is somewhat subject to attacks of scale, which must be guarded against by sponging as they require it.

RIVINA HUMULIS, with its long racemes of small bright red fruits is very attractive for winter decoration in the warm greenhouse, where a night temperature of about 50° can be maintained. Although perennial, this plant is usually treated as an annual, as it is easily raised from seed sown some time during March for winter use. If required for the summer months seed should be sown in an intermediate temperature about the middle of September, the plants during the summer months standing quite well in a cool greenhouse. Its successful cultivation presents no difficulty as it grows quite well in any good potting compost, and in a temperature of about 50°. It is also easily propagated by means of cuttings, although seed affords the best means of increase. Good useful plants for the stages can be grown in 5in. pots. Although generally treated as an annual this plant can be grown on in large pots, when it will make a specimen some 3ft. to 4ft. in height. It also makes a fine bush if planted out in a well drained bed or border in the conservatory.

BEGONIA FUCHSIOIDES.—This beautiful begonia, which was introduced from New Grenada in 1846, at one time common in gardens, is now very seldom seen, which is a pity, as it is a very beautiful plant, and used to be commonly grown for winter flowering; in this respect it has, however, been superseded by the many useful and beautiful B. socotrana hybrids. B. fuchsioides is, however, deserving of more general cultivation, as it produces its beautiful red flowers more or less all the year round, and is perhaps seen at its best when planted out in a well drained border and trained up a pillar or back wall. On a wall where the growths can be given room and trained out it will cover a large space and attain a height of some 8ft. to 10ft. This species is easily propagated by means of cuttings, which root readily in a warm case.

FORCING PLANTS.—In forcing plants for the conservatory and greenhouse, there are many hardy shrubs and small flowering trees which can be employed, and these may either be purchased or grown at home in the reserve garden. In any case many of them may be used for years if planted out in the reserve garden for a year or two to recover. If not already done, no time should be lost in securing and potting up the required plants. Many of them are best when pot grown and such plants can be purchased from firms who specialise in this work. Although they are more expensive, it pays in the end. For example, a pot-grown lilac will remain in good condition for several weeks in a cool conservatory, while one lifted from the ground and potted during the autumn will probably only last a week, and this is also true of such plants as pyrus and prunus. After potting, the plants should be stood out in an open position, plunging the pots to the rim in ashes, as well as protecting them with hay, this to prevent the pots being damaged by frost. Here they will remain until such time as they are required for forcing. There is a wide range of plants that may be used for this purpose, including such well known plants as Pyrus floribunda and its varieties atro-sanguinea and purpurea, P. spectabilis and the hybrid P. Scheideckeri. Quite a number of prunus are also very useful including the Japanese cherries, P. Pissardii, P. triloba fl. pl., P. sinensis, with double flowers in rose and white varieties, all the beautiful double-flowered peaches and P. subhirtella. Azaleas in many beautiful varieties are also largely used for this purpose, as well as many of the earlier flowering rhododendrons, RR. præcox and Rosa Mundi being specially useful for early work. All the hybrids with Caucausicum blood in them are well suited for forcing as are also Acer Negundo var. variegata, and the many beautiful varieties of Japanese maples. Kerria japonica var. fl. pl., although rather short-lived is very useful for early work. Spiræas, include arguta, Thunbergi, prunifolia fl. pl. and the hybrid Van Houttei. Deutzia gracilis is, of course, well known, but some of the other newer species should be equally useful when better known. Good pot-grown plants of wistaria are very beautiful; they should be brought on fairly cool, for if given too much heat their buds are apt to drop off. Viburnums include the "Snowball Tree," V. Opulus var. sterilis, V. Tinus and the beautiful fragrant V. Carlesii. This last species is best when not subjected to too much heat. Forsythia suspensa is also very useful, but the best for this purpose is F. intermedia var. spectabilis, with deep golden yellow flowers, which are produced in wonderful profusion and remain in good condition for several weeks, cut sprays being very useful for house decoration. This fine forsythia may, with gentle forcing, be had in flower for Christmas. Magnolias are also very useful, well flowered plants of M. stellata being very beautiful. Well grown plants of Nevinsa alabamensis, with feathery looking white flowers, is very beautiful and might be more generally used for forcing. As this brief note indicates there is a wide choice of beautiful plants for this purpose. J. COUTTS.

ONE OF THE DOUBLE FLOWERED VARIETIES OF THE PURPLE LEAVED PRUNUS PISSARDII.

THE SALPIGLOSSIS.

NOTWITHSTANDING the increased interest shown in the culture of annuals during the last decade or so, there is, I think, a fear lest some of them should be overlooked. The criterion of value with many blossoms to-day is their suitability for cutting, and, if they do not come within this category, there seems to be a disposition to drop them. Is this not borne out in the case of the balsam and also, though possibly in a lesser degree, the salpiglossis? Time was when the former was cultivated as a pot plant much more than it is to-day, and this was because its beauty was recognised, although the flowers are of no import to the one who studies only blossoms fit for cutting. The salpiglossis seems to have lost what popularity it once had, though it may be employed for summer bedding or for indoor growing, where its funnel and daintily veined blossoms are seen to great advantage. It has been noticed that at many provincial shows the exhibitors who show them in pots are a decreasing number, and there seems a possibility of such a charming annual being allowed to drop out altogether.—CLAREMONT.

SIMPLE GARDENING

PRIMULAS, CINERARIAS AND CYCLAMEN.

OUR greenhouses and conservatories would not be so well filled as they usually are from autumn to late in spring, if we did not cultivate well the three kinds of plants above named. But, unless the plants are well grown they are not of much use to us. One may say this of all kinds of plants, but good culture makes a big difference in the case of the plants we are now dealing with. As fuel is expensive, the plants are economical to grow on this account, but for themselves and their general welfare, a comparatively low temperature is best. Some of my primulas were slightly frozen in a frame this autumn, but as the sun's rays were kept off by shading the following day they did not suffer any harm. Of course, the plants should not be subjected to a frosty air, and from this date onwards we should be prepared to exclude frost. Many inexperienced cultivators make a mistake when they feed these plants with artificial manures. Their roots are very fine—thread-like—and are soon damaged. Err on the side that will result in healthy plants if smaller ones, by using clear water only during the months of January and February. Dry stages are not ideal as a base for the plants; shingle or spent ashes, small cinders, are the best. Do not mix the kinds, but keep them separate till the flowers are forward enough to make effective mixed groups. Admit plenty of air without risking cold draughts.

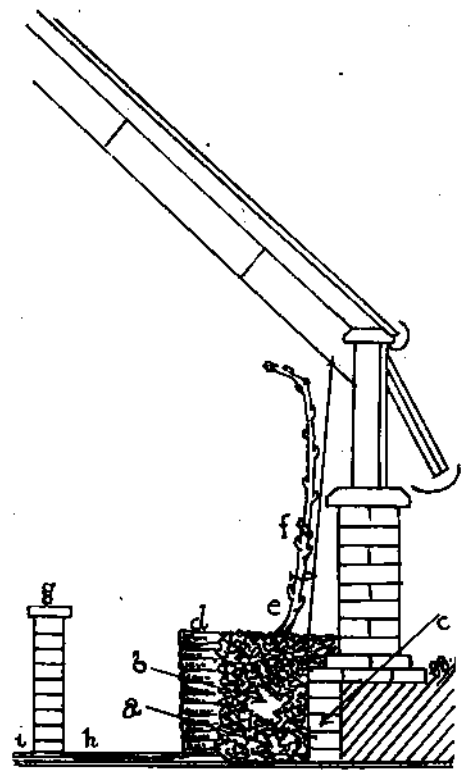
PLANTING CLIMBERS IN THE CONSERVATORY.

The kind of climber to be planted will be determined, to a great extent, on the position or aspect of the structure. One facing north and, perhaps, also overshadowed by high buildings would not be suitable for climbers generally. Only in special cases would such plants be grown if others in pots were required, too, notably those that flowered. Fully exposed, warm conservatories are suitable for climbers. Indeed, such structures are all the more inviting for the presence of overhead foliage. The present is a good time for preparing borders, tubs or large pots for the plants to occupy them in early spring. A good general compost is one made up as follows: Fibrous loam, two-thirds; half-rotted leaf-soil, one third. Peat-loving plants may have fibrous loam two parts, leaf-soil one part and peat one part; if the latter is not available, more leaf-soil in a nice flaky condition should be included. Old lime rubble is good for the majority of these plants. The sand used should be coarse silver sand, or ordinary sand well washed and dried. It is an advantage to mix the composts and construct the borders or fill the tubs several weeks prior to planting the climbers in them.

Few kinds usually referred to as climbers are really true to the character; they need supports and, in due course, to be fastened to them. In large structures the following are suitable: Bougainvillæa glabra, Clematis indivisa lobata, Cobæa scandens variegata, Passiflora Constance Elliot, Tacsonia Van Volxemi, Solanum jasminoides, Plumbago capensis and tecomas. All should be planted from pots.

MAKING NEW VINE BORDERS: PLANTING.

Vines may be successfully planted in mid-winter or in May when young shoots are growing. Undoubtedly, it is safest for the amateur, or the cultivator who is now commencing the work of growing grapes, to plant the young vines in the winter while the buds are dormant. Where the subsoil is clayey and drainage difficult, vines are better in an inside border; but where the natural soil is good and drainage ample the vines may be planted inside and the roots allowed



to permeate the outside border through arches built in the front wall. Old upland grassland provides the best turves, if such can be obtained. In every case, the most fibrous turf should be used, and it does not matter how fresh it is, as the grass and fibre will rot in the border, providing food for the vine roots in due course. The turves should be carefully examined and wireworms extracted if any infest the turf available. Rotted manures are not required in a vine border, all such are best applied on the surface. Whether drains are laid or not, clinkers or broken bricks should be laid down from 4ins. to 7ins. deep as shown at *a*; then whole turves, grass side downward, are laid on them, the remaining 2ft. being filled with chopped turves and sprinkling of ½in. bones. The letter *c* shows the retaining wall for the bulk of the border soil *b*, and *d* shows the front wall of turves which are buried in due course, as borders are best made in sections. The letter *e* shows how to plant the vine and fasten it, loosely, to a stake; *f* shows where the cane should be cut off. The letter *g* shows the inner wall; *h*, border space to be filled; and *i*, path in the vinery.

A CHAT ABOUT EARLY VEGETABLES.

Cultivators who possess gardens surrounded by walls have an advantage over those whose gardens are fully exposed. On the warm border at the foot of a wall facing south, or south-south-east, early potatoes, peas, beans, carrots, turnips, radishes, lettuces and spinach may be grown, the resultant produce being available for use one month to six weeks earlier than that raised in the exposed garden. In the latter raised beds are helpful, but not those with flat surfaces all equal in height; the bed should slope 6ins. to 9ins. in a width of 4ft., the highest side being on the north or north-east and the lowest on the direct opposite. Moreover, the surface soil, when seeds have been sown, must be left in a rather lumpy state When I first began to take an interest in gardening, I observed closely the work of others and noted the "finish" they made to their early seed beds in spring by patting down all lumps with the back of a clean spade. Not a single experienced cultivator will do it now. It is wrong, because at this early date the soil below the surface is very moist and cold, and air is thus excluded; it is wrong, because the cold east winds sweep over the unprotected seedlings, checking their growth. Even lumps 1in. across are as hills to the tiny seedlings, and so afford them some protection against the chilling winds. A stock of really nice dry soil is a great asset, too; directly the seeds are sown they should be lightly covered with the dust-dry soil before the ordinary loam is replaced on them.

ABOUT FLOWER POTS, BOXES, AND SEED PANS.

In every garden stocks of seedlings and young plants are grown during the late winter and early spring months. For their accommodation the above receptacles are required and should be ready for use when needed. It is not enough that they should be at hand, they must be clean and dry, too. We will consider the boxes first; old ones, having insecure bottoms, may be turned upside down and new boards nailed on, thus making them sound enough for one more season's use. Very old ones should not be used again, and all old boxes should be well lime-washed inside, then stored away in a dry shed. The lime wash will kill any fungus adhering and be beneficial to the young plants. If new boxes are to be made, use three-quarter inch boards, have several holes in the bottom of each one or so nail on the bottom boards that a narrow space is left between them for drainage. two narrow strips of wood nailed across the bottom, 3ins. from each end, will prevent the wood unduly rotting on a damp base and ensure ample drain.

GEORGE GARNE

ANSWERS TO CORRESPONDENTS

THE FLOWER GARDEN.

The Treatment of Chrysanthemum Cuttings (F. V.).—It is advisable to keep all suckers on old roots intended for use in February as cuttings in a cool structure but safe from being frozen. They should be about 2ft. below the roof glass, and not nearer than 6ins. Air should be admitted freely in fine weather and damp guarded against. If the cuttings are growing thickly, thin out a few of the weakest. Apply clear water as required.

Which are the Best Varieties of Primulinus Hybrids Easily Grown? (W. H. L.).—Given good soil, an open situation and reasonable attention, I think that the following twelve varieties will give general satisfaction: Alice Tiplady, soft orange saffron self; Fire Queen, bright scarlet; Hermione, orange salmon; Linton, salmon rose, ruffled petals; Nydia, pink shaded rose; Pansy, salmon red with dark blotch, very distinct; Salmon Beauty, fine clean flower; Sedan, pale yellow with crimson bar; Souvenir, yellow; Topaz, salmon pink and buff; Zenobia, orange red; Van Limburg Stirum, very pale pink. If, however, a further six should be required, try Butterboy, a very fine soft yellow; Cassandra, salmon buff; Canonite, orange; Jewel, salmon pink, yellow blotch; Myra, salmon flushed on yellow ground; Orange Brilliant. With the exception of Butterboy and Pansy, I have grown all the above for some years. Orange Brilliant may, perhaps, be the one that has been a little shy, but it is so distinct that it must be included. Pansy is a new one, but a very free grower. Butterboy is also new and a very refined flower.—G. C.

THE FRUIT GARDEN.

Strawberry Varieties (Tinus).—The following strawberry varieties are of good size and flavour and are given in order of ripening. *Early*.—The Duke, King George V, Royal Sovereign. *Second Early*.—Kentish Favourite. *Mid-Season*.—Laxtonian, James Veitch, Madame Kooi. *Late*.—Givon's Late Prolific, Waterloo.

"Sleepy" Pears (K. A.).—A "sleepy" pear is one with the portion of flesh around the core soft and spongy; this condition gradually spreads to the outer rind. Early varieties go sleepy sooner than later ones and should always be gathered before they are quite ripe. Some varieties of poor flavour turn "mealy" sooner than others. A good loam, inclined to be clayey, is the ideal soil. In very light soils the fruits are more liable to become sleepy, and also crack more than those grown in a heavier soil. Sleepy fruits become so because the natural sugar in them fails to coagulate and preserve the flesh. It is, really, a sour condition.

Seakale Cultivation (W. S. F.).—You should have no difficulty in growing seakale. During the autumn or winter purchase roots for planting. The roots should be planted about 2½ft. apart in well cultivated ground. If it is intended to force them on the ground it is a good plan to plant them in groups of three. For future supplies stock can be kept up by means of root cuttings. For this purpose select pieces of root about 4ins. in length and plant them out in permanent positions some time during March. By planting some sets each year you will be able to keep up a supply of strong plants. If you desire to use seakale pots for forcing on the ground, they can usually be procured from any reliable nurseryman. However, these pots are really not necessary, as large ordinary flower-pots will answer the same purpose, or boxes may also be used. When forcing on the ground, all decaying leaves, etc., should be cleared away from the plants, and some clean ashes placed round the crown of the plants. Place the pots or boxes over them and cover with leaves and stable manure mixed to make a hot-bed. Care should be taken that it does not become too hot and burn the plants. If not required during winter, seakale can be blanched during the spring by simply covering it with sifted ashes or sand, or even clean dry leaves. If done in this way the quality is usually superior to that of the plants forced earlier in the year. Without seeing a specimen of your fuchsia we cannot name it.

FRUITS UNDER GLASS.

Grapes Unsatisfactory (J. B.).—The variety, bunches of which are sent for examination, is Muscat Hamburg, commonly known as the Black Muscat. It is a high quality grape in every way, but requires to be grown in a heated structure to reach perfection. Insufficient heat when the vines began to grow and in the autumn just before the berries coloured is the cause of many berries failing to colour, coupled with a too wet state of the soil. Do not fork up the surface soil more than 2ins. deep at any time, and do not damage any roots. Remove loose surface soil now and apply a dressing of lime at the rate of 1lb. per square yard, and 4 oz. of bone-meal. Then add 3ins. of roughly chopped fibrous turf.

MISCELLANEOUS.

Snails and Slugs (E. F. B.).—We presume that you refer to slugs, mainly. Owing to fewer birds in our gardens during the past three years—chiefly blackbirds and thrushes—shell snails have become a plague in many gardens, and the wet season has favoured the slugs. There is no chemical preparation that can be used to destroy the slugs without injuring plants. Soot and lime will deter them and benefit the plants too. The only effective way is to hunt for and destroy shell snails late in the evening. Ducks will soon clear a garden of slugs and not damage any crops while slugs are available. Then the ducks should be removed, and turned in again when the tiny slugs, deep in the soil, have grown a little. One hour or so each day would be sufficient.

How to Destroy Earthworms (A. G.—A very simple home-made solution for destroying earthworms in lawns is the following. Place 1 peck of fresh, unslaked lime in a tub containing 10 gallons of water and add a handful of chloride of lime. Stir thoroughly, then allow the lime to settle, using the clear water, applying it through a rosed watering can. The worms will come to the surface and should be brushed up. Larger quantities should be prepared if there are conveniences. Messrs. Sutton's, Reading, and Messrs. Carter, Raynes Park, issue very useful books on lawns and their general treatment. The watering should be thorough.

Fungus on Scotch Pine Needles (A. H. H M.).—The fungus present on the needles is Sclerophoma pityophila. Little is known about the pathology of this fungus. It needs working out, and as the trouble is reported from one or two other localities it will probably receive attention in the near future. If practicable it would be wise to collect and burn the fallen needles. Spraying beneath the trees with a solution of copper sulphate would help in the extermination of the fungus. As, however, you have shrubs growing beneath the trees, it will only be possible to use a weak solution.

YOU CAN GIVE NO BETTER GIFT

to your friend, either at home, in the Colonies, or abroad, than a weekly copy of

THE GARDEN

It means 52 remembrances of friendship in the year

Established 1796.

ARTINDALE'S PLANTS ALWAYS PLEASE

BEAUTIFUL FLOWER GARDENS

SHOULD you contemplate making a new Flower Border or adding to your collection, write for our new Catalogue of Hardy Plants. We can supply your requirements and give satisfaction. We guarantee to supply strong healthy clumps (not miserable offsets as are so often supplied).

In Open Competition this year we have gained the following awards:

1st Prize. Royal Agricultural Show, Leicester, for Group of Hardy Flower roots. **1st Prize.** Royal Agricultural Show, Leicester, for Herbaceous Border. **1st Prize.** Yorkshire Show, for Herbaceous Group. **1st Prize.** Saltaire Rose Show, for Herbaceous Group. **Gold Medal.** North of England Horticultural Society, for Herbaceous Flower Border. **1st Prize.** Leeds, for Herbaceous Flowers. **1st Prize.** Southport, for Collection of Gladioli. **1st Prize and Gold Medal** Huddersfield, for Hardy Flowers.
